When you pass the logical ID of an `AWS::DMS::ReplicationInstance` resource to the intrinsic `Ref` function, the function returns the replication instance ARN.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
```

```
    "BasicReplicationInstance": {
      "Type": "AWS::DMS::ReplicationInstance",
      "Properties": {
        "ReplicationInstanceClass": "dms.t2.small"
      }
    }
  }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  BasicReplicationInstance:
    Type: AWS::DMS::ReplicationInstance
    Properties:
      ReplicationInstanceClass: dms.t2.small
```

See Also

- CreateReplicationInstance in the *AWS Database Migration Service API Reference*.
- AWS CloudFormation Stacks Updates (p. 120)

AWS::DMS::ReplicationSubnetGroup

The `AWS::DMS::ReplicationSubnetGroup` resource creates an AWS DMS replication subnet group. Subnet groups must contain at least two subnets in two different Availability Zones in the same region.

> **Note**
> Resource creation will fail if the `dms-vpc-role` IAM role doesn't already exist. For more information, see Creating the IAM Roles to Use With the AWS CLI and AWS DMS API in the *AWS Database Migration Service User Guide*.

Topics

- Syntax (p. 1109)
- Properties (p. 1110)
- Return Value (p. 1110)
- Example (p. 1111)
- See Also (p. 1111)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::DMS::ReplicationSubnetGroup",
  "Properties" : {
    "ReplicationSubnetGroupIdentifier" : String,
    "ReplicationSubnetGroupDescription" : String,
    "SubnetIds" : [ String, ... ],
    "Tags" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: AWS::DMS::ReplicationSubnetGroup
Properties:
  ReplicationSubnetGroupIdentifier: String
  ReplicationSubnetGroupDescription: String
  SubnetIds:
    - String
  Tags:
    - Resource Tag
```

Properties

`ReplicationSubnetGroupIdentifier`

The identifier for the replication subnet group. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the identifier.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ReplicationSubnetGroupDescription`

The description for the replication subnet group.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`SubnetIds`

The EC2 subnet IDs for the replication subnet group.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`Tags`

The tags that you want to attach to the AWS DMS replication subnet group.

Required: No

Type: A list of resource tags (p. 2258) in key-value format.

Update requires: Replacement (p. 121)

Return Value

Ref

When you pass the logical ID of an `AWS::DMS::ReplicationSubnetGroup` resource to the intrinsic `Ref` function, the function returns the name of the replication subnet group, such as `mystack-myrepsubnetgroup-0a12bc456789de0fg`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myReplicationSubnetGroup" : {
         "Type" : "AWS::DMS::ReplicationSubnetGroup",
         "Properties" : {
            "ReplicationSubnetGroupIdentifier" : "identifier",
            "ReplicationSubnetGroupDescription" : "description",
            "SubnetIds" : [ "subnet-7b5b4112", "subnet-7b5b4115" ],
            "Tags" : [ {"Key" : "String", "Value" : "String"} ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  myReplicationSubnetGroup:
    Type: AWS::DMS::ReplicationSubnetGroup
    Properties:
      ReplicationSubnetGroupIdentifier: "identifier"
      ReplicationSubnetGroupDescription: "description"
      SubnetIds:
        - "subnet-7b5b4112"
        - "subnet-7b5b4115"
      Tags:
        -
          Key: "String"
          Value: "String"
```

See Also

- CreateReplicationSubnetGroup in the *AWS Database Migration Service API Reference*.
- AWS CloudFormation Stacks Updates (p. 120)

AWS::DMS::ReplicationTask

The `AWS::DMS::ReplicationTask` resource creates an AWS DMS replication task.

Topics

- Syntax (p. 1111)
- Properties (p. 1112)
- Return Value (p. 1114)
- Example (p. 1114)
- See Also (p. 1114)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type": "AWS::DMS::ReplicationTask",
  "Properties": {
    "CdcStartTime": Timestamp,
    "MigrationType": String,
    "ReplicationInstanceArn": String,
    "ReplicationTaskIdentifier": String,
    "ReplicationTaskSettings": String,
    "SourceEndpointArn": String,
    "TableMappings": String,
    "Tags": [ Resource Tag, ... ],
    "TargetEndpointArn": String
  }
}
```

YAML

```
Type: AWS::DMS::ReplicationTask
Properties:
  CdcStartTime: Timestamp
  MigrationType: String
  ReplicationInstanceArn: String
  ReplicationTaskIdentifier: String
  ReplicationTaskSettings: String
  SourceEndpointArn: String
  TableMappings: String
  Tags:
    - Resource Tag
  TargetEndpointArn: String
```

Properties

`CdcStartTime`

The start time for the Change Data Capture (CDC) operation.

Required: No

Type: Number, epoch value in milliseconds

Update requires: No interruption (p. 120)

`MigrationType`

The migration type.

`Valid Values`: `full-load`, `cdc`, `full-load-and-cdc`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ReplicationInstanceArn`

The Amazon Resource Name (ARN) of the replication instance.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ReplicationTaskIdentifier`

The ARN string that uniquely identifies the endpoint.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ReplicationTaskSettings`

Settings for the task, such as target metadata settings. For a complete list of task settings, see Task Settings for AWS Database Migration Service Tasks in the *AWS Database Migration Service User Guide*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SourceEndpointArn`

The ARN string that uniquely identifies the endpoint.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`TableMappings`

The JSON that contains additional parameter values.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Tags`

The tags that you want to attach to the migration task.

Required: No

Type: List of resource tags (p. 2258) in key-value format

Update requires: Replacement (p. 121)

`TargetEndpointArn`

The ARN string that uniquely identifies the endpoint.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Value

Ref

When you pass the logical ID of an `AWS::DMS::ReplicationTask` resource to the intrinsic `Ref` function, the function returns the replication task ARN.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
    "myReplicationTask": {
      "Type": "AWS::DMS::ReplicationTask",
      "Properties": {
        "SourceEndpointArn": 11,
        "TargetEndpointArn": "12ff",
        "ReplicationInstanceArn": "ert1",
        "MigrationType": "full-load",
        "TableMappings": "{ \"rules\": [ { \"rule-type\": \"selection\", \"rule-id\":
 \"1\", \"rule-name\": \"1\", \"object-locator\": { \"schema-name\": \"%\", \"table-name\":
 \"%\" }, \"rule-action\": \"include\" } ] }"
      }
    }
  }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  myReplicationTask:
    Type: AWS::DMS::ReplicationTask
    Properties:
      SourceEndpointArn: !Ref SourceEndpoint
      TargetEndpointArn: !Ref TargetEndpoint
      ReplicationInstanceArn: !Ref ReplicationInstance
      MigrationType: "full-load"
      TableMappings: "{
        \"rules\": [
          {
            \"rule-type\": \"selection\",
            \"rule-id\": \"1\",
            \"rule-name\": \"1\",
            \"object-locator\": {
              \"schema-name\": \"%\",
              \"table-name\": \"%\"
            },
            \"rule-action\": \"include\"
          }
        ]
      }"
```

Amazon DynamoDB Resource Types Reference

This section contains reference information for all Amazon DynamoDB resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::DynamoDB::data-type-name
```

Topics

- AWS::DynamoDB::Table (p. 1115)

AWS::DynamoDB::Table

The `AWS::DynamoDB::Table` resource creates a DynamoDB table. For more information, see CreateTable in the *Amazon DynamoDB API Reference*.

You should be aware of the following behaviors when working with DynamoDB tables:

- AWS CloudFormation typically creates DynamoDB tables in parallel. However, if your template includes multiple DynamoDB tables with indexes, you must declare dependencies so that the tables are created sequentially. Amazon DynamoDB limits the number of tables with secondary indexes that are in the creating state. If you create multiple tables with indexes at the same time, DynamoDB returns an error and the stack operation fails. For an example, see DynamoDB Table with a DependsOn Attribute (p. 1122).
- Updates to `AWS::DynamoDB::Table` resources that are associated with `AWS::ApplicationAutoScaling::ScalableTarget` resources will always result in an update failure and then an update rollback failure. The following `ScalableDimension` attributes cause this problem when associated with the table:
  - dynamodb:table:ReadCapacityUnits
  - dynamodb:table:WriteCapacityUnits
  - dynamodb:index:ReadCapacityUnits
  - dynamodb:index:WriteCapacityUnits

  As a workaround, please deregister scalable targets before performing updates to `AWS::DynamoDB::Table` resources.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::DynamoDB::Table",
  "Properties" : {
    "AttributeDefinitions" : [ AttributeDefinition, ... ],
    "GlobalSecondaryIndexes" : [ GlobalSecondaryIndexes, ... ],
    "KeySchema" : [ KeySchema, ... ],
    "LocalSecondaryIndexes" : [ LocalSecondaryIndexes, ... ],
    "PointInTimeRecoverySpecification" : PointInTimeRecoverySpecification (p. 1131),
    "ProvisionedThroughput" : ProvisionedThroughput,
    "SSESpecification" : SSESpecification,
    "StreamSpecification" : StreamSpecification,
```

```
    "TableName" : String,
    "Tags" : [ Resource Tag, ... ],
    "TimeToLiveSpecification" : TimeToLiveSpecification (p. 1135)
  }
}
```

YAML

```
Type: AWS::DynamoDB::Table
Properties:
  AttributeDefinitions:
    - AttributeDefinition
  GlobalSecondaryIndexes:
    - GlobalSecondaryIndexes
  KeySchema:
    - KeySchema
  LocalSecondaryIndexes:
    - LocalSecondaryIndexes
  PointInTimeRecoverySpecification:
    PointInTimeRecoverySpecification (p. 1131)
  ProvisionedThroughput:
    ProvisionedThroughput
  SSESpecification:
    SSESpecification
  StreamSpecification:
    StreamSpecification
  TableName: String
  Tags:
    - Resource Tag
  TimeToLiveSpecification:
    TimeToLiveSpecification (p. 1135)
```

Properties

`AttributeDefinitions`

A list of attributes that describe the key schema for the table and indexes. Duplicates are allowed.

Required: Yes

Type: List of AttributeDefinition (p. 1128)

Update requires: Some interruptions (p. 121). Replacement if you edit an existing `AttributeDefinition`.

`GlobalSecondaryIndexes`

Global secondary indexes to be created on the table. You can create up to 5 global secondary indexes.

> **Important**
> If you update a table to include a new global secondary index, AWS CloudFormation initiates the index creation and then proceeds with the stack update. AWS CloudFormation doesn't wait for the index to complete creation because the backfilling phase can take a long time, depending on the size of the table. You can't use the index or update the table until the index's status is `ACTIVE`. You can track its status by using the DynamoDB `DescribeTable` command.
> If you add or delete an index during an update, we recommend that you don't update any other resources. If your stack fails to update and is rolled back while adding a new index, you must manually delete the index.

Required: No

Type: List of GlobalSecondaryIndex (p. 1128)

Update requires: Updates are not supported. The following are exceptions:

- If you update only the provisioned throughput values of global secondary indexes, you can update the table without interruption (p. 120).
- You can delete or add one global secondary index without interruption (p. 120). If you do both in the same update (for example, by changing the index's logical ID), the update fails.

`KeySchema`

Specifies the attributes that make up the primary key for the table. The attributes in the `KeySchema` property must also be defined in the `AttributeDefinitions` property.

Required: Yes

Type: List of KeySchema (p. 1129)

Update requires: Replacement (p. 121)

`LocalSecondaryIndexes`

Local secondary indexes to be created on the table. You can create up to 5 local secondary indexes. Each index is scoped to a given hash key value. The size of each hash key can be up to 10 gigabytes.

Required: No

Type: List of LocalSecondaryIndex (p. 1130)

Update requires: Replacement (p. 121)

`PointInTimeRecoverySpecification`

The settings used to enable point in time recovery.

Required: No

Type: PointInTimeRecoverySpecification (p. 1131)

Update requires: No interruption (p. 120)

`ProvisionedThroughput`

Throughput for the specified table, which consists of values for `ReadCapacityUnits` and `WriteCapacityUnits`. For more information about the contents of a provisioned throughput structure, see Amazon DynamoDB Table ProvisionedThroughput (p. 1133).

Required: Yes

Type: ProvisionedThroughput (p. 1133)

Update requires: No interruption (p. 120)

`SSESpecification`

Specifies the settings to enable server-side encryption.

Required: No

Type: DynamoDB Table SSESpecification (p. 1134)

Update requires: Some interruptions (p. 121)

`StreamSpecification`

The settings for the DynamoDB table stream, which capture changes to items stored in the table.

Required: No

Type: StreamSpecification (p. 1134)

Update requires: No interruption (p. 120) to the table. However, the stream is replaced.

`TableName`

A name for the table. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the table name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this table. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`TimeToLiveSpecification`

Specifies the Time to Live (TTL) settings for the table.

Required: No

Type: TimeToLiveSpecification (p. 1135)

Update requires: No interruption (p. 120)

> **Note**
> For detailed information about the limits in DynamoDB, see Limits in Amazon DynamoDB in the *Amazon DynamoDB Developer Guide*.

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyResource" }
```

For the resource with the logical ID `myDynamoDBTable`, `Ref` will return the DynamoDB table name.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The Amazon Resource Name (ARN) of the DynamoDB table, such as `arn:aws:dynamodb:us-east-2:123456789012:table/myDynamoDBTable`.

`StreamArn`

The ARN of the DynamoDB stream, such as `arn:aws:dynamodb:us-east-1:123456789012:table/testddbstack-myDynamoDBTable-012A1SL7SMP5Q/stream/2015-11-30T20:10:00.000`.

> **Note**
> You must specify the `StreamSpecification` property to use this attribute.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

DynamoDB Table with Local and Secondary Indexes

The following sample creates an DynamoDB table with `Album`, `Artist`, `Sales`, `NumberOfSongs` as attributes. The primary key includes the `Album` attribute as the hash key and `Artist` attribute as the range key. The table also includes two global and one secondary index. For querying the number of sales for a given artist, the global secondary index uses the `Sales` attribute as the hash key and the `Artist` attribute as the range key.

For querying the sales based on the number of songs, the global secondary index uses the `NumberOfSongs` attribute as the hash key and the `Sales` attribute as the range key.

For querying the sales of an album, the local secondary index uses the same hash key as the table but uses the `Sales` attribute as the range key.

JSON

```
{
  "AWSTemplateFormatVersion" : "2010-09-09",
  "Resources" : {
    "myDynamoDBTable" : {

              - "NumberOfSongs"
            ProjectionType: "INCLUDE"
```

DynamoDB Table with a DependsOn Attribute

If you include multiple DynamoDB tables with indexes in a single template, you must include dependencies so that the tables are created sequentially. DynamoDB limits the number of tables with secondary indexes that are in the creating state. If you create multiple tables with indexes at the same time, DynamoDB returns an error and the stack operation fails.

The following sample assumes that the `myFirstDDBTable` table is declared in the same template as the `mySecondDDBTable` table, and both tables include a secondary index. The `mySecondDDBTable` table includes a dependency on the `myFirstDDBTable` table so that AWS CloudFormation creates the tables one at a time.

JSON

```
"mySecondDDBTable" : {
  "Type" : "AWS::DynamoDB::Table",
  "DependsOn" : "myFirstDDBTable" ,
  "Properties" : {
    "AttributeDefinitions" : [
      {
        "AttributeName" : "ArtistId",
        "AttributeType" : "S"
      },
      {
        "AttributeName" : "Concert",
        "AttributeType" : "S"
      },
      {
        "AttributeName" : "TicketSales",
        "AttributeType" : "S"
      }
    ],
    "KeySchema" : [
      {
        "AttributeName" : "ArtistId",
        "KeyType" : "HASH"
```

```
      },
      {
        "AttributeName" : "Concert",
        "KeyType" : "RANGE"
      }
    ],
    "ProvisionedThroughput" : {
      "ReadCapacityUnits" : {"Ref" : "ReadCapacityUnits"},
      "WriteCapacityUnits" : {"Ref" : "WriteCapacityUnits"}
    },
    "GlobalSecondaryIndexes" : [{
      "IndexName" : "myGSI",
      "KeySchema" : [
        {
          "AttributeName" : "TicketSales",
          "KeyType" : "HASH"
        }
      ],
      "Projection" : {
        "ProjectionType" : "KEYS_ONLY"
      },
      "ProvisionedThroughput" : {
        "ReadCapacityUnits" : {"Ref" : "ReadCapacityUnits"},
        "WriteCapacityUnits" : {"Ref" : "WriteCapacityUnits"}
      }
    }],
    "Tags": [
      {
        "Key": "foo",
        "Value": "bar"
      }
    ]
  }
}
```

YAML

```
mySecondDDBTable:
  Type: AWS::DynamoDB::Table
  DependsOn: "myFirstDDBTable"
  Properties:
    AttributeDefinitions:
      -
        AttributeName: "ArtistId"
        AttributeType: "S"
      -
        AttributeName: "Concert"
        AttributeType: "S"
      -
        AttributeName: "TicketSales"
        AttributeType: "S"
    KeySchema:
      -
        AttributeName: "ArtistId"
        KeyType: "HASH"
      -
        AttributeName: "Concert"
        KeyType: "RANGE"
    ProvisionedThroughput:
      ReadCapacityUnits:
        Ref: "ReadCapacityUnits"
      WriteCapacityUnits:
        Ref: "WriteCapacityUnits"
    GlobalSecondaryIndexes:
```

```
      -
        IndexName: "myGSI"
        KeySchema:
          -
            AttributeName: "TicketSales"
            KeyType: "HASH"
        Projection:
          ProjectionType: "KEYS_ONLY"
        ProvisionedThroughput:
          ReadCapacityUnits:
            Ref: "ReadCapacityUnits"
          WriteCapacityUnits:
            Ref: "WriteCapacityUnits"
    Tags:
      - Key: foo
        Value: bar
```

DynamoDB Table with Application Auto Scaling

This example sets up Application Auto Scaling for a `AWS::DynamoDB::Table` resource. The template defines a `TargetTrackingScaling` scaling policy that scales up the `WriteCapacityUnits` throughput for the table.

JSON

```
{
  "Resources": {
    "DDBTable": {
      "Type": "AWS::DynamoDB::Table",
      "Properties": {
        "AttributeDefinitions": [
          {
            "AttributeName": "ArtistId",
            "AttributeType": "S"
          },
          {
            "AttributeName": "Concert",
            "AttributeType": "S"
          },
          {
            "AttributeName": "TicketSales",

Amazon DynamoDB Table AttributeDefinition

The `AttributeDefinition` property type represents an attribute for describing the key schema for a DynamoDB table and indexes.

> **Note**
> AWS CloudFormation uses these attributes to provision the keys for the table. They don't represent the full schema of the table.

The `AttributeDefinition` property of the AWS::DynamoDB::Table (p. 1115) resource contains a list of `AttributeDefinition` property types.

Syntax

JSON

```
{
  "AttributeName" : String,
  "AttributeType" : String
}
```

YAML

```
AttributeName: String
AttributeType: String
```

Properties

`AttributeName`

The name of an attribute. Attribute names can be 1 – 255 characters long and have no character restrictions.

Required: Yes

Type: String

`AttributeType`

The data type for the attribute. You can specify `S` for string data, `N` for numeric data, or `B` for binary data.

Required: Yes

Type: String

Amazon DynamoDB Table GlobalSecondaryIndex

Describes global secondary indexes for the AWS::DynamoDB::Table (p. 1115) resource.

Syntax

JSON

```
{
  "IndexName" : String,
  "KeySchema" : [ KeySchema, ... ],
  "Projection" : { Projection },
  "ProvisionedThroughput" : { ProvisionedThroughput }
```

```
}
```

YAML

```
IndexName: String
KeySchema:
  - KeySchema
Projection:
  Projection
ProvisionedThroughput:
  ProvisionedThroughput
```

Properties

`IndexName`

The name of the global secondary index. The index name can be 3 – 255 characters long and must satisfy the regular expression pattern `[a-zA-Z0-9_.-]+`.

Required: Yes

Type: String

`KeySchema`

The complete index key schema for the global secondary index, which consists of one or more pairs of attribute names and key types.

Required: Yes

Type: List of KeySchema (p. 1129)

`Projection`

Attributes that are copied (projected) from the source table into the index. These attributes are in addition to the primary key attributes and index key attributes, which are automatically projected.

Required: Yes

Type: Projection (p. 1132)

`ProvisionedThroughput`

The provisioned throughput settings for the index.

Required: Yes

Type: ProvisionedThroughput (p. 1133)

Amazon DynamoDB Table KeySchema

Describes a primary key for the AWS::DynamoDB::Table (p. 1115) resource or a key schema for an index. Each element is composed of an `AttributeName` and `KeyType`.

For the primary key of an Amazon DynamoDB table that consists of only a hash attribute, specify one element with a `KeyType` of `HASH`. For the primary key of an Amazon DynamoDB table that consists of a hash and range attributes, specify two elements: one with a `KeyType` of `HASH` and one with a `KeyType` of `RANGE`.

For a complete discussion of DynamoDB primary keys, see Primary Key in the *Amazon DynamoDB Developer Guide*.

Syntax

JSON

```
{
  "AttributeName" : String,
  "KeyType" : "HASH or RANGE"
}
```

YAML

```
AttributeName: String
KeyType: HASH or RANGE
```

Properties

`AttributeName`

The attribute name that is used as the primary key for this table. Primary key element names can be 1 – 255 characters long and have no character restrictions.

Required: Yes

Type: String

`KeyType`

Represents the attribute data, consisting of the data type and the attribute value itself. You can specify `HASH` or `RANGE`.

Required: Yes

Type: String

Examples

For an example of a declared key schema, see AWS::DynamoDB::Table (p. 1115).

Amazon DynamoDB Table LocalSecondaryIndex

Describes local secondary indexes for the AWS::DynamoDB::Table (p. 1115) resource. Each index is scoped to a given hash key value. Tables with one or more local secondary indexes are subject to an item collection size limit, where the amount of data within a given item collection cannot exceed 10 GB.

Syntax

JSON

```
{
  "IndexName" : String,
  "KeySchema" : [ KeySchema, ...],
  "Projection" : { Projection }
}
```

YAML

```
IndexName: String
KeySchema:
```

```
  KeySchema
Projection:
  Projection
```

Properties

`IndexName`

The name of the local secondary index. The index name can be 3 – 255 characters long and have no character restrictions.

Required: Yes

Type: String

`KeySchema`

The complete index key schema for the local secondary index, which consists of one or more pairs of attribute names and key types. For local secondary indexes, the hash key must be the same as that of the source table.

Required: Yes

Type: List of KeySchema (p. 1129)

`Projection`

Attributes that are copied (projected) from the source table into the index. These attributes are additions to the primary key attributes and index key attributes, which are automatically projected.

Required: Yes

Type: Projection (p. 1132)

Examples

For an example of a declared local secondary index, see AWS::DynamoDB::Table (p. 1115).

DynamoDB Table PointInTimeRecoverySpecification

The `PointInTimeRecoverySpecification` property type enables point in time recovery in a DynamoDB table.

`PointInTimeRecoverySpecification` is a property of the AWS::DynamoDB::Table (p. 1115) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "PointInTimeRecoveryEnabled" : Boolean
}
```

YAML

```
PointInTimeRecoveryEnabled: Boolean
```

Properties

`PointInTimeRecoveryEnabled`

Indicates whether point in time recovery is enabled (true) or disabled (false) on the table.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

See Also

- PointInTimeRecoverySpecification in the *Amazon DynamoDB API Reference*

Amazon DynamoDB Table Projection

Attributes that are copied (projected) from the source table into the index. These attributes are additions to the primary key attributes and index key attributes, which are automatically projected.

Projection is a property of the GlobalSecondaryIndex (p. 1128) and LocalSecondaryIndex (p. 1130) property types.

Syntax

JSON

```
{
  "NonKeyAttributes" : [ String, ... ],
  "ProjectionType" : String
}
```

YAML

```
NonKeyAttributes:
  - String
ProjectionType: String
```

Properties

For more information about each property, including constraints, see Projection in the *Amazon DynamoDB API Reference*.

`NonKeyAttributes`

The non-key attribute names that are projected into the index.

For local secondary indexes, the total count of `NonKeyAttributes` summed across all of the local secondary indexes must not exceed 20. If you project the same attribute into two different indexes, this counts as two distinct attributes in determining the total. This limit does not apply for secondary indexes with a ProjectionType of `KEYS_ONLY` or `ALL`.

Required: No

Type: List of String values

`ProjectionType`

The set of attributes that are projected into the index:

`KEYS_ONLY`

Only the index and primary keys are projected into the index.

`INCLUDE`

Only the specified table attributes are projected into the index. The list of projected attributes are in `NonKeyAttributes`.

`ALL`

All of the table attributes are projected into the index.

Required: Yes

Type: String

Amazon DynamoDB Table ProvisionedThroughput

Describes a set of provisioned throughput values for an AWS::DynamoDB::Table (p. 1115) resource. DynamoDB uses these capacity units to allocate sufficient resources to provide the requested throughput.

For a complete discussion of DynamoDB provisioned throughput values, see Specifying Read and Write Requirements in the *DynamoDB Developer Guide*.

Syntax

JSON

```
{
   "ReadCapacityUnits (p. 1133)" : Number,
   "WriteCapacityUnits (p. 1133)" : Number
}
```

YAML

```
ReadCapacityUnits (p. 1133): Number
WriteCapacityUnits (p. 1133): Number
```

Parameters

`ReadCapacityUnits`

Sets the desired minimum number of consistent reads of items (up to 1KB in size) per second for the specified table before Amazon DynamoDB balances the load.

Required: Yes

Type: Number

`WriteCapacityUnits`

Sets the desired minimum number of consistent writes of items (up to 1KB in size) per second for the specified table before Amazon DynamoDB balances the load.

Required: Yes

Type: Number

Note
For detailed information about the limits of provisioned throughput values in DynamoDB, see Limits in Amazon DynamoDB in the *DynamoDB Developer Guide*.

DynamoDB Table SSESpecification

The `SSESpecification` property is part of the AWS::DynamoDB::Table (p. 1115) resource that specifies the settings to enable server-side encryption.

If you do not specify the `SSESpecification` property type, Amazon DynamoDB will create an unencrypted table, the same as if you had specified the `SSESpecification` property type with its `SSEEnabled` property set to `false`. As a best practice, for consistency only specify the `SSESpecification` property type (with its `SSEEnabled` property set to `true`) if you want DynamoDB to create an encrypted table.

Syntax

JSON

```
{
  "SSEEnabled" : Boolean
}
```

YAML

```
SSEEnabled: Boolean
```

Properties

`SSEEnabled`

Whether server-side encryption is enabled or not.

Required: Yes

Type: Boolean

Update requires: Replacement (p. 121)

Amazon DynamoDB Table StreamSpecification

`StreamSpecification` is a property of the AWS::DynamoDB::Table (p. 1115) resource that defines the settings of a DynamoDB table's stream.

Syntax

JSON

```
{
   "StreamViewType" : String
}
```

YAML

```
StreamViewType: String
```

Parameters

`StreamViewType`

Determines the information that the stream captures when an item in the table is modified. For valid values, see StreamSpecification in the *Amazon DynamoDB API Reference*.

Required: Yes

Type: String

Amazon DynamoDB Table TimeToLiveSpecification

The `TimeToLiveSpecification` property specifies the Time to Live (TTL) settings for an AWS::DynamoDB::Table (p. 1115) resource. It is expressed as an attribute on the items in the table. For more information, see UpdateTimeToLive in the *Amazon DynamoDB API Reference*.

Syntax

JSON

```
{
  "AttributeName" : String,
  "Enabled" : Boolean
}
```

YAML

```
AttributeName: String
Enabled: Boolean
```

Properties

`AttributeName`

The name of the TTL attribute that stores the expiration time for items in the table. The name can be 1–255 characters long, and has no character restrictions.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Enabled`

Indicates whether to enable (by specifying `true`) or disable (by specifying `false`) TTL on the table.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

Amazon EC2 Resource Types Reference

This section contains reference information for all Amazon EC2 resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::EC2::data-type-name
```

AWS::EC2::CustomerGateway

Provides information to AWS about your VPN customer gateway device.

Topics

- Syntax (p. 1137)
- Properties (p. 1137)
- Return Value (p. 1138)
- Example (p. 1138)
- See Also (p. 1139)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::CustomerGateway",
   "Properties" : {
      "BgpAsn (p. 1137)" : Number,
      "IpAddress (p. 1138)" : String,
      "Tags" :  [ Resource Tag, ... ],
      "Type (p. 1138)" : String
   }
}
```

YAML

```
Type: AWS::EC2::CustomerGateway
Properties:
  BgpAsn (p. 1137): Number
  IpAddress (p. 1138): String
  Tags:
    Resource Tag
  Type (p. 1138): String
```

Properties

`BgpAsn`

The customer gateway's Border Gateway Protocol (BGP) Autonomous System Number (ASN).

Required: Yes

Type: Number BgpAsn is always an integer value.

Update requires: Replacement (p. 121)

`IpAddress`

The internet-routable IP address for the customer gateway's outside interface. The address must be static.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

The tags that you want to attach to the resource.

Required: No

Type: Resource Tag (p. 2258).

Update requires: No interruption (p. 120).

`Type`

The type of VPN connection that this customer gateway supports.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Example: `ipsec.1`

Return Value

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyResource" }
```

For the resource with the logical ID "MyResource", `Ref` will return the AWS resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myCustomerGateway" : {
         "Type" : "AWS::EC2::CustomerGateway",
         "Properties" : {
            "Type" : "ipsec.1",
            "BgpAsn" : "64000",
            "IpAddress" : "1.1.1.1"
         }
```

```
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  myCustomerGateway:
    Type: AWS::EC2::CustomerGateway
    Properties:
      Type: ipsec.1
      BgpAsn: 64000
      IpAddress: 1.1.1.1
```

See Also

- CreateCustomerGateway in the *Amazon EC2 API Reference*.

AWS::EC2::DHCPOptions

Creates a set of DHCP options for your VPC.

For more information, see CreateDhcpOptions in the *Amazon EC2 API Reference*.

Topics

- Syntax (p. 1139)
- Properties (p. 1140)
- Conditional Properties (p. 1141)
- Return Values (p. 1141)
- Example (p. 1142)
- See Also (p. 1142)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::DHCPOptions",
   "Properties" : {
      "DomainName (p. 1140)" : String,
      "DomainNameServers (p. 1140)" : [ String, ... ],
      "NetbiosNameServers (p. 1140)" : [ String, ... ],
      "NetbiosNodeType (p. 1140)" : Number,
      "NtpServers (p. 1141)" : [ String, ... ],
      "Tags (p. 1141)" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::EC2::DHCPOptions
Properties:
  DomainName (p. 1140): String
  DomainNameServers (p. 1140):
    - String
  NetbiosNameServers (p. 1140):
    - String
  NetbiosNodeType (p. 1140): Number
  NtpServers (p. 1141):
    - String
  Tags (p. 1141):
    -Resource Tag
```

Properties

`DomainName`

A domain name of your choice.

Required: Conditional; see note (p. 1141).

Type: String

Update requires: Replacement (p. 121)

Example: `"example.com"`

`DomainNameServers`

The IP (IPv4) address of a domain name server. You can specify up to four addresses.

Required: Conditional; see note (p. 1141).

Type: List of String values

Update requires: Replacement (p. 121)

Example: `"DomainNameServers" : [ "10.0.0.1", "10.0.0.2" ]`

Example: To preserve the order of IP addresses, specify a comma delimited list as a single string: `"DomainNameServers" : [ "10.0.0.1, 10.0.0.2" ]`

`NetbiosNameServers`

The IP address (IPv4) of a NetBIOS name server. You can specify up to four addresses.

Required: Conditional; see note (p. 1141).

Type: List of String values

Update requires: Replacement (p. 121)

Example: `"NetbiosNameServers" : [ "10.0.0.1", "10.0.0.2" ]`

Example: To preserve the order of IP addresses, specify a comma delimited list as a single string: `"NetbiosNameServers" : [ "10.0.0.1, 10.0.0.2" ]`

`NetbiosNodeType`

An integer value indicating the NetBIOS node type:

- **1**: Broadcast ("B")
- **2**: Point-to-point ("P")
- **4**: Mixed mode ("M")

- **8**: Hybrid ("H")

For more information about these values and about NetBIOS node types, see RFC 2132, RFC 1001, and RFC 1002. We recommend that you use only the value `2` at this time (broadcast and multicast are not currently supported).

Required: Required if `NetBiosNameServers` is specified; optional otherwise.

Type: List of numbers

Update requires: Replacement (p. 121)

Example: `"NetbiosNodeType" : 2`

`NtpServers`

The IP address (IPv4) of a Network Time Protocol (NTP) server. You can specify up to four addresses.

Required: Conditional; see note (p. 1141).

Type: List of String values

Update requires: Replacement (p. 121)

Example: `"NtpServers" : [ "10.0.0.1" ]`

Example: To preserve the order of IP addresses, specify a comma delimited list as a single string: `"NtpServers" : [ "10.0.0.1, 10.0.0.2" ]`

`Tags`

An arbitrary set of tags (key–value pairs) for this resource.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

Conditional Properties

At least one of the following properties must be specified:

- DomainNameServers (p. 1140)
- NetbiosNameServers (p. 1140)
- NtpServers (p. 1141)

After this condition has been fulfilled, the rest of these properties are optional.

If you specify `NetbiosNameServers`, then `NetbiosNodeType` is required.

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myDhcpOptions" : {
         "Type" : "AWS::EC2::DHCPOptions",
         "Properties" : {
            "DomainName" : "example.com",
            "DomainNameServers" : [ "AmazonProvidedDNS" ],
            "NtpServers" : [ "10.2.5.1" ],
            "NetbiosNameServers" : [ "10.2.5.1" ],
            "NetbiosNodeType" : 2,
            "Tags" : [ { "Key" : "foo", "Value" : "bar" } ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  myDhcpOptions:
    Type: AWS::EC2::DHCPOptions
    Properties:
      DomainName: example.com
      DomainNameServers:
        - AmazonProvidedDNS
      NtpServers:
        - 10.2.5.1
      NetbiosNameServers:
        - 10.2.5.1
      NetbiosNodeType: 2
      Tags:
        -
          Key: foo
          Value: bar
```

AWS::EC2::EgressOnlyInternetGateway

The `AWS::EC2::EgressOnlyInternetGateway` resource creates an egress-only Internet gateway for your VPC (over IPv6 only). An egress-only Internet gateway enables outbound communication over IPv6 from instances in your VPC to the Internet. It also prevents hosts outside of your VPC from initiating an IPv6 connection with your instance.

Topics

- Syntax (p. 1143)
- Properties (p. 1143)
- Return Values (p. 1143)
- Example (p. 1143)
- More Info (p. 1144)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type": "AWS::EC2::EgressOnlyInternetGateway",
  "Properties": {
    "VpcId": String
  }
}
```

YAML

```
Type: AWS::EC2::EgressOnlyInternetGateway
Properties:
  VpcId: String
```

Properties

`VpcId`

The ID of the VPC for which to create the egress-only Internet gateway.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the ID of the egress-only Internet gateway (the physical resource ID).

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates an egress-only Internet gateway for the specified VPC.

JSON

```
{
```

```
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
    "myEgressOnlyInternetGateway": {
      "Type": "AWS::EC2::EgressOnlyInternetGateway",
      "Properties": {
        "VpcId": "vpc-1a2b3c4d"
      }
    }
  }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  myEgressOnlyInternetGateway:
    Type: AWS::EC2::EgressOnlyInternetGateway
    Properties:
      VpcId: vpc-1a2b3c4d
```

More Info

- CreateEgressOnlyInternetGateway in the *Amazon EC2 API Reference*.

AWS::EC2::EIP

The AWS::EC2::EIP resource allocates an Elastic IP (EIP) address and can, optionally, associate it with an Amazon EC2 instance.

Topics

- Syntax (p. 1144)
- Properties (p. 1145)
- Return Values (p. 1145)
- Examples (p. 1145)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::EIP",
   "Properties" : {
      "InstanceId (p. 1145)" : String,
      "Domain (p. 1145)" : String
   }
}
```

YAML

```
Type: AWS::EC2::EIP
Properties:
  InstanceId (p. 1145): String
```

```
  Domain (p. 1145): String
```

Properties

`InstanceId`

The Instance ID of the Amazon EC2 instance that you want to associate with this Elastic IP address.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Domain`

Set to `vpc` to allocate the address to your Virtual Private Cloud (VPC). No other values are supported.

> **Note**
> If you define an Elastic IP address and associate it with a VPC that is defined in the same template, you must declare a dependency on the VPC-gateway attachment by using the `DependsOn` attribute on this resource. For more information, see DependsOn Attribute (p. 2275).

For more information, see AllocateAddress in the *Amazon EC2 API Reference*. For more information about Elastic IP Addresses in VPC, go to IP Addressing in Your VPC in the *Amazon VPC User Guide*.

Required: Conditional. Required when allocating an address to a VPC

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you specify the logical ID of an AWS::EC2::EIP object as an argument to the `Ref` function, AWS CloudFormation returns the value of the instance's `PublicIp`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`AllocationId`

The ID that AWS assigns to represent the allocation of the address for use with Amazon VPC. This is returned only for VPC elastic IP addresses. Example return value: `eipalloc-5723d13e`

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

To view AWS::EC2::EIP snippets, see Assigning an Amazon EC2 Elastic IP Using AWS::EC2::EIP Snippet (p. 344).

AWS::EC2::EIPAssociation

The AWS::EC2::EIPAssociation resource type associates an Elastic IP address with an Amazon EC2 instance. The Elastic IP address can be an existing Elastic IP address or an Elastic IP address allocated through an AWS::EC2::EIP resource (p. 1144).

For more information EC2-Classic and EC2-VPC, see AssociateAddress in the *Amazon EC2 API Reference*.

Topics

- Syntax (p. 1146)
- Properties (p. 1146)
- Return Values (p. 1147)
- Examples (p. 1148)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type": "AWS::EC2::EIPAssociation",
   "Properties": {
      "AllocationId (p. 1146)": String,
      "EIP (p. 1147)": String,
      "InstanceId (p. 1147)": String,
      "NetworkInterfaceId (p. 1147)": String,
      "PrivateIpAddress (p. 1147)": String
   }
}
```

YAML

```
Type: AWS::EC2::EIPAssociation
Properties:
  AllocationId (p. 1146): String
  EIP (p. 1147): String
  InstanceId (p. 1147): String
  NetworkInterfaceId (p. 1147): String
  PrivateIpAddress (p. 1147): String
```

Properties

`AllocationId`

[EC2-VPC] Allocation ID for the VPC Elastic IP address you want to associate with an Amazon EC2 instance in your VPC.

Required: Conditional. Required for EC2-VPC.

Type: String

Update requires: Replacement (p. 121) if you also change the `InstanceId` or `NetworkInterfaceId` property. If not, update requires No interruption (p. 120).

`EIP`

Elastic IP address that you want to associate with the Amazon EC2 instance specified by the `InstanceId` property. You can specify an existing Elastic IP address or a reference to an Elastic IP address allocated with a AWS::EC2::EIP resource (p. 1144).

Required: Conditional. Required for EC2-Classic.

Type: String

Update requires: Replacement (p. 121) if you also change the `InstanceId` or `NetworkInterfaceId` property. If not, update requires No interruption (p. 120).

`InstanceId`

Instance ID of the Amazon EC2 instance that you want to associate with the Elastic IP address specified by the EIP property. If the instance has more than one network interface, you must specify a network interface ID.

Required: Conditional. If you specify the `EIP` property, you must specify this property. If you specify the `AllocationId` property, you must specify this property or the `NetworkInterfaceId` property.

Type: String

Update requires: Replacement (p. 121) if you also change the `AllocationId` or `EIP` property. If not, update requires No interruption (p. 120).

`NetworkInterfaceId`

[EC2-VPC] The ID of the network interface to associate with the Elastic IP address. If the instance has more than one network interface, you must specify a network interface ID.

Required: Conditional. If you specify the `AllocationId` property, you must specify this property or the `InstanceId` property.

Type: String

Update requires: Replacement (p. 121) if you also change the `AllocationId` or `EIP` property. If not, update requires No interruption (p. 120).

`PrivateIpAddress`

[EC2-VPC] The private IP address that you want to associate with the Elastic IP address. The private IP address is restricted to the primary and secondary private IP addresses that are associated with the network interface. By default, the private IP address that is associated with the EIP is the primary private IP address of the network interface.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following example creates an instance with two elastic network interfaces (ENI). The example assumes that you have an existing VPC.

For additional examples, see Assigning an Amazon EC2 Elastic IP Using AWS::EC2::EIP Snippet (p. 344).

```

AWS::EC2::FlowLog

The `AWS::EC2::FlowLog` resource creates an Amazon Elastic Compute Cloud (Amazon EC2) flow log that captures IP traffic for a specified network interface, subnet, or VPC. To view the log data, use Amazon CloudWatch Logs (CloudWatch Logs) to help troubleshoot connection issues. For example, you can use a flow log to investigate why certain traffic isn't reaching an instance, which can help you diagnose overly restrictive security group rules. For more information, see VPC Flow Logs in the *Amazon VPC User Guide*.

Topics

- Syntax (p. 1151)
- Properties (p. 1151)
- Return Value (p. 1153)
- Example (p. 1153)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::FlowLog",
  "Properties" : {
    "DeliverLogsPermissionArn" : String,
    "LogDestination" : String,
    "LogDestinationType" : String,
    "LogGroupName" : String,
    "ResourceId" : String,
    "ResourceType" : String,
    "TrafficType" : String
  }
}
```

YAML

```
Type: AWS::EC2::FlowLog
Properties:
  DeliverLogsPermissionArn : String
  LogDestination : String
  LogDestinationType : String
  LogGroupName : String
  ResourceId : String
  ResourceType : String
  TrafficType : String
```

Properties

`DeliverLogsPermissionArn`

The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role that permits Amazon EC2 to publish flow logs to a CloudWatch Logs log group in your account.

If you specify `LogDestinationType` as `s3`, do not specify `DeliverLogsPermissionArn` or `LogGroupName`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`LogDestination`

Specifies the destination to which the flow log data is to be published. Flow log data can be published to a CloudWatch Logs log group or an Amazon S3 bucket. The value specified for this parameter depends on the value specified for `LogDestinationType`.

- If `LogDestinationType` is not specified or `cloud-watch-logs`, specify the Amazon Resource Name (ARN) of the CloudWatch Logs log group.
- If `LogDestinationType` is `s3`, specify the ARN of the Amazon S3 bucket. You can also specify a subfolder in the bucket. To specify a subfolder in the bucket, use the following ARN format: `bucket_ARN/subfolder_name/`. For example, to specify a subfolder named my-logs in a bucket named my-bucket , use the following ARN: `arn:aws:s3:::my-bucket/my-logs/`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`LogDestinationType`

Specifies the type of destination to which the flow log data is to be published. Flow log data can be published to CloudWatch Logs or Amazon S3. To publish flow log data to CloudWatch Logs, specify `cloud-watch-logs`. To publish flow log data to Amazon S3, specify `s3`.

If you specify `LogDestinationType` as `s3`, do not specify `DeliverLogsPermissionArn` or `LogGroupName`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`LogGroupName`

The name of a new or existing CloudWatch Logs log group where Amazon EC2 publishes your flow logs.

If you specify `LogDestinationType` as `s3`, do not specify `DeliverLogsPermissionArn` or `LogGroupName`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ResourceId`

The ID of the subnet, network interface, or VPC for which you want to create a flow log.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ResourceType`

The type of resource that you specified in the `ResourceId` property. For example, if you specified a VPC ID for the `ResourceId` property, specify `VPC` for this property. For valid values, see the `ResourceType` parameter for the CreateFlowLogs action in the *Amazon EC2 API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`TrafficType`

The type of traffic to log. You can log traffic that the resource accepts or rejects, or all traffic. For valid values, see the `TrafficType` parameter for the CreateFlowLogs action in the *Amazon EC2 API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the flow log ID, such as `fl-1a23b456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a flow log for the VPC called `MyVPC` and logs all traffic types. Amazon EC2 publishes the logs to the `FlowLogsGroup` log group.

```
"MyFlowLog" : {
  "Type" : "AWS::EC2::FlowLog",
  "Properties" : {
    "DeliverLogsPermissionArn" : { "Fn::GetAtt" : ["FlowLogRole", "Arn"] },
    "LogGroupName" : "FlowLogsGroup",
    "ResourceId" : { "Ref" : "MyVPC" },
    "ResourceType" : "VPC",
    "TrafficType" : "ALL"
  }
}
```

AWS::EC2::Host

The `AWS::EC2::Host` resource allocates a fully dedicated physical server for launching EC2 instances. Because the host is fully dedicated for your use, it can help you address compliance requirements and reduce costs by allowing you to use your existing server-bound software licenses. For more information, see Dedicated Hosts in the *Amazon EC2 User Guide for Linux Instances*.

Topics

- Syntax (p. 1153)
- Properties (p. 1154)
- Return Value (p. 1154)
- Example (p. 1155)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Type" : "AWS::EC2::Host",
  "Properties" : {
    "AutoPlacement" : String,
    "AvailabilityZone" : String,
    "InstanceType" : String
  }
}
```

YAML

```
Type: AWS::EC2::Host
Properties:
  AutoPlacement: String
  AvailabilityZone: String
  InstanceType: String
```

Properties

`AutoPlacement`

Indicates if the host accepts EC2 instances with only matching configurations or if instances must also specify the host ID. Instances that don't specify a host ID can't launch onto a host with `AutoPlacement` set to `off`. By default, AWS CloudFormation sets this property to `on`. For more information, see Understanding Instance Placement and Host Affinity in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`AvailabilityZone`

The Availability Zone (AZ) in which to launch the dedicated host.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`InstanceType`

The instance type that the dedicated host accepts. Only instances of this type can be launched onto the host. For more information, see Supported Instance Types in the *Amazon EC2 User Guide for Linux Instances*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the host ID, such as `h-0ab123c45d67ef89`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example allocates a dedicated host for `c3.large` instances in the `us-east-1a` Availability Zone.

```
"Host" : {
  "Type" : "AWS::EC2::Host",
  "Properties" : {
    "AutoPlacement" : "on",
    "AvailabilityZone" : "us-east-1a",
    "InstanceType" : "c3.large"
  }
}
```

AWS::EC2::Instance

The `AWS::EC2::Instance` resource creates an EC2 instance.

If an Elastic IP address is attached to your instance, AWS CloudFormation reattaches the Elastic IP address after it updates the instance. For more information about updating stacks, see AWS CloudFormation Stacks Updates (p. 120).

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::Instance",
   "Properties" : {
      "Affinity" : String,
      "AvailabilityZone" : String,
      "BlockDeviceMappings" : [ EC2 Block Device Mapping, ... ],
      "CreditSpecification" : CreditSpecification,
      "DisableApiTermination" : Boolean,
      "EbsOptimized" : Boolean,
      "ElasticGpuSpecifications" : [ ElasticGpuSpecification, ... ],
      "HostId" : String,
      "IamInstanceProfile" : String,
      "ImageId" : String,
      "InstanceInitiatedShutdownBehavior" : String,
      "InstanceType" : String,
      "Ipv6AddressCount" : Integer,
      "Ipv6Addresses" : [ IPv6 Address Type, ... ],
      "KernelId" : String,
      "KeyName" : String,
      "LaunchTemplate" : LaunchTemplateSpecification,
      "Monitoring" : Boolean,
      "NetworkInterfaces" : [ EC2 Network Interface, ... ],
      "PlacementGroupName" : String,
      "PrivateIpAddress" : String,
      "RamdiskId" : String,
      "SecurityGroupIds" : [ String, ... ],
      "SecurityGroups" : [ String, ... ],
      "SourceDestCheck" : Boolean,
      "SsmAssociations" : [ SSMAssociation, ... ],
      "SubnetId" : String,
      "Tags" : [ Resource Tag, ... ],
```

```
      "Tenancy" : String,
      "UserData" : String,
      "Volumes" : [ EC2 MountPoint (p. 1172), ... ],
      "AdditionalInfo" : String
   }
}
```

YAML

```
Type: AWS::EC2::Instance
Properties:
  Affinity: String
  AvailabilityZone: String
  BlockDeviceMappings:
    - EC2 Block Device Mapping
  CreditSpecification: CreditSpecification
  DisableApiTermination: Boolean
  EbsOptimized: Boolean
  ElasticGpuSpecifications: [ ElasticGpuSpecification, ... ]
  HostId: String
  IamInstanceProfile: String
  ImageId: String
  InstanceInitiatedShutdownBehavior: String
  InstanceType: String
  Ipv6AddressCount: Integer
  Ipv6Addresses:
    - IPv6 Address Type
  KernelId: String
  KeyName: String
  LaunchTemplate: LaunchTemplateSpecification
  Monitoring: Boolean
  NetworkInterfaces:
    - EC2 Network Interface
  PlacementGroupName: String
  PrivateIpAddress: String
  RamdiskId: String
  SecurityGroupIds:
    - String
  SecurityGroups:
    - String
  SourceDestCheck: Boolean
  SsmAssociations:
    - SSMAssociation
  SubnetId: String
  Tags:
    - Resource Tag
  Tenancy: String
  UserData: String
  Volumes:
    - EC2 MountPoint
  AdditionalInfo: String
```

Properties

`Affinity`

Indicates whether Amazon Elastic Compute Cloud (Amazon EC2) always associates the instance with a dedicated host (p. 1158). If you want Amazon EC2 to always restart the instance (if it was stopped) onto the same host on which it was launched, specify `host`. If you want Amazon EC2 to restart the instance on any available host, but to try to launch the instance onto the last host it ran on (on a best-effort basis), specify `default`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`AvailabilityZone`

Specifies the name of the Availability Zone in which the instance is located.

For more information about AWS regions and Availability Zones, see Regions and Availability Zones in the *Amazon EC2 User Guide*.

Required: No. If not specified, an Availability Zone will be automatically chosen for you based on the load balancing criteria for the region.

Type: String

Update requires: Replacement (p. 121)

`BlockDeviceMappings`

Defines a set of Amazon Elastic Block Store block device mappings, ephemeral instance store block device mappings, or both. For more information, see Amazon Elastic Block Store or Amazon EC2 Instance Store in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: A list of Amazon EC2 BlockDeviceMapping (p. 1166).

Update requires: Replacement (p. 121). If you change only the `DeleteOnTermination` property for one or more block devices, update requires No interruption (p. 120).

`CreditSpecification`

Specifies the credit option for CPU usage of a T2 instance.

Required: No

Type: Amazon EC2 Instance CreditSpecification (p. 1170).

Update requires: No interruption (p. 120)

`DisableApiTermination`

Specifies whether the instance can be terminated through the API.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`EbsOptimized`

Specifies whether the instance is optimized for Amazon Elastic Block Store I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal `EBS` I/O performance.

For more information about the instance types that can be launched as Amazon EBS optimized instances, see Amazon EBS-Optimized Instances in the *Amazon Elastic Compute Cloud User Guide*. Additional fees are incurred when using Amazon EBS-optimized instances.

Required: No. By default, AWS CloudFormation specifies `false`.

Type: Boolean

Update requires:

- *Update requires*: Some interruptions (p. 121) for Amazon EBS-backed instances
- *Update requires*: Replacement (p. 121) for instance store-backed instances

`ElasticGpuSpecifications`

Specifies the Elastic GPUs. An Elastic GPU is a GPU resource that you can attach to your instance to accelerate the graphics performance of your applications. For more information, see Amazon EC2 Elastic GPUs in the *Amazon EC2 User Guide for Windows Instances*. Duplicates are not allowed.

Required: No

Type: List of Amazon EC2 Instance ElasticGpuSpecification (p. 1170)

Update requires: Replacement (p. 121)

`HostId`

If you specify `host` for the `Affinity` property, the ID of a dedicated host that the instance is associated with. If you don't specify an ID, Amazon EC2 launches the instance onto any available, compatible dedicated host in your account. This type of launch is called an untargeted launch. Note that for untargeted launches, you must have a compatible, dedicated host available to successfully launch instances.

Required: No

Type: String

Update requires: No interruption (p. 120)

`IamInstanceProfile`

The name of an instance profile or a reference to an AWS::IAM::InstanceProfile (p. 1660) resource.

For more information about IAM roles, see Working with Roles in the *AWS Identity and Access Management User Guide*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ImageId`

Provides the unique ID of the Amazon Machine Image (AMI) that was assigned during registration.

Required: No

Type: String

Update requires: Replacement (p. 121)

`InstanceInitiatedShutdownBehavior`

Indicates whether an instance stops or terminates when you shut down the instance from the instance's operating system shutdown command. You can specify `stop` or `terminate`. For more information, see the RunInstances command in the *Amazon EC2 API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`InstanceType`

The instance type, such as `t2.micro`. The default type is `m1.small`. For a list of instance types, see Instance Families and Types.

Required: No

Type: String

Update requires:

- *Update requires*: Some interruptions (p. 121) for Amazon EBS-backed instances
- *Update requires*: Replacement (p. 121) for instance store-backed instances

`Ipv6AddressCount`

The number of IPv6 addresses to associate with the instance's primary network interface. Amazon EC2 automatically selects the IPv6 addresses from the subnet range. To specify specific IPv6 addresses, use the `Ipv6Addresses` property and don't specify this property.

For restrictions on which instance types support IPv6 addresses, see the RunInstances action in the *Amazon EC2 API Reference*.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`Ipv6Addresses`

One or more specific IPv6 addresses from the IPv6 CIDR block range of your subnet to associate with the instance's primary network interface. To specify a number of IPv6 addresses, use the `Ipv6AddressCount` property and don't specify this property.

For information about restrictions on which instance types support IPv6 addresses, see the RunInstances action in the *Amazon EC2 API Reference*.

Required: No

Type: List of EC2 NetworkInterface Ipv6Addresses (p. 1213)

Update requires: Replacement (p. 121)

`KernelId`

The kernel ID.

Required: No

Type: String

Update requires:

- *Update requires*: Some interruptions (p. 121) for Amazon EBS-backed instances
- *Update requires*: Replacement (p. 121) for instance store-backed instances

`KeyName`

Provides the name of the Amazon EC2 key pair.

Required: No

Type: String

Update requires: Replacement (p. 121)

`LaunchTemplate`

The launch template to use.

Required: No

Type: Amazon EC2 Instance LaunchTemplateSpecification (p. 1171)

Update requires: Replacement (p. 121)

`Monitoring`

Specifies whether detailed monitoring is enabled for the instance.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`NetworkInterfaces`

A list of embedded objects that describes the network interfaces to associate with this instance.

> **Note**
> If you use this property to point to a network interface, you must terminate the original interface before attaching a new one to allow the update of the instance to succeed.
> If this resource has a public IP address and is also in a VPC that is defined in the same template, you must use the `DependsOn` attribute to declare a dependency on the VPC-gateway attachment. For more information, see DependsOn Attribute (p. 2275).

Required: No

Type: A list of EC2 NetworkInterface (p. 1173)

Update requires: Replacement (p. 121)

`PlacementGroupName`

The name of an existing placement group that you want to launch the instance into (for cluster instances).

Required: No

Type: String

Update requires: Replacement (p. 121)

`PrivateIpAddress`

The private IP address for this instance.

> **Important**
> If you make an update to an instance that requires replacement, you must assign a new private IP address. During a replacement, AWS CloudFormation creates a new instance but doesn't delete the old instance until the stack has successfully updated. If the stack update fails, AWS CloudFormation uses the old instance in order to roll back the stack to

the previous working state. The old and new instances cannot have the same private IP address.

(Optional) If you're using Amazon VPC, you can use this parameter to assign the instance a specific available IP address from the subnet (for example, 10.0.0.25). By default, Amazon VPC selects an IP address from the subnet for the instance.

Required: No

Type: String

Update requires: Replacement (p. 121)

`RamdiskId`

The ID of the RAM disk to select. Some kernels require additional drivers at launch. Check the kernel requirements for information about whether you need to specify a RAM disk. To find kernel requirements, go to the AWS Resource Center and search for the kernel ID.

Required: No

Type: String

Update requires:

- *Update requires*: Some interruptions (p. 121) for Amazon EBS-backed instances
- *Update requires*: Replacement (p. 121) for instance store-backed instances

`SecurityGroupIds`

A list that contains the security group IDs for VPC security groups to assign to the Amazon EC2 instance. If you specified the `NetworkInterfaces` property, do not specify this property.

Required: Conditional. Required for VPC security groups.

Type: List of String values

Update requires:

- *Update requires*: No interruption (p. 120) for instances that are in a VPC.
- *Update requires*: Replacement (p. 121) for instances that are not in a VPC.

`SecurityGroups`

Valid only for Amazon EC2 security groups. A list that contains the Amazon EC2 security groups to assign to the Amazon EC2 instance. The list can contain both the name of existing Amazon EC2 security groups or references to AWS::EC2::SecurityGroup resources created in the template.

Required: No

Type: List of String values

Update requires: Replacement (p. 121).

`SourceDestCheck`

Controls whether source/destination checking is enabled on the instance. Also determines if an instance in a VPC will perform network address translation (NAT).

A value of `"true"` means that source/destination checking is enabled, and a value of `"false"` means that checking is disabled. For the instance to perform NAT, the value *must* be `"false"`. For more information, see NAT Instances in the *Amazon Virtual Private Cloud User Guide*.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`SsmAssociations`

The SSM document (p. 2152) and parameter values in AWS Systems Manager to associate with this instance. To use this property, you must specify an IAM instance profile role for the instance. For more information, see Create an Instance Profile for Systems Manager in the *AWS Systems Manager User Guide*.

Note
You can currently associate only one document with an instance.

Required: No

Type: List of Amazon EC2 Instance SsmAssociations (p. 1176).

Update requires: No interruption (p. 120)

`SubnetId`

If you're using Amazon VPC, this property specifies the ID of the subnet that you want to launch the instance into. If you specified the `NetworkInterfaces` property, do not specify this property.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) for this instance.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

`Tenancy`

The tenancy of the instance that you want to launch, such as `default`, `dedicated`, or `host`. If you specify a tenancy value of `dedicated` or `host`, you must launch the instance in a VPC. For more information, see Dedicated Instances in the *Amazon VPC User Guide*.

Required: No

Type: String

Update requires:

- *Update requires*: No interruption (p. 120) if this property was set to `dedicated` and you change it to `host` or vice versa.
- *Update requires*: Replacement (p. 121) for all other changes.

`UserData`

Base64-encoded MIME user data that is made available to the instances.

Required: No

Type: String

Update requires:

- *Update requires*: Some interruptions (p. 121) for Amazon EBS-backed instances.

  Note
  For EBS-backed instances, changing the `UserData` stops and then starts the instance; however, Amazon EC2 doesn't automatically run the updated `UserData`. To update configurations on your instance, use the cfn-hup (p. 2367) helper script.
- *Update requires*: Replacement (p. 121) for instance store-backed instances.

`Volumes`

The Amazon EBS volumes to attach to the instance.

Note
Before detaching a volume, unmount any file systems on the device within your operating system. If you don't unmount the file system, a volume might get stuck in a busy state while detaching.

Required: No

Type: A list of EC2 MountPoints (p. 1172).

Update requires: No interruption (p. 120)

`AdditionalInfo`

Reserved.

Required: No

Type: String

Update requires:

- *Update requires*: Some interruptions (p. 121) for Amazon EBS-backed instances
- *Update requires*: Replacement (p. 121) for instance store-backed instances

Return Values

Ref

When you pass the logical ID of an AWS::EC2::Instance object to the intrinsic `Ref` function, the object's InstanceId is returned. For example: `i-1234567890abcdef0`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`AvailabilityZone`

The Availability Zone where the specified instance is launched. For example: `us-east-1b`.

You can retrieve a list of all Availability Zones for a region by using the `Fn::GetAZs` (p. 2326) intrinsic function.

`PrivateDnsName`

The private DNS name of the specified instance. For example: `ip-10-24-34-0.ec2.internal`.

`PublicDnsName`

The public DNS name of the specified instance. For example: `ec2-107-20-50-45.compute-1.amazonaws.com`.

`PrivateIp`

The private IP address of the specified instance. For example: `10.24.34.0`.

`PublicIp`

The public IP address of the specified instance. For example: `192.0.2.0`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

EC2 Instance with an EBS Block Device Mapping

JSON

```

        ImageId: "ami-79fd7eee"
        KeyName: "testkey"
        BlockDeviceMappings:
          - DeviceName: "/dev/sdm"
```

```
            Ebs:
              VolumeType: "io1"
              Iops: "200"
              DeleteOnTermination: "false"
              VolumeSize: "20"
          - DeviceName: "/dev/sdk"
            NoDevice: {}
```

Automatically Assign a Public IP Address

You can associate a public IP address with a network interface only if it has a device index of `0` and if it is a new network interface (not an existing one).

JSON

```
"Ec2Instance" : {
  "Type" : "AWS::EC2::Instance",
  "Properties" : {
    "ImageId" : { "Fn::FindInMap" : [ "RegionMap", { "Ref" : "AWS::Region" }, "AMI" ]},
    "KeyName" : { "Ref" : "KeyName" },
    "NetworkInterfaces": [ {
      "AssociatePublicIpAddress": "true",
      "DeviceIndex": "0",
      "GroupSet": [{ "Ref" : "myVPCEC2SecurityGroup" }],
      "SubnetId": { "Ref" : "PublicSubnet" }
    } ]
  }
}
```

YAML

```
  Ec2Instance:
    Type: AWS::EC2::Instance
    Properties:
      ImageId:
        Fn::FindInMap:
          - "RegionMap"
          - Ref: "AWS::Region"
          - "AMI"
      KeyName:
        Ref: "KeyName"
      NetworkInterfaces:
        - AssociatePublicIpAddress: "true"
          DeviceIndex: "0"
          GroupSet:
            - Ref: "myVPCEC2SecurityGroup"
          SubnetId:
            Ref: "PublicSubnet"
```

Other Examples

You can download templates that show how to use `AWS::EC2::Instance` to create a virtual private cloud (VPC):

- Single instance in a single subnet
- Multiple subnets with ELB and Auto Scaling group

For more information about an `AWS::EC2::Instance` that has an IAM instance profile, see: Create an EC2 instance with an associated instance profile.

For more information about Amazon EC2 template examples, see: Amazon EC2 Template Snippets (p. 342).

Amazon EC2 Instance SsmAssociations AssociationParameters

`AssociationParameters` is a property of the Amazon EC2 Instance SsmAssociations (p. 1176) property that specifies input parameter values for an SSM document in AWS Systems Manager.

Syntax

JSON

```
{
  "Key" : String,
  "Value" : [ String, ... ]
}
```

YAML

```
Key: String
Value:
  - String
```

Properties

`Key`

The name of an input parameter that is in the associated SSM document.

Required: Yes

Type: String

`Value`

The value of an input parameter.

Required: Yes

Type: List of String values

Amazon EC2 BlockDeviceMapping

The Amazon EC2 block device mapping property is an embedded property of the AWS::EC2::Instance (p. 1155) resource. For block device mappings for an Auto Scaling launch configuration, see Amazon EC2 Auto Scaling LaunchConfiguration BlockDeviceMapping (p. 724).

Syntax

JSON

```
{
```

```
   "DeviceName (p. 1167)" : String,
   "Ebs (p. 1167)" : EC2 EBS Block Device,
   "NoDevice (p. 1167)" : Boolean,
   "VirtualName (p. 1167)" : String
}
```

YAML

```
DeviceName (p. 1167): String
Ebs (p. 1167): EC2 EBS Block Device
NoDevice (p. 1167): Boolean
VirtualName (p. 1167): String
```

Properties

`DeviceName`

The name of the device within Amazon EC2. For more information, see Device Naming on Linux Instances in the *Amazon EC2 User Guide for Linux Instances*.

Required: Yes

Type: String

`Ebs`

Required: Conditional You can specify either `VirtualName` or `Ebs`, but not both.

Type: Amazon Elastic Block Store Block Device (p. 1168).

`NoDevice`

This property can be used to unmap a defined device.

Required: No

Type: Boolean

`VirtualName`

The name of the virtual device. The name must be in the form `ephemeral`*X* where *X* is a number starting from zero (0); for example, `ephemeral0`.

Required: Conditional You can specify either `VirtualName` or `Ebs`, but not both.

Type: String

Examples

Block Device Mapping with two EBS Volumes

This example sets the EBS-backed root device (/dev/sda1) size to 50 GiB, and another EBS-backed device mapped to /dev/sdm that is 100 GiB in size.

```
"BlockDeviceMappings" : [
   {
      "DeviceName" : "/dev/sda1",
      "Ebs" : { "VolumeSize" : "50" }
   },
```

```
   {
      "DeviceName" : "/dev/sdm",
      "Ebs" : { "VolumeSize" : "100" }
   }
]
```

Block Device Mapping with an Ephemeral Drive

This example maps an ephemeral drive to device /dev/sdc.

```
"BlockDeviceMappings" : [
   {
      "DeviceName"  : "/dev/sdc",
      "VirtualName" : "ephemeral0"
   }
]
```

Unmapping an AMI-defined Device

To unmap a device defined in the AMI, set the `NoDevice` property to an empty map, as shown here:

```
{
   "DeviceName":"/dev/sde",
   "NoDevice": {}
}
```

See Also

- Amazon EC2 Instance Store in the *Amazon Elastic Compute Cloud User Guide*

Amazon Elastic Block Store Block Device

The Amazon Elastic Block Store block device type is an embedded property of the Amazon EC2 BlockDeviceMapping (p. 1166) property.

Syntax

JSON

```
{
   "DeleteOnTermination (p. 1169)" : Boolean,
   "Encrypted" : Boolean,
   "Iops (p. 1169)" : Number,
   "SnapshotId (p. 1169)" : String,
   "VolumeSize (p. 1169)" : String,
   "VolumeType (p. 1169)" : String
}
```

YAML

```
DeleteOnTermination (p. 1169): Boolean
Encrypted: Boolean
Iops (p. 1169): Number
SnapshotId (p. 1169): String
VolumeSize (p. 1169): String
```

```
VolumeType (p. 1169): String
```

Properties

`DeleteOnTermination`

Determines whether to delete the volume on instance termination. The default value is `true`.

Required: No

Type: Boolean

`Encrypted`

Indicates whether the volume is encrypted. Encrypted Amazon EBS volumes can only be attached to instance types that support Amazon EBS encryption. Volumes that are created from encrypted snapshots are automatically encrypted. You cannot create an encrypted volume from an unencrypted snapshot or vice versa. If your AMI uses encrypted volumes, you can only launch the AMI on supported instance types. For more information, see Amazon EBS encryption in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: Boolean

`Iops`

The number of I/O operations per second (IOPS) that the volume supports. This can be an integer from 100 – 20000.

Required: Conditional Required when the volume type (p. 1169) is `io1`; not used with other volume types.

Type: Number

`SnapshotId`

The snapshot ID of the volume to use to create a block device.

Required: Conditional If you specify both `SnapshotId` and `VolumeSize`, `VolumeSize` must be equal or greater than the size of the snapshot.

Type: String

`VolumeSize`

The volume size, in gibibytes (GiB). For valid values, see the `Size` parameter for the CreateVolume action in the *Amazon EC2 API Reference*.

Required: Conditional If you specify both `SnapshotId` and `VolumeSize`, `VolumeSize` must be equal or greater than the size of the snapshot.

Type: String

Update requires: Some interruptions (p. 121)

`VolumeType`

The volume type. If you set the type to `io1`, you must also set the `Iops` property. For valid values, see the `VolumeType` parameter for the CreateVolume action in the *Amazon EC2 API Reference*.

Required: No

Type: String

Example

```
{
   "DeviceName":"/dev/sdc",
   "Ebs":{
      "SnapshotId":"snap-xxxxxx",
      "VolumeSize":"50",
      "VolumeType":"io1",
      "Iops":"1000",
      "DeleteOnTermination":"false"
   }
}
```

See Also

- CreateVolume in the *Amazon Elastic Compute Cloud API Reference*

Amazon EC2 Instance CreditSpecification

The `CreditSpecification` property type specifies the credit option for CPU usage of a T2 instance.

`CreditSpecification` is a property of the AWS::EC2::Instance (p. 1155) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "CPUCredits" : String
}
```

YAML

```
CPUCredits: String
```

Properties

`CPUCredits`

The credit option for CPU usage of a T2 instance. Valid values are `standard` and `unlimited`. By default, `standard` is specified.

Required: No

Type: String

Update requires: No interruption (p. 120)

Amazon EC2 Instance ElasticGpuSpecification

The `ElasticGpuSpecification` property is part of the AWS::EC2::Instance (p. 1155) resource that specifies the type of Elastic GPU. An Elastic GPU is a GPU resource that you can attach to your Amazon EC2 instance to accelerate the graphics performance of your applications. For more information, see Amazon EC2 Elastic GPUs in the *Amazon EC2 User Guide for Windows Instances*.

Syntax

JSON

```
{
  "Type" : String
}
```

YAML

```
Type: String
```

Properties

`Type`

The type of Elastic GPU.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon EC2 Instance LaunchTemplateSpecification

The `LaunchTemplateSpecification` property type specifies the launch template to use. You must specify either the launch template ID or launch template name.

`LaunchTemplateSpecification` is a property of the AWS::EC2::Instance (p. 1155) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "LaunchTemplateId" : String,
  "LaunchTemplateName" : String,
  "Version" : String
}
```

YAML

```
LaunchTemplateId: String
LaunchTemplateName: String
Version: String
```

Properties

`LaunchTemplateId`

The ID of the launch template. You must specify either a template ID or a template name.

Minimum length of 1. Maximum length of 255. IDs must fit the following pattern:

`[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`LaunchTemplateName`

The name of the launch template. You must specify either a template name or a template ID.

Minimum length of 3. Maximum length of 128. Names must fit the following pattern:

`[a-zA-Z0-9\(\)\.-/_]+`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Version`

The version number. AWS CloudFormation does not support specifying `$Latest`, or `$Default` for the template version number.

Minimum length of 1. Maximum length of 255. Versions must fit the following pattern:

`[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

See Also

- LaunchTemplateSpecification in the *Amazon EC2 API Reference*

EC2 MountPoint

The EC2 MountPoint property is an embedded property of the AWS::EC2::Instance (p. 1155) type.

Syntax

JSON

```
{
  "Device (p. 1173)" : String,
  "VolumeId (p. 1173)" : String
}
```

YAML

```
Device (p. 1173): String,
VolumeId (p. 1173): String
```

Properties

`Device`

How the device is exposed to the instance (such as /dev/sdh, or xvdh).

Required: Yes

Type: String

`VolumeId`

The ID of the Amazon EBS volume. The volume and instance must be within the same Availability Zone and the instance must be running.

Required: Yes

Type: String

Example

This mount point (specified in the `Volumes` property in the EC2 instance) refers to a named EBS volume, "NewVolume".

```
"Ec2Instance" : {
   "Type" : "AWS::EC2::Instance",
   "Properties" : {
      "AvailabilityZone" : {
         "Fn::FindInMap" : [ "RegionMap", { "Ref" : "AWS::Region" }, "TestAz" ]
      },
      "SecurityGroups" : [ { "Ref" : "InstanceSecurityGroup" } ],
      "KeyName" : { "Ref" : "KeyName" },
      "ImageId" : {
         "Fn::FindInMap" : [ "RegionMap", { "Ref" : "AWS::Region" }, "AMI" ]
      },
      "Volumes" : [
         { "VolumeId" : { "Ref" : "NewVolume" }, "Device" : "/dev/sdk" }
      ]
   }
},
"NewVolume" : {
   "Type" : "AWS::EC2::Volume",
   "Properties" : {
      "Size" : "100",
      "AvailabilityZone" : {
         "Fn::FindInMap" : [ "RegionMap", { "Ref" : "AWS::Region" }, "TestAz" ]
      }
   }
}
```

See Also

- AWS::EC2::Instance (p. 1155)
- AWS::EC2::Volume (p. 1279)

EC2 NetworkInterface

The `EC2 Network Interface` type is an embedded property of the AWS::EC2::Instance (p. 1155) type. It specifies a network interface that is to be attached.

Syntax

JSON

```
{
  "AssociatePublicIpAddress (p. 1174)" : Boolean,
  "DeleteOnTermination (p. 1174)" : Boolean,
  "Description (p. 1174)" : String,
  "DeviceIndex (p. 1175)" : String,
  "GroupSet (p. 1175)" : [ String, ... ],
  "NetworkInterfaceId (p. 1175)" : String,
  "Ipv6AddressCount" : Integer,
  "Ipv6Addresses" : [ IPv6 Address Type, ... ],
  "PrivateIpAddress (p. 1175)" : String,
  "PrivateIpAddresses (p. 1175)" : [ PrivateIpAddressSpecification, ... ],
  "SecondaryPrivateIpAddressCount (p. 1176)" : Integer,
  "SubnetId (p. 1176)" : String
}
```

YAML

```
AssociatePublicIpAddress (p. 1174): Boolean
DeleteOnTermination (p. 1174): Boolean
Description (p. 1174): String
DeviceIndex (p. 1175): String
GroupSet (p. 1175):
  - String
NetworkInterfaceId (p. 1175): String
Ipv6AddressCount: Integer
Ipv6Addresses:
  - IPv6 Address Type
PrivateIpAddress (p. 1175): String
PrivateIpAddresses (p. 1175):
  - PrivateIpAddressSpecification
SecondaryPrivateIpAddressCount (p. 1176): Integer
SubnetId (p. 1176): String
```

Properties

`AssociatePublicIpAddress`

Indicates whether the network interface receives a public IP address. You can associate a public IP address with a network interface only if it has a device index of `eth0` and if it is a new network interface (not an existing one). In other words, if you specify true, don't specify a network interface ID. For more information, see Amazon EC2 Instance IP Addressing.

Required: No

Type: Boolean.

`DeleteOnTermination`

Whether to delete the network interface when the instance terminates.

Required: No

Type: Boolean.

`Description`

The description of this network interface.

Required: No

Type: String

`DeviceIndex`

The network interface's position in the attachment order.

Required: Yes

Type: String

`GroupSet`

A list of security group IDs associated with this network interface.

Required: No

Type: List of strings.

`NetworkInterfaceId`

An existing network interface ID.

Required: Conditional. If you don't specify the `SubnetId` property, you must specify this property.

Type: String

`Ipv6AddressCount`

The number of IPv6 addresses to associate with the network interface. Amazon EC2 automatically selects the IPv6 addresses from the subnet range. To specify specific IPv6 addresses, use the `Ipv6Addresses` property and don't specify this property.

For restrictions on which instance types support IPv6 addresses, see the RunInstances action in the *Amazon EC2 API Reference*.

Required: No

Type: Integer

`Ipv6Addresses`

One or more specific IPv6 addresses from the IPv6 CIDR block range of your subnet to associate with the network interface. To specify a number of IPv6 addresses, use the `Ipv6AddressCount` property and don't specify this property.

For information about restrictions on which instance types support IPv6 addresses, see the RunInstances action in the *Amazon EC2 API Reference*.

Required: No

Type: List of EC2 NetworkInterface Ipv6Addresses (p. 1213)

`PrivateIpAddress`

Assigns a single private IP address to the network interface, which is used as the primary private IP address. If you want to specify multiple private IP address, use the `PrivateIpAddresses` property.

Required: No

Type: String

`PrivateIpAddresses`

Assigns a list of private IP addresses to the network interface. You can specify a primary private IP address by setting the value of the `Primary` property to `true` in the `PrivateIpAddressSpecification` property. If you want Amazon EC2 to automatically assign

private IP addresses, use the `SecondaryPrivateIpAddressCount` property and do not specify this property.

For information about the maximum number of private IP addresses, see Private IP Addresses Per ENI Per Instance Type in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: list of PrivateIpAddressSpecification (p. 1213)

`SecondaryPrivateIpAddressCount`

The number of secondary private IP addresses that Amazon EC2 auto assigns to the network interface. Amazon EC2 uses the value of the `PrivateIpAddress` property as the primary private IP address. If you don't specify that property, Amazon EC2 auto assigns both the primary and secondary private IP addresses.

If you want to specify your own list of private IP addresses, use the `PrivateIpAddresses` property and do not specify this property.

For information about the maximum number of private IP addresses, see Private IP Addresses Per ENI Per Instance Type in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: Integer.

`SubnetId`

The ID of the subnet to associate with the network interface.

Required: Conditional. If you don't specify the `NetworkInterfaceId` property, you must specify this property.

Type: String

Amazon EC2 Instance SsmAssociations

`SsmAssociations` is a property of the AWS::EC2::Instance (p. 1155) resource that specifies the SSM document and parameter values in AWS Systems Manager to associate with an instance.

Syntax

JSON

```
{
  "AssociationParameters" : [ Parameters, ... ],
  "DocumentName" : String
}
```

YAML

```
AssociationParameters:
  - Parameters
DocumentName: String
```

Properties

`AssociationParameters`

The input parameter values to use with the associated SSM document.

Required: No

Type: List of Amazon EC2 Instance SsmAssociations AssociationParameters (p. 1166)

`DocumentName`

The name of an SSM document to associate with the instance.

Required: Yes

Type: String

AWS::EC2::InternetGateway

Creates a new Internet gateway in your AWS account. After creating the Internet gateway, you then attach it to a VPC.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::InternetGateway",
   "Properties" : {
      "Tags (p. 1177)" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::EC2::InternetGateway
Properties:
  Tags (p. 1177):
    - Resource Tag
```

Properties

`Tags`

An arbitrary set of tags (key–value pairs) for this resource.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myInternetGateway" : {
         "Type" : "AWS::EC2::InternetGateway",
         "Properties" : {
            "Tags" : [ {"Key" : "foo", "Value" : "bar"}]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  myInternetGateway:
    Type: AWS::EC2::InternetGateway
    Properties:
      Tags:
      - Key: foo
        Value: bar
```

Related Information

- CreateInternetGateway in the *Amazon EC2 API Reference*.
- Use the AWS::EC2::VPCGatewayAttachment (p. 1301) resource to associate an Internet gateway with a VPC.

AWS::EC2::LaunchTemplate

The `AWS::EC2::LaunchTemplate` resource creates a launch template for an Amazon EC2 instance. A launch template contains the parameters to launch an instance. For more information, see CreateLaunchTemplate in the *Amazon EC2 API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::LaunchTemplate",
  "Properties" : {
    "LaunchTemplateName" : String,
    "LaunchTemplateData" : LaunchTemplateData (p. 1187)
  }
}
```

YAML

```
Type: "AWS::EC2::LaunchTemplate"
```

```
Properties:
  LaunchTemplateName: String
  LaunchTemplateData: LaunchTemplateData (p. 1187)
```

Properties

`LaunchTemplateName`

A name for the launch template.

Length Constraints: Minimum length of 3. Maximum length of 128.

Pattern: [a-zA-Z0-9\(\)\.-/_]+

Required: No

Type: String

Update requires: Replacement (p. 121)

`LaunchTemplateData`

The information for the launch template.

Required: No

Type: LaunchTemplateData (p. 1187)

Update requires: No interruption (p. 120)

Return Values

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`LatestVersionNumber`

The latest version of the launch template, such as `5`.

`DefaultVersionNumber`

The default version of the launch template, such as `2`.

> **Note**
> The default version of a launch template cannot be specified in AWS CloudFormation. The default version can be set in the Amazon EC2 Console or by using the `modify-launch-template` AWS CLI command.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Ref

When you pass the logical ID of an `AWS::EC2::LaunchTemplate` resource to the intrinsic `Ref` function, `Ref` returns the ID of the launch template, such as `lt-01238c059e3466abc`.

For more information about using the `Ref` function, see Ref (p. 2341).

See Also

- CreateLaunchTemplate in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate BlockDeviceMapping

The `BlockDeviceMapping` property type describes a block device mapping for an Amazon EC2 launch template.

`BlockDeviceMapping` is a property of the Amazon EC2 LaunchTemplate LaunchTemplateData (p. 1187) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Ebs" : Ebs (p. 1182),
  "NoDevice" : String,
  "VirtualName" : String,
  "DeviceName" : String
}
```

YAML

```
Ebs: Ebs (p. 1182)
NoDevice: String
VirtualName: String
DeviceName: String
```

Properties

`DeviceName`

The device name (for example, /dev/sdh or xvdh).

Required: No

Type: String

Update requires: No interruption (p. 120)

`Ebs`

Parameters used to automatically set up EBS volumes when the instance is launched.

Required: No

Type: Ebs (p. 1182)

Update requires: No interruption (p. 120)

`NoDevice`

Suppresses the specified device included in the block device mapping of the AMI.

Required: No

Type: String

Update requires: No interruption (p. 120)

`VirtualName`

The virtual device name (ephemeralN). Instance store volumes are numbered starting from 0. An instance type with 2 available instance store volumes can specify mappings for ephemeral0 and ephemeral1. The number of available instance store volumes depends on the instance type. After you connect to the instance, you must mount the volume.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- LaunchTemplateBlockDeviceMappingRequest in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate CreditSpecification

The `CreditSpecification` property type specifies the credit option for CPU usage of a T2 instance for an Amazon EC2 launch template.

`CreditSpecification` is a property of the Amazon EC2 LaunchTemplate LaunchTemplateData (p. 1187) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "CpuCredits" : String
}
```

YAML

```
CpuCredits: String
```

Properties

`CpuCredits`

The credit option for CPU usage of a T2 instance. Valid values include `standard` and `unlimited`.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- CreditSpecificationRequest in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate Ebs

The `Ebs` property type specifies parameters for a block device for an EBS volume in a Amazon EC2 launch template.

`Ebs` is a property of the Amazon EC2 LaunchTemplate BlockDeviceMapping (p. 1180) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SnapshotId" : String,
  "VolumeType" : String,
  "KmsKeyId" : String,
  "Encrypted" : Boolean,
  "Iops" : Integer,
  "VolumeSize" : Integer,
  "DeleteOnTermination" : Boolean
}
```

YAML

```
SnapshotId: String
VolumeType: String
KmsKeyId: String
Encrypted: Boolean
Iops: Integer
VolumeSize: Integer
DeleteOnTermination: Boolean
```

Properties

`DeleteOnTermination`

Indicates whether the EBS volume is deleted on instance termination.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Encrypted`

Indicates whether the EBS volume is encrypted. Encrypted volumes can only be attached to instances that support Amazon EBS encryption. If you are creating a volume from a snapshot, you can't specify an encryption value.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Iops`

The number of I/O operations per second (IOPS) that the volume supports. For io1, this represents the number of IOPS that are provisioned for the volume. For gp2, this represents the baseline

performance of the volume and the rate at which the volume accumulates I/O credits for bursting. For more information about General Purpose SSD baseline performance, I/O credits, and bursting, see Amazon EBS Volume Types in the *Amazon EC2 User Guide for Linux Instances*.

Condition: This parameter is required for requests to create io1 volumes; it is not used in requests to create gp2, st1, sc1, or standard volumes.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`KmsKeyId`

The ARN of the AWS Key Management Service (AWS KMS) CMK used for encryption.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SnapshotId`

The ID of the snapshot.

Required: No

Type: String

Update requires: No interruption (p. 120)

`VolumeSize`

The size of the volume, in GiB.

Default: If you're creating the volume from a snapshot and don't specify a volume size, the default is the snapshot size.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`VolumeType`

The volume type.

Valid values include: `standard`, `io1`, `gp2`, `sc1`, and `st1`.

Required: No

Type: String

Update requires: No interruption (p. 120)

Amazon EC2 LaunchTemplate ElasticGpuSpecification

The `ElasticGpuSpecification` property type specifies a specification for an Elastic GPU for an Amazon EC2 launch template.

`ElasticGpuSpecification` is a property of the Amazon EC2 LaunchTemplate LaunchTemplateData (p. 1187) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : String
}
```

YAML

```
Type: String
```

Properties

`Type`

The type of Elastic GPU.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- ElasticGpuSpecification in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate IamInstanceProfile

The `IamInstanceProfile` property type specifies an IAM instance profile for an Amazon EC2 launch template.

`IamInstanceProfile` is a property of the Amazon EC2 LaunchTemplate LaunchTemplateData (p. 1187) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Arn" : String,
  "Name" : String
```

```
}
```

YAML

```
Arn: String
Name: String
```

Properties

`Arn`

The Amazon Resource Name (ARN) of the instance profile.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the instance profile.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- LaunchTemplateIamInstanceProfileSpecificationRequest in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate InstanceMarketOptions

The `InstanceMarketOptions` property type specifies market (purchasing) option for instances in an Amazon EC2 launch template.

`InstanceMarketOptions` is a property of the Amazon EC2 LaunchTemplate LaunchTemplateData (p. 1187) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SpotOptions" : SpotOptions (p. 1197),
  "MarketType" : String
}
```

YAML

```
SpotOptions: SpotOptions (p. 1197)
MarketType: String
```

Properties

`MarketType`

The market type.

Valid values include: `spot`

Required: No

Type: String

Update requires: No interruption (p. 120)

`SpotOptions`

The options for Spot Instances.

Required: No

Type: SpotOptions (p. 1197)

Update requires: No interruption (p. 120)

See Also

- LaunchTemplateInstanceMarketOptionsRequest in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate Ipv6Add

The `Ipv6Add` property type describes an IPv6 address in an Amazon EC2 launch template.

`Ipv6Add` is a property of the Amazon EC2 LaunchTemplate NetworkInterface (p. 1192) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Ipv6Address" : String
}
```

YAML

```
Ipv6Address: String
```

Properties

`Ipv6Address`

The IPv6 address.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- InstanceIpv6AddressRequest in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate LaunchTemplateData

The `LaunchTemplateData` property type specifies the information to include the launch template for an Amazon EC2 instance.

`LaunchTemplateData` is a property of the AWS::EC2::LaunchTemplate (p. 1178) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SecurityGroups" : [ String, ... ],
  "TagSpecifications" : [ TagSpecification (p. 1198), ... ],
  "UserData" : String,
  "InstanceInitiatedShutdownBehavior" : String,
  "BlockDeviceMappings" : [ BlockDeviceMapping (p. 1180), ... ],
  "IamInstanceProfile" : IamInstanceProfile (p. 1184),
  "KernelId" : String,
  "SecurityGroupIds" : [ String, ... ],
  "EbsOptimized" : Boolean,
  "KeyName" : String,
  "DisableApiTermination" : Boolean,
  "ElasticGpuSpecifications" : [ ElasticGpuSpecification (p. 1184), ... ],
  "Placement" : Placement (p. 1195),
  "InstanceMarketOptions" : InstanceMarketOptions (p. 1185),
  "NetworkInterfaces" : [ NetworkInterface (p. 1192), ... ],
  "ImageId" : String,
  "InstanceType" : String,
  "RamDiskId" : String,
  "Monitoring" : Monitoring (p. 1191),
  "CreditSpecification" : CreditSpecification (p. 1181)
}
```

YAML

```
SecurityGroups:
  - String
TagSpecifications:
  - TagSpecification (p. 1198)
UserData: String
InstanceInitiatedShutdownBehavior: String
BlockDeviceMappings:
  - BlockDeviceMapping (p. 1180)
IamInstanceProfile: IamInstanceProfile (p. 1184)
KernelId: String
SecurityGroupIds:
  - String
EbsOptimized: Boolean
KeyName: String
DisableApiTermination: Boolean
```

```
ElasticGpuSpecifications:
  - ElasticGpuSpecification (p. 1184)
Placement: Placement (p. 1195)
InstanceMarketOptions: InstanceMarketOptions (p. 1185)
NetworkInterfaces:
  - NetworkInterface (p. 1192)
ImageId: String
InstanceType: String
RamDiskId: String
Monitoring: Monitoring (p. 1191)
CreditSpecification: CreditSpecification (p. 1181)
```

Properties

`BlockDeviceMappings`

The block device mapping.

Required: No

Type: List of BlockDeviceMapping (p. 1180)

Update requires: No interruption (p. 120)

`CreditSpecification`

The credit option for CPU usage of the instance. Valid for T2 instances only.

Required: No

Type: CreditSpecification (p. 1181)

Update requires: No interruption (p. 120)

`DisableApiTermination`

If set to `true`, you can't terminate the instance using the Amazon EC2 console, CLI, or API.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`EbsOptimized`

Indicates whether the instance is optimized for Amazon EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal Amazon EBS I/O performance. This optimization isn't available with all instance types. Additional usage charges apply when using an EBS-optimized instance.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`ElasticGpuSpecifications`

An elastic GPU to associate with the instance.

Required: No

Type: List of ElasticGpuSpecification (p. 1184)

Update requires: No interruption (p. 120)

`IamInstanceProfile`

The IAM instance profile.

Required: No

Type: IamInstanceProfile (p. 1184)

Update requires: No interruption (p. 120)

`ImageId`

The ID of the AMI. For more information, see DescribeImages in the *Amazon EC2 API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`InstanceInitiatedShutdownBehavior`

Indicates whether an instance stops or terminates when you initiate shutdown from the instance (using the operating system command for system shutdown).

Valid values include `stop` and `terminate`. The default is `stop`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`InstanceMarketOptions`

The market (purchasing) option for the instances.

Required: No

Type: InstanceMarketOptions (p. 1185)

Update requires: No interruption (p. 120)

`InstanceType`

The instance type. For a list of valid values, see RequestLaunchTemplateData in the *Amazon EC2 API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`KernelId`

The ID of the kernel.

> **Important**
> We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see User Provided Kernels in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`KeyName`

The name of the key pair. For information on creating a key pair, see CreateKeyPair or ImportKeyPair in the *Amazon EC2 API Reference*.

> **Important**
> If you do not specify a key pair, you can't connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Monitoring`

The monitoring for the instance.

Required: No

Type: Monitoring (p. 1191)

Update requires: No interruption (p. 120)

`NetworkInterfaces`

One or more network interfaces.

Required: No

Type: List of NetworkInterface (p. 1192)

Update requires: No interruption (p. 120)

`Placement`

The placement for the instance.

Required: No

Type: Placement (p. 1195)

Update requires: No interruption (p. 120)

`RamDiskId`

The ID of the RAM disk.

> **Important**
> We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see User Provided Kernels in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SecurityGroups`

[EC2-Classic, default VPC] One or more security group names. For a nondefault VPC, you must use security group IDs instead. You cannot specify both a security group ID and security name in the same request.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SecurityGroupIds`

One or more security group IDs. You cannot specify both a security group ID and security name in the same request. For information on creating a security group, see CreateSecurityGroup in the *Amazon EC2 API Reference*.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`TagSpecifications`

The tags to apply to the resources during launch. You can tag instances and volumes. The specified tags are applied to all instances or volumes that are created during launch.

Required: No

Type: List of TagSpecification (p. 1198)

Update requires: No interruption (p. 120)

`UserData`

The Base64-encoded user data to make available to the instance. For more information, see Running Commands on Your Linux Instance at Launch in the *Amazon EC2 User Guide for Linux Instances* and Adding User Data in the *Amazon EC2 User Guide for Windows Instances*.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- RequestLaunchTemplateData in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate Monitoring

The `Monitoring` property type describes the monitoring for the instance of an Amazon EC2 launch template.

`Monitoring` is a property of the Amazon EC2 LaunchTemplate LaunchTemplateData (p. 1187) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Enabled" : Boolean
}
```

YAML

```
Enabled: Boolean
```

Properties

`Enabled`

Specify `true` to enable detailed monitoring. Otherwise, basic monitoring is enabled.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

See Also

- LaunchTemplatesMonitoringRequest in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate NetworkInterface

The `NetworkInterface` property type specifies parameters for a network interface in an Amazon EC2 launch template.

`NetworkInterface` is a property of the Amazon EC2 LaunchTemplate LaunchTemplateData (p. 1187) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Description" : String,
  "PrivateIpAddress" : String,
  "PrivateIpAddresses" : [ PrivateIpAdd (p. 1196), ... ],
  "SecondaryPrivateIpAddressCount" : Integer,
  "Ipv6AddressCount" : Integer,
  "Groups" : [ String, ... ],
  "DeviceIndex" : Integer,
  "SubnetId" : String,
  "Ipv6Addresses" : [ Ipv6Add (p. 1186), ... ],
  "AssociatePublicIpAddress" : Boolean,
  "NetworkInterfaceId" : String,
  "DeleteOnTermination" : Boolean
}
```

YAML

```
Description: String
```

```
PrivateIpAddress: String
PrivateIpAddresses:
  - PrivateIpAdd (p. 1196)
SecondaryPrivateIpAddressCount: Integer
Ipv6AddressCount: Integer
Groups:
  - String
DeviceIndex: Integer
SubnetId: String
Ipv6Addresses:
  - Ipv6Add (p. 1186)
AssociatePublicIpAddress: Boolean
NetworkInterfaceId: String
DeleteOnTermination: Boolean
```

Properties

`AssociatePublicIpAddress`

Associates a public IPv4 address with eth0 for a new network interface.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`DeleteOnTermination`

Indicates whether the network interface is deleted when the instance is terminated.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Description`

A description for the network interface.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DeviceIndex`

The device index for the network interface attachment.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Groups`

The IDs of one or more security groups.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Ipv6AddressCount`

The number of IPv6 addresses to assign to a network interface. Amazon EC2 automatically selects the IPv6 addresses from the subnet range. You can't use this option if specifying specific IPv6 addresses.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Ipv6Addresses`

One or more specific IPv6 addresses from the IPv6 CIDR block range of your subnet. You can't use this option if you're specifying a number of IPv6 addresses.

Required: No

Type: List of Ipv6Add (p. 1186)

Update requires: No interruption (p. 120)

`NetworkInterfaceId`

The ID of the network interface.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PrivateIpAddress`

The primary private IPv4 address of the network interface.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PrivateIpAddresses`

One or more private IPv4 addresses.

Required: No

Type: List of PrivateIpAdd (p. 1196)

Update requires: No interruption (p. 120)

`SecondaryPrivateIpAddressCount`

The number of secondary private IPv4 addresses to assign to a network interface.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`SubnetId`

The ID of the subnet for the network interface.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- LaunchTemplateInstanceNetworkInterfaceSpecificationRequest in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate Placement

The `Placement` property type specifies the placement for the instance in an Amazon EC2 launch template.

`Placement` is a property of the Amazon EC2 LaunchTemplate LaunchTemplateData (p. 1187) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "GroupName" : String,
  "Tenancy" : String,
  "AvailabilityZone" : String,
  "Affinity" : String,
  "HostId" : String
}
```

YAML

```
GroupName: String
Tenancy: String
AvailabilityZone: String
Affinity: String
HostId: String
```

Properties

`Affinity`

The affinity setting for an instance on a Dedicated Host.

Required: No

Type: String

Update requires: No interruption (p. 120)

`AvailabilityZone`

The Availability Zone for the instance.

Required: No

Type: String

Update requires: No interruption (p. 120)

`GroupName`

The name of the placement group for the instance.

Required: No

Type: String

Update requires: No interruption (p. 120)

`HostId`

The ID of the Dedicated Host for the instance.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Tenancy`

The tenancy of the instance (if the instance is running in a VPC). An instance with a tenancy of dedicated runs on single-tenant hardware.

Valid values include `default`, `dedicated`, and `host`.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- LaunchTemplatePlacementRequest in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate PrivateIpAdd

The `PrivateIpAdd` property type describes a private IPv4 address for a network interface in an Amazon EC2 launch template.

`PrivateIpAdd` is a property of the Amazon EC2 LaunchTemplate NetworkInterface (p. 1192) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "PrivateIpAddress" : String,
  "Primary" : Boolean
```

```
}
```

YAML

```
PrivateIpAddress: String
Primary: Boolean
```

Properties

`Primary`

Indicates whether the private IPv4 address is the primary private IPv4 address. Only one IPv4 address can be designated as primary.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`PrivateIpAddress`

The private IPv4 address.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- PrivateIpAddressSpecification in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate SpotOptions

The `SpotOptions` property type specifies the options for Spot Instances in an Amazon EC2 launch template.

`SpotOptions` is a property of the Amazon EC2 LaunchTemplate InstanceMarketOptions (p. 1185) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SpotInstanceType" : String,
  "InstanceInterruptionBehavior" : String,
  "MaxPrice" : String
}
```

YAML

```
SpotInstanceType: String
InstanceInterruptionBehavior: String
MaxPrice: String
```

Properties

`InstanceInterruptionBehavior`

The behavior when a Spot Instance is interrupted. The default is `terminate`.

Valid values include: `hibernate`, `stop`, and `terminate`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`MaxPrice`

The maximum hourly price you're willing to pay for the Spot Instances.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SpotInstanceType`

The Spot Instance request type.

Valid values include: `one-time` and `persistent`.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- LaunchTemplateSpotMarketOptionsRequest in the *Amazon EC2 API Reference*

Amazon EC2 LaunchTemplate TagSpecification

The `TagSpecification` property type specifies the tags specification for an Amazon EC2 launch template.

`TagSpecification` is a property of the Amazon EC2 LaunchTemplate LaunchTemplateData (p. 1187) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "ResourceType" : String,
  "Tags" : [ Tag (p. 2258), ... ]
}
```

YAML

```
ResourceType: String
Tags:
  - Tag (p. 2258)
```

Properties

`ResourceType`

The type of resource to tag. Currently, the resource types that support tagging on creation are `instance` and `volume`.

For a list of valid values, see LaunchTemplateTagSpecificationRequest in the *Amazon EC2 API Reference*

Required: No

Type: String

Update requires: No interruption (p. 120)

`Tags`

The tags to apply to the resource.

Required: No

Type: List of Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

See Also

- LaunchTemplateTagSpecificationRequest in the *Amazon EC2 API Reference*

AWS::EC2::NatGateway

The `AWS::EC2::NatGateway` resource creates a network address translation (NAT) gateway in the specified public subnet. Use a NAT gateway to allow instances in a private subnet to connect to the Internet or to other AWS services, but prevent the Internet from initiating a connection with those instances. For more information and a sample architectural diagram, see NAT Gateways in the *Amazon VPC User Guide*.

> **Note**
> If you add a default route (`AWS::EC2::Route` resource) that points to a NAT gateway, specify NAT gateway's ID for the route's `NatGatewayId` property.

Topics

- Syntax (p. 1200)
- Properties (p. 1200)
- Return Value (p. 1201)

- Example (p. 1201)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::NatGateway",
  "Properties" : {
    "AllocationId" : String,
    "SubnetId" : String,
    "Tags" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: AWS::EC2::NatGateway
Properties:
  AllocationId: String
  SubnetId: String
  Tags:
    - Resource Tag
```

Properties

`AllocationId`

The allocation ID of an Elastic IP address to associate with the NAT gateway. If the Elastic IP address is associated with another resource, you must first disassociate it.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SubnetId`

The public subnet in which to create the NAT gateway.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this resource. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Value

Ref

When you pass the logical ID of an `AWS::EC2::NatGateway` resource to the intrinsic `Ref` function, the function returns the ID of the NAT gateway, such as `nat-0a12bc456789de0fg`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a NAT gateway and a route that associates the NAT gateway with a route table. The route table must be associated with an Internet gateway so that the NAT gateway can connect to the Internet.

JSON

```
"NAT" : {
  "DependsOn" : "VPCGatewayAttach",
  "Type" : "AWS::EC2::NatGateway",
  "Properties" : {
    "AllocationId" : { "Fn::GetAtt" : ["EIP", "AllocationId"]},
    "SubnetId" : { "Ref" : "Subnet"},
    "Tags" : [ {"Key" : "foo", "Value" : "bar" } ]
  }
},
"EIP" : {
  "Type" : "AWS::EC2::EIP",
  "Properties" : {
    "Domain" : "vpc"
  }
},
"Route" : {
  "Type" : "AWS::EC2::Route",
  "Properties" : {
    "RouteTableId" : { "Ref" : "RouteTable" },
    "DestinationCidrBlock" : "0.0.0.0/0",
    "NatGatewayId" : { "Ref" : "NAT" }
  }
}
```

YAML

```
NAT:
  DependsOn: VPCGatewayAttach
  Type: AWS::EC2::NatGateway
  Properties:
    AllocationId:
      Fn::GetAtt:
      - EIP
      - AllocationId
    SubnetId:
      Ref: Subnet
    Tags:
      - Key: foo
        Value: bar
EIP:
  Type: AWS::EC2::EIP
  Properties:
    Domain: vpc
Route:
  Type: AWS::EC2::Route
  Properties:
```

```
    RouteTableId:
      Ref: RouteTable
    DestinationCidrBlock: 0.0.0.0/0
    NatGatewayId:
      Ref: NAT
```

AWS::EC2::NetworkAcl

Creates a new network ACL in a VPC.

Topics

- Syntax (p. 1202)
- Properties (p. 1202)
- Return Values (p. 1203)
- Example (p. 1203)
- See Also (p. 1203)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::NetworkAcl",
   "Properties" : {
      "Tags (p. 1202)" : [ Resource Tag, ... ],
      "VpcId (p. 1202)" : String
   }
}
```

YAML

```
Type: AWS::EC2::NetworkAcl
Properties:
  Tags (p. 1202):
    - Resource Tag
  VpcId (p. 1202): String
```

Properties

`Tags`

An arbitrary set of tags (key–value pairs) for this ACL.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

`VpcId`

The ID of the VPC where the network ACL will be created.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myNetworkAcl" : {
         "Type" : "AWS::EC2::NetworkAcl",
         "Properties" : {
            "VpcId" : { "Ref" : "myVPC" },
            "Tags" : [ { "Key" : "foo", "Value" : "bar" } ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  myNetworkAcl:
    Type: AWS::EC2::NetworkAcl
    Properties:
      VpcId:
        Ref: myVPC
      Tags:
      - Key: foo
        Value: bar
```

See Also

- CreateNetworkAcl in the *Amazon EC2 API Reference*
- Network ACLs in the *Amazon Virtual Private Cloud User Guide*.

AWS::EC2::NetworkAclEntry

Creates an entry (i.e., a rule) in a network ACL with a rule number you specify. Each network ACL has a set of numbered ingress rules and a separate set of numbered egress rules.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::NetworkAclEntry",
   "Properties" : {
      "CidrBlock (p. 1204)" : String,
      "Egress (p. 1204)" : Boolean,
      "Icmp (p. 1204)" : EC2 ICMP,
      "Ipv6CidrBlock" : String,
      "NetworkAclId (p. 1205)" : String,
      "PortRange (p. 1205)" : EC2 PortRange,
      "Protocol (p. 1205)" : Integer,
      "RuleAction (p. 1205)" : String,
      "RuleNumber (p. 1205)" : Integer
   }
}
```

YAML

```
Type: AWS::EC2::NetworkAclEntry
Properties:
  CidrBlock (p. 1204): String
  Egress (p. 1204): Boolean
  Icmp (p. 1204):
    EC2 ICMP
  Ipv6CidrBlock: String
  NetworkAclId (p. 1205): String
  PortRange (p. 1205):
    EC2 PortRange
  Protocol (p. 1205): Integer
  RuleAction (p. 1205) : String
  RuleNumber (p. 1205) : Integer
```

Properties

`CidrBlock`

The IPv4 CIDR range to allow or deny, in CIDR notation (e.g., 172.16.0.0/24).

Required: Conditional. You must specify the `CidrBlock` or `Ipv6CidrBlock` property.

Type: String

Update requires: No interruption (p. 120)

`Egress`

Whether this rule applies to egress traffic from the subnet (`true`) or ingress traffic to the subnet (`false`). By default, AWS CloudFormation specifies `false`.

Required: No

Type: Boolean

Update requires: Replacement (p. 121).

`Icmp`

The Internet Control Message Protocol (ICMP) code and type.

Required: Conditional required if specifying 1 (ICMP) for the protocol parameter.

Type: EC2 NetworkAclEntry Icmp (p. 1207)

Update requires: No interruption (p. 120)

`Ipv6CidrBlock`

The IPv6 CIDR range to allow or deny, in CIDR notation.

Required: Conditional. You must specify the `CidrBlock` or `Ipv6CidrBlock` property.

Type: String

Update requires: No interruption (p. 120)

`NetworkAclId`

ID of the ACL where the entry will be created.

Required: Yes

Type: String

Update requires: Replacement (p. 121).

`PortRange`

The range of port numbers for the UDP/TCP protocol.

Required: Conditional Required if specifying 6 (TCP) or 17 (UDP) for the protocol parameter.

Type: EC2 NetworkAclEntry PortRange (p. 1207)

Update requires: No interruption (p. 120)

`Protocol`

The IP protocol that the rule applies to. You must specify `-1` or a protocol number (go to Protocol Numbers at iana.org). You can specify `-1` for all protocols.

> **Note**
> If you specify `-1`, all ports are opened and the `PortRange` property is ignored.

Required: Yes

Type: Number

Update requires: No interruption (p. 120)

`RuleAction`

Whether to allow or deny traffic that matches the rule; valid values are "allow" or "deny".

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RuleNumber`

Rule number to assign to the entry, such as `100`. ACL entries are processed in ascending order by rule number. Entries can't use the same rule number unless one is an egress rule and the other is an ingress rule. For valid values, see the CreateNetworkAclEntry action in the *Amazon EC2 API Reference*.

Required: Yes

Type: Number

Update requires: Replacement (p. 121).

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myNetworkAclEntry" : {
         "Type" : "AWS::EC2::NetworkAclEntry",
         "Properties" : {
            "NetworkAclId" : { "Ref" : "myNetworkAcl" },
            "RuleNumber" : "100",
            "Protocol" : "-1",
            "RuleAction" : "allow",
            "Egress" : "true",
            "CidrBlock" : "172.16.0.0/24",
            "Icmp" : { "Code" : "-1", "Type" : "-1" },
            "PortRange" : { "From" : "53", "To" : "53" }
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  myNetworkAclEntry:
    Type: AWS::EC2::NetworkAclEntry
    Properties:
      NetworkAclId:
        Ref: myNetworkAcl
      RuleNumber: '100'
      Protocol: "-1"
      RuleAction: allow
      Egress: 'true'
      CidrBlock: 172.16.0.0/24
      Icmp:
        Code: "-1"
        Type: "-1"
      PortRange:
        From: '53'
        To: '53'
```

- NetworkAclEntry in the *Amazon EC2 API Reference*

- Network ACLs in the *Amazon Virtual Private Cloud User Guide*.

EC2 NetworkAclEntry Icmp

The `Icmp` property is an embedded property of the AWS::EC2::NetworkAclEntry (p. 1203) type.

Syntax

JSON

```
{
   "Code" : Integer,
   "Type" : Integer
}
```

YAML

```
Code: Integer
Type: Integer
```

Properties

`Code`

The Internet Control Message Protocol (ICMP) code. You can use -1 to specify all ICMP codes for the given ICMP type.

Required: Conditional. Required if you specify `1` (ICMP) for the CreateNetworkAclEntry protocol parameter.

Type: Integer

`Type`

The Internet Control Message Protocol (ICMP) type. You can use -1 to specify all ICMP types.

Required: Conditional. Required if you specify `1` (ICMP) for the CreateNetworkAclEntry protocol parameter.

Type: Integer

EC2 NetworkAclEntry PortRange

The `PortRange` property is an embedded property of the AWS::EC2::NetworkAclEntry (p. 1203) type.

Syntax

JSON

```
{
   "From" : Integer,
   "To" : Integer
}
```

YAML

```
From: Integer
```

```
To: Integer
```

Properties

`From`

The first port in the range.

Required: Conditional. Required if you specify 6 (TCP) or 17 (UDP) for the protocol parameter.

Type: Integer

`To`

The last port in the range.

Required: Conditional. Required if you specify 6 (TCP) or 17 (UDP) for the protocol parameter.

Type: Integer

AWS::EC2::NetworkInterface

Describes a network interface in an Elastic Compute Cloud (EC2) instance for AWS CloudFormation. This is provided in a list in the `NetworkInterfaces` property of AWS::EC2::Instance (p. 1155).

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::NetworkInterface",
   "Properties" : {
      "Description" : String,
      "GroupSet" : [ String, ... ],
      "Ipv6AddressCount" : Integer,
      "Ipv6Addresses" : [ Ipv6Address, ... ],
      "PrivateIpAddress" : String,
      "PrivateIpAddresses" : [ PrivateIpAddressSpecification, ... ],
      "SecondaryPrivateIpAddressCount" : Integer,
      "SourceDestCheck" : Boolean,
      "SubnetId" : String,
      "Tags" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::EC2::NetworkInterface
Properties:
  Description: String
  GroupSet:
    - String
  Ipv6AddressCount: Integer
  Ipv6Addresses:
    - Ipv6Address
  PrivateIpAddress: String
  PrivateIpAddresses:
```

```
    - PrivateIpAddressSpecification
  SecondaryPrivateIpAddressCount: Integer
  SourceDestCheck: Boolean
  SubnetId: String
  Tags:
    - Resource Tag
```

Properties

`Description`

The description of this network interface.

Required: No

Type: String

Update requires: No interruption (p. 120).

`GroupSet`

A list of security group IDs associated with this network interface.

Required: No

Type: List of strings.

Update requires: No interruption (p. 120)

`Ipv6AddressCount`

The number of IPv6 addresses to associate with the network interface. EC2 automatically selects the IPv6 addresses from the subnet range. To specify specific IPv6 addresses, use the `Ipv6Addresses` property and don't specify this property.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Ipv6Addresses`

One or more specific IPv6 addresses from the IPv6 CIDR block range of your subnet to associate with the network interface. If you're specifying a number of IPv6 addresses, use the `Ipv6AddressCount` property and don't specify this property.

Required: No

Type: List of EC2 NetworkInterface Ipv6Addresses (p. 1213)

Update requires: No interruption (p. 120)

`PrivateIpAddress`

Assigns a single private IP address to the network interface, which is used as the primary private IP address. If you want to specify multiple private IP address, use the `PrivateIpAddresses` property.

Required: No

Type: String

Update requires: Replacement (p. 121).

`PrivateIpAddresses`

Assigns a list of private IP addresses to the network interface. You can specify a primary private IP address by setting the value of the `Primary` property to `true` in the `PrivateIpAddressSpecification` property. If you want EC2 to automatically assign private IP addresses, use the `SecondaryPrivateIpAddressCount` property and do not specify this property.

For information about the maximum number of private IP addresses, see Private IP Addresses Per ENI Per Instance Type in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: list of PrivateIpAddressSpecification (p. 1213).

Update requires: Replacement (p. 121) if you change the primary private IP address. If not, update requires No interruption (p. 120).

`SecondaryPrivateIpAddressCount`

The number of secondary private IP addresses that EC2 automatically assigns to the network interface. EC2 uses the value of the `PrivateIpAddress` property as the primary private IP address. If you don't specify that property, EC2 automatically assigns both the primary and secondary private IP addresses.

If you want to specify your own list of private IP addresses, use the `PrivateIpAddresses` property and do not specify this property.

For information about the maximum number of private IP addresses, see Private IP Addresses Per ENI Per Instance Type in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: Integer.

Update requires: No interruption (p. 120).

`SourceDestCheck`

Flag indicating whether traffic to or from the instance is validated.

Required: No

Type: Boolean

Update requires: No interruption (p. 120).

`SubnetId`

The ID of the subnet to associate with the network interface.

Required: Yes

Type: String

Update requires: Replacement (p. 121).

`Tags`

An arbitrary set of tags (key–value pairs) for this network interface.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`PrimaryPrivateIpAddress`

Returns the primary private IP address of the network interface. For example, `10.0.0.192`.

`SecondaryPrivateIpAddresses`

Returns the secondary private IP addresses of the network interface. For example, `["10.0.0.161", "10.0.0.162", "10.0.0.163"]`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Tip
For more NetworkInterface template examples, see Elastic Network Interface (ENI) Template Snippets (p. 345).

Simple Standalone ENI

This is a simple standalone Elastic Network Interface (ENI), using all of the available properties.

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Description" : "Simple Standalone ENI",
   "Resources" : {
      "myENI" : {
         "Type" : "AWS::EC2::NetworkInterface",
         "Properties" : {
            "Tags": [{"Key":"foo","Value":"bar"}],
            "Description": "A nice description.",
            "SourceDestCheck": "false",
            "GroupSet": ["sg-75zzz219"],
            "SubnetId": "subnet-3z648z53",
            "PrivateIpAddress": "10.0.0.16"
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Description: Simple Standalone ENI
Resources:
  myENI:
    Type: AWS::EC2::NetworkInterface
    Properties:
      Tags:
      - Key: foo
        Value: bar
      Description: A nice description.
      SourceDestCheck: 'false'
      GroupSet:
      - sg-75zzz219
      SubnetId: subnet-3z648z53
      PrivateIpAddress: 10.0.0.16
```

ENI on an EC2 instance

This is an example of an ENI on an EC2 instance. In this example, one ENI is added to the instance. If you want to add more than one ENI, you can specify a list for the `NetworkInterface` property. However, you can specify multiple ENIs only if all the ENIs have just private IP addresses (no associated public IP address). If you have an ENI with a public IP address, specify it and then use the `AWS::EC2::NetworkInterfaceAttachment` resource to add additional ENIs.

JSON

```
"Ec2Instance" : {
   "Type" : "AWS::EC2::Instance",
   "Properties" : {
      "ImageId" : { "Fn::FindInMap" : [ "RegionMap", { "Ref" : "AWS::Region" }, "AMI" ]},
      "KeyName" : { "Ref" : "KeyName" },
      "SecurityGroupIds" : [{ "Ref" : "WebSecurityGroup" }],
      "SubnetId" : { "Ref" : "SubnetId" },
      "NetworkInterfaces" : [ {
         "NetworkInterfaceId" : {"Ref" : "controlXface"}, "DeviceIndex" : "1" } ],
      "Tags" : [ {"Key" : "Role", "Value" : "Test Instance"}],
      "UserData" : { "Fn::Base64" : { "Ref" : "WebServerPort" }}
   }
}
```

YAML

```
Ec2Instance:
  Type: AWS::EC2::Instance
  Properties:
    ImageId:
      Fn::FindInMap:
      - RegionMap
      - Ref: AWS::Region
      - AMI
    KeyName:
      Ref: KeyName
    SecurityGroupIds:
    - Ref: WebSecurityGroup
    SubnetId:
      Ref: SubnetId
    NetworkInterfaces:
    - NetworkInterfaceId:
        Ref: controlXface
      DeviceIndex: '1'
```

```
    Tags:
    - Key: Role
      Value: Test Instance
    UserData:
      Fn::Base64:
        Ref: WebServerPort
```

More Info

- NetworkInterface in the *Amazon Elastic Compute Cloud API Reference*

EC2 NetworkInterface Ipv6Addresses

`Ipv6Addresses` is a property of the AWS::EC2::NetworkInterface (p. 1208) resource that specifies an IPv6 address to associate with the network interface.

Syntax

JSON

```
{
   "Ipv6Address" : String
}
```

YAML

```
Ipv6Address: String
```

Properties

`Ipv6Address`

The IPv6 address to associate with the network interface.

Required: Yes

Type: String

Amazon EC2 NetworkInterface PrivateIpAddressSpecification

The `PrivateIpAddressSpecification` type is an embedded property of the AWS::EC2::NetworkInterface (p. 1208) type.

Syntax

JSON

```
{
  "PrivateIpAddress" : String,
  "Primary" : Boolean
}
```

YAML

```
PrivateIpAddress: String
Primary: Boolean
```

Properties

`PrivateIpAddress`

The private IP address of the network interface.

Required: Yes

Type: String

`Primary`

Sets the private IP address as the primary private address. You can set only one primary private IP address. If you don't specify a primary private IP address, Amazon EC2 automatically assigns a primary private IP address.

Required: Yes

Type: Boolean

AWS::EC2::NetworkInterfaceAttachment

Attaches an elastic network interface (ENI) to an Amazon EC2 instance. You can use this resource type to attach additional network interfaces to an instances without interruption.

Topics

- Syntax (p. 1214)
- Properties (p. 1215)
- Return Values (p. 1215)
- Example (p. 1215)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::NetworkInterfaceAttachment",
   "Properties" : {
      "DeleteOnTermination (p. 1215)": Boolean,
      "DeviceIndex (p. 1215)": String,
      "InstanceId (p. 1215)": String,
      "NetworkInterfaceId (p. 1215)": String
   }
}
```

YAML

```
Type: AWS::EC2::NetworkInterfaceAttachment
Properties:
  DeleteOnTermination (p. 1215): Boolean
  DeviceIndex (p. 1215): String
  InstanceId (p. 1215): String
  NetworkInterfaceId (p. 1215): String
```

Properties

`DeleteOnTermination`

Whether to delete the network interface when the instance terminates. By default, this value is set to `True`.

Required: No

Type: Boolean.

Update requires: No interruption (p. 120)

`DeviceIndex`

The network interface's position in the attachment order. For example, the first attached network interface has a `DeviceIndex` of `0`.

Required: Yes.

Type: String.

Update requires: No interruption (p. 120)

`InstanceId`

The ID of the instance to which you will attach the ENI.

Required: Yes.

Type: String.

Update requires: No interruption (p. 120)

`NetworkInterfaceId`

The ID of the ENI that you want to attach.

Required: Yes.

Type: String.

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

Attaching `MyNetworkInterface` to `MyInstance`

JSON

```
"NetworkInterfaceAttachment" : {
    "Type" : "AWS::EC2::NetworkInterfaceAttachment",
        "Properties" : {
            "InstanceId" : {"Ref" : "MyInstance"},
            "NetworkInterfaceId" : {"Ref" : "MyNetworkInterface"},
```

```
            "DeviceIndex" : "1"
        }
}
```

YAML

```
NetworkInterfaceAttachment:
  Type: AWS::EC2::NetworkInterfaceAttachment
  Properties:
    InstanceId:
      Ref: MyInstance
    NetworkInterfaceId:
      Ref: MyNetworkInterface
    DeviceIndex: 1
```

AWS::EC2::NetworkInterfacePermission

The `AWS::EC2::NetworkInterfacePermission` resource specifies a permission for an Amazon EC2 network interface. For example, you can grant an AWS authorized partner account permission to attach the specified network interface to an instance in their account. For more information, see CreateNetworkInterfacePermission and NetworkInterfacePermission in the *Amazon EC2 API Reference*.

Topics

- Syntax (p. 1216)
- Properties (p. 1216)
- Return Values (p. 1217)
- Examples (p. 1217)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::NetworkInterfacePermission",
  "Properties" : {
    "AwsAccountId" : String,
    "NetworkInterfaceId" : String,
    "Permission" : String
  }
}
```

YAML

```
Type: AWS::EC2::NetworkInterfacePermission
Properties:
  AwsAccountId: String
  NetworkInterfaceId: String
  Permission: String
```

Properties

`AwsAccountId`

The AWS account ID.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`NetworkInterfaceId`

The ID of the network interface.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Permission`

The type of permission to grant: `INSTANCE-ATTACH` or `EIP-ASSOCIATE`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::EC2::NetworkInterfacePermission` resource to the intrinsic `Ref` function, the function returns the network interface permission ID. For example, `eni-perm-055663b682ea24b48`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Grant `INSTANCE-ATTACH` Permission

The following example creates a permission (`INSTANCE-ATTACH`) for a specified network interface and AWS account.

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "MyNetworkInterfacePermission": {
            "Type": "AWS::EC2::NetworkInterfacePermission",
            "Properties": {
                "NetworkInterfaceId": "eni-030e3xxx",
                "AwsAccountId": "11111111111",
                "Permission": "INSTANCE-ATTACH"
            }
        }
    },
    "Outputs": {
        "ReferenceId": {
            "Value": {
                "Ref": "MyNetworkInterfacePermission"
            }
```

```
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  MyNetworkInterfacePermission:
    Type: AWS::EC2::NetworkInterfacePermission
    Properties:
      NetworkInterfaceId: eni-030e3xxx
      AwsAccountId: '11111111111'
      Permission: INSTANCE-ATTACH
Outputs:
  ReferenceId:
    Value: !Ref MyNetworkInterfacePermission
```

AWS::EC2::PlacementGroup

The `AWS::EC2::PlacementGroup` resource is a logical grouping of instances within a single Availability Zone (AZ) that enables applications to participate in a low-latency, 10 Gbps network. You create a placement group first, and then you can launch instances in the placement group.

Topics

- Syntax (p. 1218)
- Properties (p. 1218)
- Return Values (p. 1219)
- Example (p. 1219)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::PlacementGroup",
  "Properties" : {
    "Strategy" : String
  }
}
```

YAML

```
Type: AWS::EC2::PlacementGroup
Properties:
  Strategy: String
```

Properties

`Strategy`

The placement strategy, which relates to the instance types that can be added to the placement group. For example, for the `cluster` strategy, you can cluster C4 instance types but not T2 instance

types. For valid values, see CreatePlacementGroup in the *Amazon EC2 API Reference*. By default, AWS CloudFormation sets the value of this property to `cluster`.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a placement group with a `cluster` placement strategy.

JSON

```
"PlacementGroup" : {
  "Type" : "AWS::EC2::PlacementGroup",
  "Properties" : {
    "Strategy" : "cluster"
  }
}
```

YAML

```
PlacementGroup:
  Type: AWS::EC2::PlacementGroup
  Properties:
    Strategy: cluster
```

AWS::EC2::Route

The `AWS::EC2::Route` resource creates a new route in a route table within a VPC. The route's target can be either a gateway attached to the VPC or a NAT instance in the VPC.

Topics

- Syntax (p. 1219)
- Properties (p. 1220)
- Return Values (p. 1222)
- Examples (p. 1222)
- More Info (p. 1223)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::Route",
  "Properties" : {
    "DestinationCidrBlock (p. 1220)" : String,
    "DestinationIpv6CidrBlock" : String,
    "EgressOnlyInternetGatewayId (p. 1220)" : String,
    "GatewayId (p. 1221)" : String,
    "InstanceId (p. 1221)" : String,
    "NatGatewayId" : String,
    "NetworkInterfaceId (p. 1221)" : String,
    "RouteTableId (p. 1221)" : String,
    "VpcPeeringConnectionId" : String
  }
}
```

YAML

```
Type: AWS::EC2::Route
Properties:
  DestinationCidrBlock (p. 1220): String
  DestinationIpv6CidrBlock: String
  EgressOnlyInternetGatewayId (p. 1220): String
  GatewayId (p. 1221): String
  InstanceId (p. 1221): String
  NatGatewayId: String
  NetworkInterfaceId (p. 1221): String
  RouteTableId (p. 1221): String
  VpcPeeringConnectionId: String
```

Properties

`DestinationCidrBlock`

The IPv4 CIDR address block used for the destination match. For example, `0.0.0.0/0`. Routing decisions are based on the most specific match.

Required: Conditional. You must specify the `DestinationCidrBlock` or `DestinationIpv6CidrBlock` property.

Type: String

Update requires: Replacement (p. 121)

`DestinationIpv6CidrBlock`

The IPv6 CIDR address block used for the destination match. For example, `::/0`. Routing decisions are based on the most specific match.

Required: Conditional. You must specify the `DestinationCidrBlock` or `DestinationIpv6CidrBlock` property.

Type: String

Update requires: Replacement (p. 121)

`EgressOnlyInternetGatewayId`

The ID of an egress-only internet gateway that is attached to your VPC (over IPv6 only).

Required: Conditional. You must specify only one of the following properties: `EgressOnlyInternetGatewayId`, `GatewayId`, `InstanceId`, `NatGatewayId`, `NetworkInterfaceId`, or `VpcPeeringConnectionId`. For an example that uses this property, see Amazon EC2 Route with Egress-Only Internet Gateway.

Type: String

Update requires: No interruption (p. 120)

`GatewayId`

The ID of an internet gateway or virtual private gateway that is attached to your VPC. For example: `igw-eaad4883`.

For route entries that specify a gateway, you must specify a dependency on the gateway attachment resource. For more information, see DependsOn Attribute (p. 2275).

Required: Conditional. You must specify only one of the following properties: `EgressOnlyInternetGatewayId`, `GatewayId`, `InstanceId`, `NatGatewayId`, `NetworkInterfaceId`, or `VpcPeeringConnectionId`.

Type: String

Update requires: No interruption (p. 120)

`InstanceId`

The ID of a NAT instance in your VPC. For example, `i-1a2b3c4d`.

Required: Conditional. You must specify only one of the following properties: `EgressOnlyInternetGatewayId`, `GatewayId`, `InstanceId`, `NatGatewayId`, `NetworkInterfaceId`, or `VpcPeeringConnectionId`.

Type: String

Update requires: No interruption (p. 120)

`NatGatewayId`

The ID of a NAT gateway. For example, `nat-0a12bc456789de0fg`.

Required: Conditional. You must specify only one of the following properties: `EgressOnlyInternetGatewayId`, `GatewayId`, `InstanceId`, `NatGatewayId`, `NetworkInterfaceId`, or `VpcPeeringConnectionId`.

Type: String

Update requires: No interruption (p. 120)

`NetworkInterfaceId`

Allows the routing of network interface IDs.

Required: Conditional. You must specify only one of the following properties: `EgressOnlyInternetGatewayId`, `GatewayId`, `InstanceId`, `NatGatewayId`, `NetworkInterfaceId`, or `VpcPeeringConnectionId`.

Type: String

Update requires: No interruption (p. 120)

`RouteTableId`

The ID of the route table (p. 1223) where the route will be added.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`VpcPeeringConnectionId`

The ID of a VPC peering connection.

Required: Conditional. You must specify only one of the following properties: `EgressOnlyInternetGatewayId`, `GatewayId`, `InstanceId`, `NatGatewayId`, `NetworkInterfaceId`, or `VpcPeeringConnectionId`.

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following example creates a route that is added to a gateway.

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myRoute" : {
         "Type" : "AWS::EC2::Route",
         "DependsOn" : "GatewayToInternet",
         "Properties" : {
            "RouteTableId" : { "Ref" : "myRouteTable" },
            "DestinationCidrBlock" : "0.0.0.0/0",
            "GatewayId" : { "Ref" : "myInternetGateway" }
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  myRoute:
    Type: AWS::EC2::Route
    DependsOn: GatewayToInternet
    Properties:
      RouteTableId:
        Ref: myRouteTable
      DestinationCidrBlock: 0.0.0.0/0
      GatewayId:
```

```
        Ref: myInternetGateway
```

More Info

- AWS::EC2::RouteTable (p. 1223)
- CreateRoute in the *Amazon EC2 API Reference*
- Route Tables in the *Amazon VPC User Guide*

AWS::EC2::RouteTable

Creates a new route table within a VPC. After you create a new route table, you can add routes and associate the table with a subnet.

Topics

- Syntax (p. 1223)
- Properties (p. 1223)
- Return Values (p. 1224)
- Examples (p. 1224)
- See Also (p. 1224)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::RouteTable",
   "Properties" : {
      "VpcId (p. 1223)" : String,
      "Tags (p. 1224)" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::EC2::RouteTable
Properties:
  VpcId (p. 1223): String
  Tags (p. 1224):
    - Resource Tag
```

Properties

`VpcId`

The ID of the VPC where the route table will be created.

Example: vpc-11ad4878

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) for this route table.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

Return Values

Ref

When you specify an `AWS::EC2::RouteTable` type as an argument to the `Ref` function, AWS CloudFormation returns the route table ID, such as `rtb-12a34567`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following example snippet uses the VPC ID from a VPC named *myVPC* that was declared elsewhere in the same template.

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myRouteTable" : {
         "Type" : "AWS::EC2::RouteTable",
         "Properties" : {
            "VpcId" : { "Ref" : "myVPC" },
            "Tags" : [ { "Key" : "foo", "Value" : "bar" } ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  myRouteTable:
    Type: AWS::EC2::RouteTable
    Properties:
      VpcId:
        Ref: myVPC
      Tags:
      - Key: foo
        Value: bar
```

- Using Tags in the *Amazon Elastic Compute Cloud User Guide*

AWS::EC2::SecurityGroup

Creates an Amazon EC2 security group. To create a VPC security group, use the VpcId (p. 1226) property.

This type supports updates. For more information about updating stacks, see AWS CloudFormation Stacks Updates (p. 120).

> **Important**
> If you want to cross-reference two security groups in the ingress and egress rules of those security groups, use the AWS::EC2::SecurityGroupEgress (p. 1234) and AWS::EC2::SecurityGroupIngress (p. 1238) resources to define your rules. Do not use the embedded ingress and egress rules in the `AWS::EC2::SecurityGroup`. Doing so creates a circular dependency, which AWS CloudFormation doesn't allow.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::SecurityGroup",
  "Properties" : {
     "GroupName (p. 1225)" : String,
     "GroupDescription (p. 1226)" : String,
     "SecurityGroupEgress (p. 1226)" : [ Security Group Rule, ... ],
     "SecurityGroupIngress (p. 1226)" : [ Security Group Rule, ... ],
     "Tags" :  [ Resource Tag, ... ],
     "VpcId (p. 1226)" : String
  }
}
```

YAML

```
Type: AWS::EC2::SecurityGroup
Properties:
  GroupName (p. 1225): String
  GroupDescription (p. 1226): String
  SecurityGroupEgress (p. 1226):
    - Security Group Rule
  SecurityGroupIngress (p. 1226):
    - Security Group Rule
  Tags:
    - Resource Tag
  VpcId (p. 1226): String
```

Properties

`GroupName`

The name of the security group. For valid values, see the GroupName parameter of the `CreateSecurityGroup` action in the *Amazon EC2 API Reference*.

If you don't specify a `GroupName`, AWS CloudFormation generates a unique physical ID and uses that ID for the group name. For more information, see Name Type (p. 2256).

Important
If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`GroupDescription`

A description of the security group.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SecurityGroupEgress`

A list of Amazon EC2 security group egress rules.

Required: No

Type: List of SecurityGroupRule (p. 1228)

Update requires: No interruption (p. 120)

`SecurityGroupIngress`

A list of Amazon EC2 security group ingress rules.

Required: No

Type: List of SecurityGroupRule (p. 1228)

Update requires: No interruption (p. 120)

`Tags`

The tags that you want to attach to the resource.

Required: No

Type: List of Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`VpcId`

The physical ID of the VPC. You can obtain the physical ID by using a reference to an AWS::EC2::VPC (p. 1285), such as: `{ "Ref" : "myVPC" }`.

For more information about using the `Ref` function, see Ref (p. 2341).

Required: Yes, for VPC security groups without a default VPC

Type: String

Update requires: Replacement (p. 121)

Note
For more information about VPC security groups, see Security Groups in the *Amazon VPC User Guide*.

Return Values

Ref

When you specify an `AWS::EC2::SecurityGroup` type as an argument to the `Ref` function, AWS CloudFormation returns the security group name or the security group ID (for EC2-VPC security groups that are not in a default VPC).

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`GroupId`

The group ID of the specified security group, such as `sg-94b3a1f6`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Define Basic Ingress and Egress Rules

The following example defines a security group with an ingress and egress rule.

JSON

```
"InstanceSecurityGroup" : {
   "Type" : "AWS::EC2::SecurityGroup",
   "Properties" : {
      "GroupDescription" : "Allow http to client host",
      "VpcId" : {"Ref" : "myVPC"},
      "SecurityGroupIngress" : [{
            "IpProtocol" : "tcp",
            "FromPort" : 80,
            "ToPort" : 80,
            "CidrIp" : "0.0.0.0/0"
         }],
      "SecurityGroupEgress" : [{
         "IpProtocol" : "tcp",
         "FromPort" : 80,
         "ToPort" : 80,
         "CidrIp" : "0.0.0.0/0"
      }]
   }
}
```

YAML

```
InstanceSecurityGroup:
  Type: AWS::EC2::SecurityGroup
  Properties:
    GroupDescription: Allow http to client host
    VpcId:
      Ref: myVPC
    SecurityGroupIngress:
    - IpProtocol: tcp
      FromPort: 80
```

```
      ToPort: 80
      CidrIp: 0.0.0.0/0
    SecurityGroupEgress:
    - IpProtocol: tcp
      FromPort: 80
      ToPort: 80
      CidrIp: 0.0.0.0/0
```

Remove Default Rule

When you create a VPC security group, Amazon EC2 creates a default egress rule that allows egress traffic on all ports and IP protocols to any location. The default rule is removed only when you specify one or more egress rules. If you want to remove the default rule and limit egress traffic to just the localhost (`127.0.0.1/32`), use the following example.

JSON

```
"sgwithoutegress": {
  "Type": "AWS::EC2::SecurityGroup",
  "Properties": {
    "GroupDescription": "Limits security group egress traffic",
    "SecurityGroupEgress": [
      {
        "CidrIp": "127.0.0.1/32",
        "IpProtocol": "-1"
      }
    ],
    "VpcId": { "Ref": "myVPC"}
  }
}
```

YAML

```
sgwithoutegress:
  Type: AWS::EC2::SecurityGroup
  Properties:
    GroupDescription: Limits security group egress traffic
    SecurityGroupEgress:
    - CidrIp: 127.0.0.1/32
      IpProtocol: "-1"
    VpcId:
      Ref: myVPC
```

More Info

- Using Security Groups in the *Amazon EC2 User Guide for Linux Instances*.
- Security Groups in the *Amazon VPC User Guide*.

EC2 Security Group Rule Property Type

The EC2 Security Group Rule is an embedded property of the AWS::EC2::SecurityGroup (p. 1225) type.

Syntax SecurityGroupIngress

JSON

```
{
  "CidrIp (p. 1229)" : String,
  "CidrIpv6 (p. 1229)" : String,
```

```
  "Description (p. 1230)" : String,
  "FromPort (p. 1230)" : Integer,
  "IpProtocol (p. 1230)" : String,
  "SourceSecurityGroupId (p. 1230)" : String,
  "SourceSecurityGroupName (p. 1230)" : String,
  "SourceSecurityGroupOwnerId (p. 1231)" : String,
  "ToPort (p. 1231)" : Integer
}
```

YAML

```
CidrIp (p. 1229): String
CidrIpv6 (p. 1229): String
Description (p. 1230): String
FromPort (p. 1230): Integer
IpProtocol (p. 1230): String
SourceSecurityGroupId (p. 1230): String
SourceSecurityGroupName (p. 1230): String
SourceSecurityGroupOwnerId (p. 1231): String
ToPort (p. 1231): Integer
```

Syntax SecurityGroupEgress

JSON

```
{
  "CidrIp (p. 1229)" : String,
  "CidrIpv6 (p. 1229)" : String,
  "Description (p. 1230)" : String,
  "DestinationPrefixListId (p. 1230)" : String,
  "DestinationSecurityGroupId (p. 1230)" : String,
  "FromPort (p. 1230)" : Integer,
  "IpProtocol (p. 1230)" : String,
  "ToPort (p. 1231)" : Integer
}
```

YAML

```
CidrIp (p. 1229): String
CidrIpv6 (p. 1229): String
Description (p. 1230): String
DestinationPrefixListId (p. 1230): String
DestinationSecurityGroupId (p. 1230): String
FromPort (p. 1230): Integer
IpProtocol (p. 1230): String
ToPort (p. 1231): Integer
```

Properties

`CidrIp`

Specifies an IPv4 CIDR range.

Required: Conditional. You must specify only one of the following properties: `CidrIp`, `CidrIpv6`, `DestinationPrefixListId`, `DestinationSecurityGroupId`, or `SourceSecurityGroupId`.

Type: String

`CidrIpv6`

Specifies an IPv6 CIDR range.

Required: Conditional. You must specify only one of the following properties: `CidrIp`, `CidrIpv6`, `DestinationPrefixListId`, `DestinationSecurityGroupId`, or `SourceSecurityGroupId`.

Type: String

`Description`

Description of the security group rule.

Type: String

`DestinationPrefixListId` (SecurityGroupEgress only)

The AWS service prefix of an Amazon VPC endpoint. For more information, see VPC Endpoints in the *Amazon VPC User Guide*.

Required: Conditional. You must specify only one of the following properties: `CidrIp`, `CidrIpv6`, `DestinationPrefixListId`, `DestinationSecurityGroupId`, or `SourceSecurityGroupId`.

Type: String

`DestinationSecurityGroupId` (SecurityGroupEgress only)

Specifies the GroupId of the destination Amazon VPC security group.

Required: Conditional. You must specify only one of the following properties: `CidrIp`, `CidrIpv6`, `DestinationPrefixListId`, `DestinationSecurityGroupId`, or `SourceSecurityGroupId`.

Type: String

`FromPort`

The start of port range for the TCP and UDP protocols, or an ICMP type number. An ICMP type number of -1 indicates a wildcard (i.e., any ICMP type number).

Required: No

Type: Integer

`IpProtocol`

An IP protocol name or number. For valid values, go to the IpProtocol parameter in AuthorizeSecurityGroupIngress

Required: Yes

Type: String

`SourceSecurityGroupId` (SecurityGroupIngress only)

For VPC security groups only. Specifies the ID of the Amazon EC2 Security Group to allow access. You can use the `Ref` intrinsic function to refer to the logical ID of a security group defined in the same template.

Required: Conditional. You must specify only one of the following properties: `CidrIp`, `CidrIpv6`, `DestinationPrefixListId`, `DestinationSecurityGroupId`, or `SourceSecurityGroupId`.

Type: String

`SourceSecurityGroupName` (SecurityGroupIngress only)

For non-VPC security groups only. Specifies the name of the Amazon EC2 Security Group to use for access. You can use the `Ref` intrinsic function to refer to the logical name of a security group that is defined in the same template.

Required: Conditional. If you specify `CidrIp`, do not specify `SourceSecurityGroupName`.

Type: String

`SourceSecurityGroupOwnerId` (SecurityGroupIngress only)

Specifies the AWS Account ID of the owner of the Amazon EC2 Security Group that is specified in the `SourceSecurityGroupName` property.

Required: Conditional. If you specify `SourceSecurityGroupName` and that security group is owned by a different account than the account creating the stack, you must specify the `SourceSecurityGroupOwnerId`; otherwise, this property is optional.

Type: String

`ToPort`

The end of port range for the TCP and UDP protocols, or an ICMP code. An ICMP code of -1 indicates a wildcard (i.e., any ICMP code).

Required: No

Type: Integer

Examples

Security Group with CidrIp

JSON

```
"InstanceSecurityGroup" : {
   "Type" : "AWS::EC2::SecurityGroup",
   "Properties" : {
      "GroupDescription" : "Enable SSH access via port 22",
      "SecurityGroupIngress" : [ {
         "IpProtocol" : "tcp",
         "FromPort" : 22,
         "ToPort" : 22,
         "CidrIp" : "0.0.0.0/0"
      } ]
   }
}
```

YAML

```
InstanceSecurityGroup:
  Type: AWS::EC2::SecurityGroup
  Properties:
    GroupDescription: "Enable SSH access via port 22"
    SecurityGroupIngress:
      -
        IpProtocol: "tcp"
        FromPort: 22
        ToPort: 22
        CidrIp: "0.0.0.0/0"
```

Security Group with Security Group Id

JSON

```
"InstanceSecurityGroup" : {
   "Type" : "AWS::EC2::SecurityGroup",
   "Properties" : {
      "GroupDescription" : "Enable HTTP access on the configured port",
      "VpcId" : { "Ref" : "VpcId" },
```

```
      "SecurityGroupIngress" : [ {
         "IpProtocol" : "tcp",
         "FromPort" : { "Ref" : "WebServerPort" },
         "ToPort" : { "Ref" : "WebServerPort" },
         "SourceSecurityGroupId" : { "Ref" : "LoadBalancerSecurityGroup" }
      } ]
   }
}
```

YAML

```
InstanceSecurityGroup:
  Type: AWS::EC2::SecurityGroup
  Properties:
    GroupDescription: "Enable HTTP access on the configured port"
    VpcId:
      Ref: "VpcId"
    SecurityGroupIngress:
      -
        IpProtocol: "tcp"
        FromPort:
          Ref: "WebServerPort"
        ToPort:
          Ref: "WebServerPort"
        SourceSecurityGroupId:
          Ref: "LoadBalancerSecurityGroup"
```

Security Group with Multiple Ingress Rules

This snippet grants SSH access with CidrIp, and HTTP access with `SourceSecurityGroupName`. `Fn::GetAtt` is used to derive the values for `SourceSecurityGroupName` and `SourceSecurityGroupOwnerId` from the elastic load balancer.

JSON

```
"ElasticLoadBalancer" : {
   "Type" : "AWS::ElasticLoadBalancing::LoadBalancer",
   "Properties" : {
      "AvailabilityZones" : { "Fn::GetAZs" : "" },
      "Listeners" : [ {
         "LoadBalancerPort" : "80",
         "InstancePort" : { "Ref" : "WebServerPort" },
         "Protocol" : "HTTP"
      } ],
      "HealthCheck" : {
         "Target" : { "Fn::Join" : [ "", ["HTTP:", { "Ref" : "WebServerPort" }, "/"]]},
         "HealthyThreshold" : "3",
         "UnhealthyThreshold" : "5",
         "Interval" : "30",
         "Timeout" : "5"
      }
   }
},

"InstanceSecurityGroup" : {
   "Type" : "AWS::EC2::SecurityGroup",
   "Properties" : {
      "GroupDescription" : "Allow SSH access from all IP addresses and HTTP from the load
 balancer only",
      "SecurityGroupIngress" : [ {
         "IpProtocol" : "tcp",
         "FromPort" : 22,
         "ToPort" : 22,
```

```
         "CidrIp" : "0.0.0.0/0"
      }, {
         "IpProtocol" : "tcp",
         "FromPort" : { "Ref" : "WebServerPort" },
         "ToPort" : { "Ref" : "WebServerPort" },
         "SourceSecurityGroupOwnerId" : {"Fn::GetAtt" : ["ElasticLoadBalancer",
 "SourceSecurityGroup.OwnerAlias"]},
         "SourceSecurityGroupName" : {"Fn::GetAtt" : ["ElasticLoadBalancer",
 "SourceSecurityGroup.GroupName"]}
      } ]
   }
}
```

YAML

```
ElasticLoadBalancer:
  Type: AWS::ElasticLoadBalancing::LoadBalancer
  Properties:
    AvailabilityZones:
      Fn::GetAZs: ""
    Listeners:
      -
        LoadBalancerPort: "80"
        InstancePort:
          Ref: "WebServerPort"
        Protocol: "HTTP"
    HealthCheck:
      Target:
        Fn::Join:
          - ""
          -
            - "HTTP:"
            -
              Ref: "WebServerPort"
            - "/"
      HealthyThreshold: "3"
      UnhealthyThreshold: "5"
      Interval: "30"
      Timeout: "5"
InstanceSecurityGroup:
  Type: AWS::EC2::SecurityGroup
  Properties:
    GroupDescription: "Allow SSH access from all IP addresses and HTTP from the load
 balancer only"
    SecurityGroupIngress:
      -
        IpProtocol: "tcp"
        FromPort: 22
        ToPort: 22
        CidrIp: "0.0.0.0/0"
      -
        IpProtocol: "tcp"
        FromPort:
          Ref: "WebServerPort"
        ToPort:
          Ref: "WebServerPort"
        SourceSecurityGroupOwnerId:
          Fn::GetAtt:
            - "ElasticLoadBalancer"
            - "SourceSecurityGroup.OwnerAlias"
        SourceSecurityGroupName:
          Fn::GetAtt:
            - "ElasticLoadBalancer"
            - "SourceSecurityGroup.GroupName"
```

See Also

- Amazon EC2 Security Groups in the *Amazon EC2 User Guide*

AWS::EC2::SecurityGroupEgress

The `AWS::EC2::SecurityGroupEgress` resource adds an egress rule to an Amazon VPC security group. When you use the `AWS::EC2::SecurityGroupEgress` resource, the default rule is removed from the security group.

> **Important**
> Use `AWS::EC2::SecurityGroupIngress` and `AWS::EC2::SecurityGroupEgress` only when necessary, typically to allow security groups to reference each other in ingress and egress rules. Otherwise, use the embedded ingress and egress rules of AWS::EC2::SecurityGroup (p. 1225). For more information, see Amazon EC2 Security Groups.

Topics

- Syntax (p. 1234)
- Properties (p. 1235)
- Return Values (p. 1236)
- VPC Security Groups Example (p. 1236)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::SecurityGroupEgress",

YAML

```
Type: AWS::EC2::SecurityGroupEgress
Properties:
  CidrIp: String
  CidrIpv6: String
  Description: String
  DestinationPrefixListId: String
  DestinationSecurityGroupId:  String
  FromPort: Integer
  GroupId: String
  IpProtocol: String
  ToPort: Integer
```

Properties

For more information about adding egress rules to VPC security groups, go to AuthorizeSecurityGroupEgress in the *Amazon EC2 API Reference*.

> **Note**
> If you change this resource's logical ID, you must also update a property value in order to trigger an update for this resource.

`CidrIp`

An IPv4 CIDR range.

Required: Conditional. You must specify a destination security group (`DestinationPrefixListId` or `DestinationSecurityGroupId`) or a CIDR range (`CidrIp` or `CidrIpv6`).

Type: String

Update requires: Replacement (p. 121)

`CidrIpv6`

An IPv6 CIDR range.

Type: String

Required: Conditional. You must specify a destination security group (`DestinationPrefixListId` or `DestinationSecurityGroupId`) or a CIDR range (`CidrIp` or `CidrIpv6`).

Update requires: Replacement (p. 121)

`Description`

Description of the egress rule.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DestinationPrefixListId`

The AWS service prefix of an Amazon VPC endpoint. For more information, see VPC Endpoints in the *Amazon VPC User Guide*.

Required: Conditional. You must specify a destination security group (`DestinationPrefixListId` or `DestinationSecurityGroupId`) or a CIDR range (`CidrIp` or `CidrIpv6`).

Type: String

Update requires: Replacement (p. 121)

`DestinationSecurityGroupId`

Specifies the group ID of the destination Amazon VPC security group.

Required: Conditional. You must specify a destination security group (`DestinationPrefixListId` or `DestinationSecurityGroupId`) or a CIDR range (`CidrIp` or `CidrIpv6`).

Type: String

Update requires: Replacement (p. 121)

`FromPort`

Start of port range for the TCP and UDP protocols, or an ICMP type number. If you specify `icmp` for the `IpProtocol` property, you can specify -1 as a wildcard (i.e., any ICMP type number).

Required: Yes

Type: Integer

Update requires: Replacement (p. 121)

`GroupId`

ID of the Amazon VPC security group to modify. This value can be a reference to an AWS::EC2::SecurityGroup (p. 1225) resource that has a valid `VpcId` property or the ID of an existing Amazon VPC security group.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`IpProtocol`

IP protocol name or number. For valid values, see the IpProtocol parameter in AuthorizeSecurityGroupIngress

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ToPort`

End of port range for the TCP and UDP protocols, or an ICMP code. If you specify `icmp` for the `IpProtocol` property, you can specify -1 as a wildcard (i.e., any ICMP code).

Required: Yes

Type: Integer

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

VPC Security Groups Example

In some cases, you might have an originating (source) security group to which you want to add an outbound rule that allows traffic to a destination (target) security group. The target security group also needs an inbound rule that allows traffic from the source security group. Note that you cannot use the

`Ref` function to specify the outbound and inbound rules for each security group. Doing so creates a circular dependency; you cannot have two resources that depend on each other. Instead, use the egress and ingress resources to declare these outbound and inbound rules, as shown in the following template snippet.

JSON

AWS::EC2::SecurityGroupIngress

The `AWS::EC2::SecurityGroupIngress` resource adds an ingress rule to an Amazon EC2 or Amazon VPC security group.

> **Important**
> Use `AWS::EC2::SecurityGroupIngress` and `AWS::EC2::SecurityGroupEgress` only when necessary, typically to allow security groups to reference each other in ingress and egress rules. Otherwise, use the embedded ingress and egress rules of AWS::EC2::SecurityGroup (p. 1225). For more information, see Amazon EC2 Security Groups.

Topics

- Syntax (p. 1239)
- Properties (p. 1239)
- Examples (p. 1241)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::SecurityGroupIngress",
  "Properties" : {
    "CidrIp" : String,
    "CidrIpv6" : String,
    "Description" : String,
    "FromPort" : Integer,
    "GroupId" : String,
    "GroupName" : String,
    "IpProtocol" : String,
    "SourceSecurityGroupName" : String,
    "SourceSecurityGroupId" : String,
    "SourceSecurityGroupOwnerId" : String,
    "ToPort" : Integer
  }
}
```

YAML

```
Type: AWS::EC2::SecurityGroupIngress
Properties:
  CidrIp: String
  CidrIpv6: String
  Description: String
  FromPort: Integer
  GroupId: String
  GroupName: String
  IpProtocol: String
  SourceSecurityGroupName: String
  SourceSecurityGroupId: String
  SourceSecurityGroupOwnerId: String
  ToPort: Integer
```

Properties

For more information about adding ingress rules to Amazon EC2 or VPC security groups, see AuthorizeSecurityGroupIngress in the *Amazon EC2 API Reference*.

> **Note**
> If you change this resource's logical ID, you must also update a property value in order to trigger an update for this resource.

`CidrIp`

An IPv4 CIDR range.

For an overview of CIDR ranges, go to the Wikipedia Tutorial.

Type: String

Required: Conditional. You must specify a source security group (`SourceSecurityGroupName` or `SourceSecurityGroupId`) or a CIDR range (`CidrIp` or `CidrIpv6`).

Update requires: Replacement (p. 121)

`CidrIpv6`

An IPv6 CIDR range.

Type: String

Required: Conditional. You must specify a source security group (`SourceSecurityGroupName` or `SourceSecurityGroupId`) or a CIDR range (`CidrIp` or `CidrIpv6`).

Update requires: Replacement (p. 121)

`Description`

Description of the ingress rule.

Required: No

Type: String

Update requires: No interruption (p. 120)

`FromPort`

Start of port range for the TCP and UDP protocols, or an ICMP type number. If you specify `icmp` for the `IpProtocol` property, you can specify -1 as a wildcard (i.e., any ICMP type number).

Type: Integer

Required: Yes, for ICMP and any protocol that uses ports.

Update requires: Replacement (p. 121)

`GroupId`

ID of the Amazon EC2 or VPC security group to modify. The group must belong to your account.

Type: String

Required: Conditional. You must specify the `GroupName` property or the `GroupId` property. For security groups that are in a VPC, you must use the `GroupId` property. For example, EC2-VPC accounts must use the `GroupId` property.

Update requires: Replacement (p. 121)

`GroupName`

Name of the Amazon EC2 security group (non-VPC security group) to modify. This value can be a reference to an AWS::EC2::SecurityGroup (p. 1225) resource or the name of an existing Amazon EC2 security group.

Type: String

Required: Conditional. You must specify the `GroupName` property or the `GroupId` property. For security groups that are in a VPC, you must use the `GroupId` property. For example, EC2-VPC accounts must use the `GroupId` property.

Update requires: Replacement (p. 121)

`IpProtocol`

IP protocol name or number. For valid values, see the IpProtocol parameter in AuthorizeSecurityGroupIngress

Type: String

Required: Yes

Update requires: Replacement (p. 121)

`SourceSecurityGroupId`

Specifies the ID of the source security group or uses the `Ref` intrinsic function to refer to the logical ID of a security group defined in the same template.

Type: String

Required: Conditional. You must specify a source security group (`SourceSecurityGroupName` or `SourceSecurityGroupId`) or a CIDR range (`CidrIp` or `CidrIpv6`).

Update requires: Replacement (p. 121)

`SourceSecurityGroupName`

Specifies the name of the Amazon EC2 security group (non-VPC security group) to allow access or use the `Ref` intrinsic function to refer to the logical ID of a security group defined in the same template. For instances in a VPC, specify the `SourceSecurityGroupId` property.

Type: String

Required: Conditional. You must specify a source security group (`SourceSecurityGroupName` or `SourceSecurityGroupId`) or a CIDR range (`CidrIp` or `CidrIpv6`).

Update requires: Replacement (p. 121)

`SourceSecurityGroupOwnerId`

Specifies the AWS Account ID of the owner of the Amazon EC2 security group specified in the `SourceSecurityGroupName` property.

Type: String

Required: Conditional. If you specify `SourceSecurityGroupName` and that security group is owned by a different account than the account creating the stack, you must specify the `SourceSecurityGroupOwnerId`; otherwise, this property is optional.

Update requires: Replacement (p. 121)

`ToPort`

End of port range for the TCP and UDP protocols, or an ICMP code. If you specify `icmp` for the `IpProtocol` property, you can specify -1 as a wildcard (i.e., any ICMP code).

Type: Integer

Required: Yes, for ICMP and any protocol that uses ports.

Update requires: Replacement (p. 121)

Examples

EC2 Security Group and Ingress Rule

To create an Amazon EC2 (non-VPC) security group and an ingress rule, use the `SourceSecurityGroupName` property in the ingress rule.

The following template snippet creates an EC2 security group with an ingress rule that allows incoming traffic on port 80 from any other host in the security group. The snippet uses the intrinsic function `Ref` (p. 2341) to specify the value for `SourceSecurityGroupName`.

```

Allow Traffic from a Security Group in a Peered VPC

Like the previous example, the following example allows one-way traffic from an originating (source) security group to a destination (target) security group. However, in this example the security groups are in peered VPCs across AWS accounts. You might want to allow cross-account traffic if, for example, you create a security scanning resource in one AWS account that you'll use to run diagnostics in another account. This example adds an ingress rule to a target VPC security group that allows incoming traffic from a source security group in a different AWS account. Note that the source security group also needs an egress rule that allows outgoing traffic to the target security group. Because the source security group is in a different account, the following example doesn't use the Ref function to reference the source security group ID but instead directly specifies the security group ID `sg-12345678`.

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
```

```
        "TargetSG": {
            "Type": "AWS::EC2::SecurityGroup",
            "Properties": {
                "VpcId": "vpc-1a2b3c4d",
                "GroupDescription": "Security group allowing ingress for security scanners"
            }
        },
        "InboundRule": {
            "Type": "AWS::EC2::SecurityGroupIngress",
            "Properties": {
                "GroupId": {
                    "Fn::GetAtt": [
                        "TargetSG",
                        "GroupId"
                    ]
                },
                "IpProtocol": "tcp",
                "FromPort": "80",
                "ToPort": "80",
                "SourceSecurityGroupId": "sg-12345678",
                "SourceSecurityGroupOwnerId": "123456789012"
            }
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  TargetSG:

      SourceSecurityGroupOwnerId: '123456789012'
```

Allow Ping Requests

To allow ping requests, add the ICMP protocol type and specify `8` (echo request) for the ICMP type and either `0` or `-1` (all) for the ICMP code.

JSON

```
"SGPing" : {
  "Type" : "AWS::EC2::SecurityGroup",
  "DependsOn": "VPC",
  "Properties" : {
    "GroupDescription" : "SG to test ping",
    "VpcId" : {"Ref" : "VPC"},
    "SecurityGroupIngress" : [
      { "IpProtocol" : "tcp", "FromPort" : 22, "ToPort" : 22, "CidrIp" : "10.0.0.0/24" },
      { "IpProtocol" : "icmp", "FromPort" : 8, "ToPort" : -1, "CidrIp" : "10.0.0.0/24" }
    ]
  }
```

```
}
```

YAML

```
SGPing:
  Type: AWS::EC2::SecurityGroup
  DependsOn: VPC
  Properties:
    GroupDescription: SG to test ping
    VpcId:
      Ref: VPC
    SecurityGroupIngress:
    - IpProtocol: tcp
      FromPort: 22
      ToPort: 22
      CidrIp: 10.0.0.0/24
    - IpProtocol: icmp
      FromPort: 8
      ToPort: -1
      CidrIp: 10.0.0.0/24
```

AWS::EC2::SpotFleet

The `AWS::EC2::SpotFleet` resource creates a request for a collection of Spot instances. The Spot fleet attempts to launch the number of Spot instances to meet the target capacity that you specified. For more information, see Spot Instances in the *Amazon EC2 User Guide for Linux Instances*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::SpotFleet",
  "Properties" : {
    "SpotFleetRequestConfigData" : SpotFleetRequestConfigData
  }
}
```

YAML

```
Type: AWS::EC2::SpotFleet
Properties:
  SpotFleetRequestConfigData:
    SpotFleetRequestConfigData
```

Properties

`SpotFleetRequestConfigData`

The configuration for a Spot fleet request.

Required: Yes

Type: Amazon EC2 SpotFleet SpotFleetRequestConfigData (p. 1265)

Update requires: Some interruptions (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a Spot fleet with two launch specifications. The weighted capacities are the same, so Amazon EC2 launches the same number of instances for each specification. For more information, see How Spot Fleet Works in the *Amazon EC2 User Guide for Linux Instances*.

JSON

```
"SpotFleet": {
  "Type": "AWS::EC2::SpotFleet",
  "Properties": {
    "SpotFleetRequestConfigData": {

Amazon Elastic Compute Cloud SpotFleet LaunchSpecifications

`LaunchSpecifications` is a property of the Amazon EC2 SpotFleet SpotFleetRequestConfigData (p. 1265) property that defines the launch specifications for the Spot fleet request.

Syntax

JSON

```
{
  "BlockDeviceMappings" : [ BlockDeviceMapping, ... ],
  "EbsOptimized" : Boolean,
```

```
  "IamInstanceProfile" : IamInstanceProfile,
  "ImageId" : String,
  "InstanceType" : String,
  "KernelId" : String,
  "KeyName" : String,
  "Monitoring" : Boolean,
  "NetworkInterfaces" : [ NetworkInterface, ... ],
  "Placement" : Placement,
  "RamdiskId" : String,
  "SecurityGroups" : [ SecurityGroup, ... ],
  "SpotPrice" : String,
  "SubnetId" : String,
  "TagSpecifications" : SpotFleetTagSpecification,
  "UserData" : String,
  "WeightedCapacity" : Number
}
```

YAML

```
BlockDeviceMappings:
  - BlockDeviceMapping
EbsOptimized: Boolean
IamInstanceProfile:
  IamInstanceProfile
ImageId: String
InstanceType: String
KernelId: String
KeyName: String
Monitoring: Boolean
NetworkInterfaces:
  - NetworkInterface
Placement:
  Placement
RamdiskId: String
SecurityGroups:
  - SecurityGroup
SpotPrice: String
SubnetId: String
TagSpecifications:
  - SpotFleetTagSpecification
UserData: String
WeightedCapacity: Number
```

Properties

`BlockDeviceMappings`

Defines the block devices that are mapped to the Spot instances.

Required: No

Type: List of Amazon Elastic Compute Cloud SpotFleet BlockDeviceMappings (p. 1252)

`EbsOptimized`

Indicates whether the instances are optimized for Amazon Elastic Block Store (Amazon EBS) I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. This optimization isn't available with all instance types. Additional usage charges apply when you use an Amazon EBS-optimized instance.

Required: No

Type: Boolean

`IamInstanceProfile`

Defines the AWS Identity and Access Management (IAM) instance profile to associate with the instances.

Required: No

Type: Amazon Elastic Compute Cloud SpotFleet IamInstanceProfile (p. 1256)

`ImageId`

The unique ID of the Amazon Machine Image (AMI) to launch on the instances.

Required: Yes

Type: String

`InstanceType`

Specifies the instance type of the EC2 instances.

Required: Yes

Type: String

`KernelId`

The ID of the kernel that is associated with the Amazon Elastic Compute Cloud (Amazon EC2) AMI.

Required: No

Type: String

`KeyName`

An Amazon EC2 key pair to associate with the instances.

Required: No

Type: String

`Monitoring`

Enable or disable monitoring for the instances.

Required: No

Type: Amazon EC2 SpotFleet Monitoring (p. 1260)

`NetworkInterfaces`

The network interfaces to associate with the instances.

Required: No

Type: List of Amazon Elastic Compute Cloud SpotFleet NetworkInterfaces (p. 1260)

`Placement`

Defines a placement group, which is a logical grouping of instances within a single Availability Zone (AZ).

Required: No

Type: Amazon Elastic Compute Cloud SpotFleet Placement (p. 1263)

`RamdiskId`

The ID of the RAM disk to select. Some kernels require additional drivers at launch. Check the kernel requirements for information about whether you need to specify a RAM disk. To find kernel requirements, refer to the AWS Resource Center and search for the kernel ID.

Required: No

Type: String

`SecurityGroups`

One or more security group IDs to associate with the instances.

Required: No

Type: List of Amazon Elastic Compute Cloud SpotFleet SecurityGroups (p. 1264)

`SpotPrice`

The bid price per unit hour for the specified instance type. If you don't specify a value, Amazon EC2 uses the Spot bid price for the fleet. For more information, see How Spot Fleet Works in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: String

`SubnetId`

The ID of the subnet in which to launch the instances.

Required: No

Type: String

`TagSpecifications`

The tags to apply during creation.

Required: No

Type: List of SpotFleetTagSpecification (p. 1268)

`UserData`

Base64-encoded MIME user data that instances use when starting up.

Required: No

Type: String

`WeightedCapacity`

The number of units provided by the specified instance type. These units are the same units that you chose to set the target capacity in terms of instances or a performance characteristic, such as vCPUs, memory, or I/O. For more information, see How Spot Fleet Works in the *Amazon EC2 User Guide for Linux Instances*.

If the target capacity divided by this value is not a whole number, Amazon EC2 rounds the number of instances to the next whole number.

Required: No

Type: Number

Amazon Elastic Compute Cloud SpotFleet BlockDeviceMappings

`BlockDeviceMappings` is a property of the Amazon Elastic Compute Cloud SpotFleet LaunchSpecifications (p. 1248) property that defines the block devices that are mapped to an instance.

Syntax

JSON

```
{
  "DeviceName" : String,
  "Ebs" : EBSBlockDevice,
  "NoDevice" : Boolean,
  "VirtualName" : String
}
```

YAML

```
DeviceName: String
Ebs:
  EBSBlockDevice
NoDevice: Boolean
VirtualName: String
```

Properties

`DeviceName`

The name of the device within the EC2 instance, such as `/dev/dsh` or `xvdh`.

Required: Yes

Type: String

`Ebs`

The Amazon Elastic Block Store (Amazon EBS) volume information.

Required: Conditional You can specify either the `VirtualName` or `Ebs`, but not both.

Type: Amazon Elastic Compute Cloud SpotFleet Ebs (p. 1254)

`NoDevice`

Suppresses the specified device that is included in the block device mapping of the Amazon Machine Image (AMI).

Required: No

Type: Boolean

`VirtualName`

The name of the virtual device. The name must be in the form `ephemeralX` where *X* is a number equal to or greater than zero (0), for example, `ephemeral0`.

Required: Conditional You can specify either the `VirtualName` or `Ebs`, but not both.

Type: String

Amazon EC2 SpotFleet ClassicLoadBalancer

The `ClassicLoadBalancer` property type specifies a Classic Load Balancer.

`ClassicLoadBalancer` is a property of the Amazon EC2 SpotFleet ClassicLoadBalancersConfig (p. 1253) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Name" : String
}
```

YAML

```
Name: String
```

Properties

`Name`

The name of the load balancer.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

See Also

- ClassicLoadBalancer in the *Amazon EC2 API Reference*

Amazon EC2 SpotFleet ClassicLoadBalancersConfig

The `ClassicLoadBalancersConfig` property type specifies the Classic Load Balancers to attach to a Spot Fleet. Spot Fleet registers the running Spot Instances with these Classic Load Balancers.

`ClassicLoadBalancersConfig` is a property of the Amazon EC2 SpotFleet LoadBalancersConfig (p. 1259) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ClassicLoadBalancers" : [ ClassicLoadBalancer (p. 1253), ... ]
```

```
}
```

YAML

```
ClassicLoadBalancers
  - ClassicLoadBalancer (p. 1253)
```

Properties

`ClassicLoadBalancers`

One or more Classic Load Balancers to attach to the Spot Fleet. Duplicates not allowed. For property constraints, see ClassicLoadBalancersConfig in the *Amazon EC2 API Reference*.

Required: Yes

Type: List of Amazon EC2 SpotFleet ClassicLoadBalancer (p. 1253)

Update requires: No interruption (p. 120)

See Also

- ClassicLoadBalancersConfig in the *Amazon EC2 API Reference*

Amazon Elastic Compute Cloud SpotFleet Ebs

`Ebs` is a property of the Amazon Elastic Compute Cloud SpotFleet BlockDeviceMappings (p. 1252) property that defines a block device for an Amazon Elastic Block Store (Amazon EBS) volume.

Syntax

JSON

```
{
  "DeleteOnTermination" : Boolean,
  "Encrypted" : Boolean,
  "Iops" : Integer,
  "SnapshotId" : String,
  "VolumeSize" : Integer,
  "VolumeType" : String
}
```

YAML

```
DeleteOnTermination: Boolean
Encrypted: Boolean
Iops: Integer
SnapshotId: String
VolumeSize: Integer
VolumeType: String
```

Properties

`DeleteOnTermination`

Indicates whether to delete the volume when the instance is terminated.

Required: No

Type: Boolean

`Encrypted`

Indicates whether the EBS volume is encrypted. Encrypted Amazon EBS volumes can be attached only to instances that support Amazon EBS encryption.

Required: No

Type: Boolean

`Iops`

The number of I/O operations per second (IOPS) that the volume supports. For more information, see Iops for the `EbsBlockDevice` action in the *Amazon EC2 API Reference*.

Required: No

Type: Integer

`SnapshotId`

The snapshot ID of the volume that you want to use. If you specify both the `SnapshotId` and `VolumeSize` properties, `VolumeSize` must be equal to or greater than the size of the snapshot.

Required: No

Type: String

`VolumeSize`

The volume size, in Gibibytes (GiB). If you specify both the `SnapshotId` and `VolumeSize` properties, `VolumeSize` must be equal to or greater than the size of the snapshot. For more information about specifying the volume size, see VolumeSize for the `EbsBlockDevice` action in the *Amazon EC2 API Reference*.

Required: No

Type: Integer

`VolumeType`

The volume type. For more information about specifying the volume type, see VolumeType for the `EbsBlockDevice` action in the *Amazon EC2 API Reference*.

Required: No

Type: String

Amazon Elastic Compute Cloud SpotFleet FleetLaunchTemplateSpecification

`FleetLaunchTemplateSpecification` is a property of the Amazon EC2 SpotFleet SpotFleetRequestConfigData (p. 1265) property that describes a launch template.

Syntax

JSON

```
{
  "LaunchTemplateId" : String,
  "LaunchTemplateName" : String,
```

```
  "Version" : String
}
```

YAML

```
LaunchTemplateId: String
LaunchTemplateName: String
Version: String
```

Properties

`LaunchTemplateId`

The ID of the launch template. You must specify either a template ID or a template name.

Required: No

Type: String

Update requires: No interruption (p. 120)

`LaunchTemplateName`

The name of the launch template. You must specify either a template name or a template ID.

Minimum length of 3. Maximum length of 128. Names must match the following pattern: `[a-zA-Z0-9\(\)\.-/_]+`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Version`

The version number. AWS CloudFormation does not support specifying `$Latest` or `$Default` for the template version number.

Minimum length of 1. Maximum length of 255. Versions must fit the following pattern:

[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Elastic Compute Cloud SpotFleet IamInstanceProfile

`IamInstanceProfile` is a property of the Amazon Elastic Compute Cloud SpotFleet LaunchSpecifications (p. 1248) property that specifies the IAM instance profile to associate with the instances.

Syntax

JSON

```
{
```

```
  "Arn" : String
}
```

YAML

```
Arn: String
```

Properties

`Arn`

The Amazon Resource Name (ARN) of the instance profile to associate with the instances. The instance profile contains the IAM role that is associated with the instances.

Required: No

Type: String

Amazon Elastic Compute Cloud SpotFleet LaunchTemplateConfig

`LaunchTemplateConfig` is a property of the Amazon EC2 SpotFleet SpotFleetRequestConfigData (p. 1265) property that describes a launch template and overrides.

Syntax

JSON

```
{
  "LaunchTemplateSpecification" : LaunchTemplateSpecification (p. 1255),
  "Overrides" : [ LaunchTemplateOverrides (p. 1258), ... ]
}
```

YAML

```
LaunchTemplateSpecification: LaunchTemplateSpecification
Overrides:
  - LaunchTemplateOverrides (p. 1258)
```

Properties

`LaunchTemplateSpecification`

The launch template.

Required: Yes

Type: FleetLaunchTemplateSpecification (p. 1255)

Update requires: No interruption (p. 120)

`Overrides`

Any parameters that you specify override the same parameters in the launch template.

Required: No

Type: List of LaunchTemplateOverrides (p. 1258)

Update requires: No interruption (p. 120)

Amazon Elastic Compute Cloud SpotFleet LaunchTemplateOverrides

`LaunchTemplateOverrides` is a property of the Amazon EC2 SpotFleet SpotFleetRequestConfigData (p. 1265) property that describes overrides for a launch template.

Syntax

JSON

```
{
  "AvailabilityZone" : String,
  "InstanceType" : String,
  "SpotPrice" : String,
  "SubnetId" : String,
  "WeightedCapacity" : Double
}
```

YAML

```
AvailabilityZone: String
InstanceType: String
SpotPrice: String
SubnetId: String
WeightedCapacity: Double
```

Properties

`AvailabilityZone`

The Availability Zone in which to launch the instances.

Required: No

Type: String

Update requires: No interruption (p. 120)

`InstanceType`

The instance type.

For a complete list of valid values, see `InstanceType` in LaunchTemplateOverrides in the *Amazon EC2 API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SpotPrice`

The maximum price per unit hour that you are willing to pay for a Spot Instance.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SubnetId`

The ID of the subnet in which to launch the instances.

Required: No

Type: String

Update requires: No interruption (p. 120)

`WeightedCapacity`

The number of units provided by the specified instance type.

Required: No

Type: Double

Update requires: No interruption (p. 120)

Amazon EC2 SpotFleet LoadBalancersConfig

The `LoadBalancersConfig` property type specifies the Classic Load Balancers and target groups to attach to a Spot Fleet request.

`LoadBalancersConfig` is a property of the Amazon EC2 SpotFleet SpotFleetRequestConfigData (p. 1265) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ClassicLoadBalancersConfig" : ClassicLoadBalancersConfig (p. 1253),
  "TargetGroupsConfig" : TargetGroupsConfig (p. 1269)
}
```

YAML

```
ClassicLoadBalancersConfig:
  ClassicLoadBalancersConfig (p. 1253)
TargetGroupsConfig:
  TargetGroupsConfig (p. 1269)
```

Properties

`ClassicLoadBalancersConfig`

The Classic Load Balancers to attach to the SpotFleet request.

Required: No

Type: Amazon EC2 SpotFleet ClassicLoadBalancersConfig (p. 1253)

Update requires: No interruption (p. 120)

`TargetGroupsConfig`

The target groups to attach to the SpotFleet request.

Required: No

Type: Amazon EC2 SpotFleet TargetGroupsConfig (p. 1269)

Update requires: No interruption (p. 120)

See Also

- LoadBalancersConfig in the *Amazon EC2 API Reference*

Amazon EC2 SpotFleet Monitoring

`Monitoring` is a property of the Amazon Elastic Compute Cloud SpotFleet LaunchSpecifications (p. 1248) property that enables instance monitoring.

Syntax

JSON

```
{
  "Enabled" : Boolean
}
```

YAML

```
Enabled: Boolean
```

Properties

`Enabled`

Indicates whether monitoring is enabled for the instances.

Required: No

Type: Boolean

Amazon Elastic Compute Cloud SpotFleet NetworkInterfaces

`NetworkInterfaces` is a property of the Amazon Elastic Compute Cloud SpotFleet LaunchSpecifications (p. 1248) property that defines the network interface of the instances in a Spot fleet.

Syntax

JSON

```
{
  "AssociatePublicIpAddress" : Boolean,
  "DeleteOnTermination" : Boolean,
  "Description" : String,
```

```
  "DeviceIndex" : Integer,
  "Groups" : [ String, ... ],
  "Ipv6AddressCount" : Integer,
  "Ipv6Addresses" : [ IPv6 Address Type, ... ],
  "NetworkInterfaceId" : String,
  "PrivateIpAddresses" : [ PrivateIpAddresses, ... ],
  "SecondaryPrivateIpAddressCount" : Integer,
  "SubnetId" : String
}
```

YAML

```
AssociatePublicIpAddress: Boolean
DeleteOnTermination: Boolean
Description: String
DeviceIndex: Integer
Groups:
  - String
Ipv6AddressCount: Integer
Ipv6Addresses:
  - IPv6 Address Type
NetworkInterfaceId: String
PrivateIpAddresses:
  - PrivateIpAddresses
SecondaryPrivateIpAddressCount: Integer
SubnetId: String
```

Properties

`AssociatePublicIpAddress`

Indicates whether to assign a public IP address to an instance that you launch in a VPC. You can assign the public IP address can only to a network interface for eth0, and only to a new network interface, not an existing one.

Required: No

Type: Boolean

`DeleteOnTermination`

Indicates whether to delete the network interface when the instance terminates.

Required: No

Type: Boolean

`Description`

The description of this network interface.

Required: No

Type: String

`DeviceIndex`

The network interface's position in the attachment order.

Required: No

Type: Integer

`Groups`

A list of security group IDs to associate with this network interface.

Required: No

Type: List of String values

`Ipv6AddressCount`

The number of IPv6 addresses to associate with the network interface. Amazon Elastic Compute Cloud automatically selects the IPv6 addresses from the subnet range. To specify specific IPv6 addresses, use the `Ipv6Addresses` property and don't specify this property.

Required: No

Type: Integer

`Ipv6Addresses`

One or more specific IPv6 addresses from the IPv6 CIDR block range of your subnet to associate with the network interface. To specify a number of IPv6 addresses, use the `Ipv6AddressCount` property and don't specify this property.

Required: No

Type: List of EC2 NetworkInterface Ipv6Addresses (p. 1213)

`NetworkInterfaceId`

A network interface ID.

Required: No

Type: String

`PrivateIpAddresses`

One or more private IP addresses to assign to the network interface.

Required: No

Type: List of Amazon Elastic Compute Cloud SpotFleet NetworkInterfaces PrivateIpAddresses (p. 1263)

`SecondaryPrivateIpAddressCount`

The number of secondary private IP addresses that Amazon EC2 automatically assigns to the network interface.

Required: No

Type: Integer

`SubnetId`

The ID of the subnet to associate with the network interface.

Required: Conditional. If you don't specify the `NetworkInterfaceId` property, you must specify this property.

Type: String

Amazon Elastic Compute Cloud SpotFleet Placement

`Placement` is a property of the Amazon Elastic Compute Cloud SpotFleet LaunchSpecifications (p. 1248) property that defines the placement group for the Spot instances.

Syntax

JSON

```
{
  "AvailabilityZone" : String,
  "GroupName" : String,
  "Tenancy" : String
}
```

YAML

```
AvailabilityZone: String
GroupName: String
Tenancy: String
```

Properties

For more information, including defaults, valid values, and constraints, see SpotPlacement in the *Amazon EC2 API Reference*

`AvailabilityZone`

The Availability Zone (AZ) of the placement group.

Required: No

Type: String

Update requires: No interruption (p. 120)

`GroupName`

The name of the placement group (for cluster instances).

Required: No

Type: String

Update requires: No interruption (p. 120)

`Tenancy`

The tenancy of the instance (if the instance is running in a VPC). An instance with a tenancy of dedicated runs on single-tenant hardware. The host tenancy is not supported for Spot Instances.

Required: No

Type: String

Update requires: No interruption (p. 120)

Amazon Elastic Compute Cloud SpotFleet NetworkInterfaces PrivateIpAddresses

`PrivateIpAddresses` is a property of the Amazon Elastic Compute Cloud SpotFleet NetworkInterfaces (p. 1260) property that specifies the private IP address that you want to assign to the network interface.

Syntax

JSON

```
{
  "Primary" : Boolean,
  "PrivateIpAddress" : String
}
```

YAML

```
Primary: Boolean
PrivateIpAddress: String
```

Properties

`Primary`

Indicates whether the private IP address is the primary private IP address. You can designate only one IP address as primary.

Required: No

Type: Boolean

`PrivateIpAddress`

The private IP address.

Required: Yes

Type: String

Amazon Elastic Compute Cloud SpotFleet SecurityGroups

`SecurityGroups` is a property of the Amazon Elastic Compute Cloud SpotFleet LaunchSpecifications (p. 1248) property that specifies a security group to associate with the instances.

Syntax

JSON

```
{
  "GroupId" : String
}
```

YAML

```
GroupId: String
```

Properties

`GroupId`

The ID of a security group.

Required: Yes

Type: String

Amazon EC2 SpotFleet SpotFleetRequestConfigData

`SpotFleetRequestConfigData` is a property of the AWS::EC2::SpotFleet (p. 1246) resource that defines the configuration of a Spot fleet request.

Syntax

JSON

```
{
  "AllocationStrategy" : String,
  "ExcessCapacityTerminationPolicy" : String,
  "IamFleetRole" : String,
  "InstanceInterruptionBehavior" : String,
  "LaunchSpecifications" : [ LaunchSpecifications (p. 1248), ... ],
  "LaunchTemplateConfigs" : [ LaunchTemplateConfigs (p. 1257), ... ],
  "LoadBalancersConfig" : LoadBalancersConfig (p. 1259),
  "ReplaceUnhealthyInstances" : Boolean,
  "SpotPrice" : String,
  "TargetCapacity" : Integer,
  "TerminateInstancesWithExpiration" : Boolean,
  "Type" : String,
  "ValidFrom" : String,
  "ValidUntil" : String
}
```

YAML

```
AllocationStrategy: String
ExcessCapacityTerminationPolicy: String
IamFleetRole: String
InstanceInterruptionBehavior: String
LaunchSpecifications:
  - LaunchSpecifications (p. 1248)
LaunchTemplateConfigs:
  - LaunchTemplateConfigs (p. 1257)
LoadBalancersConfig:
  LoadBalancersConfig (p. 1259)
ReplaceUnhealthyInstances: Boolean
SpotPrice: String
TargetCapacity: Integer
TerminateInstancesWithExpiration: Boolean
Type: String
ValidFrom: String
ValidUntil: String
```

Properties

For more information, including property defaults, valid values, and constraints, see SpotFleetRequestConfigData in the *Amazon EC2 API Reference*.

`AllocationStrategy`

Indicates how to allocate the target capacity across the Spot pools that you specified in the Spot fleet request.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ExcessCapacityTerminationPolicy`

Indicates whether running Spot instances are terminated if you decrease the target capacity of the Spot fleet request below the current size of the Spot fleet.

Required: No

Type: String

Update requires: No interruption (p. 120)

`IamFleetRole`

The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role that grants the Spot fleet the ability to bid on, launch, and terminate instances on your behalf. For more information, see Spot Fleet Prerequisites in the *Amazon EC2 User Guide for Linux Instances*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`InstanceInterruptionBehavior`

The behavior when a Spot Instance is interrupted.

Required: No

Type: String

Update requires: Replacement (p. 121)

`LaunchSpecifications`

The launch specifications for the Spot fleet request.

Required: Conditional. You must specify either `LaunchSpecifications` or `LaunchTemplateConfigs`.

Type: List of Amazon Elastic Compute Cloud SpotFleet LaunchSpecifications (p. 1248)

Update requires: Replacement (p. 121)

`LaunchTemplateConfigs`

Describes a launch template and overrides.

Required: Conditional. You must specify either `LaunchSpecifications` or `LaunchTemplateConfigs`.

Type: List of LaunchTemplateConfig (p. 1257)

Update requires: Replacement (p. 121)

`LoadBalancersConfig`

One or more Classic Load Balancers and target groups to attach to the Spot Fleet request. Spot Fleet registers the running Spot Instances with the specified Classic Load Balancers and target groups.

Required: No

Type: LoadBalancersConfig (p. 1259)

Update requires: Replacement (p. 121)

`ReplaceUnhealthyInstances`

Indicates whether the Spot fleet should replace unhealthy instances.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`SpotPrice`

The bid price per unit hour. For more information, see How Spot Fleet Works in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`TargetCapacity`

The number of units to request for the spot fleet. You can choose to set the target capacity as the number of instances or as a performance characteristic that is important to your application workload, such as vCPUs, memory, or I/O. For more information, see How Spot Fleet Works in the *Amazon EC2 User Guide for Linux Instances*.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

`TerminateInstancesWithExpiration`

Indicates whether running Spot instances are terminated when the Spot fleet request expires.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`Type`

The type of request, which indicates whether the fleet will only request the target capacity or also attempt to maintain it.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ValidFrom`

The start date and time of the request, in UTC format (*YYYY*-*MM*-*DD*T*HH*:*MM*:*SS*Z). By default, Amazon Elastic Compute Cloud (Amazon EC2) starts fulfilling the request immediately.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ValidUntil`

The end date and time of the request, in UTC format (*YYYY*-*MM*-*DD*T*HH*:*MM*:*SS*Z). After the end date and time, Amazon EC2 doesn't request new Spot instances or enable them to fulfill the request.

Required: No

Type: String

Update requires: Replacement (p. 121)

Amazon Elastic Compute Cloud SpotFleet SpotFleetTagSpecification

`SpotFleetTagSpecification` is a property of the Amazon Elastic Compute Cloud SpotFleet LaunchSpecifications (p. 1248) property that specifies the tags for a Spot fleet resource.

Syntax

JSON

```
{
  "ResourceType" : String,
  "Tags" : [ Resource Tag, ... ]
}
```

YAML

```
ResourceType: String
Tags:
    - Resource Tag
```

Properties

`ResourceType`

The type of resource.

For valid resource types, see SpotFleetTagSpecification operation in the *Amazon EC2 API Reference*

Required: No

Type: String

Update requires: No interruption (p. 120)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this spot fleet. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Amazon EC2 SpotFleet TargetGroup

The `TargetGroup` property type describes a load balancer target group.

`TargetGroup` is a property of the Amazon EC2 SpotFleet TargetGroupsConfig (p. 1269) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Arn" : String
}
```

YAML

```
Arn: String
```

Properties

`Arn`

The Amazon Resource Name (ARN) of the target group.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

See Also

- TargetGroup in the *Amazon EC2 API Reference*

Amazon EC2 SpotFleet TargetGroupsConfig

The `TargetGroupsConfig` property type describes the target groups to attach to a Spot Fleet. Spot Fleet registers the running Spot Instances with these target groups.

`TargetGroupsConfig` is a property of the Amazon EC2 SpotFleet LoadBalancersConfig (p. 1259) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "TargetGroups" : [ TargetGroup (p. 1268), ... ]
}
```

YAML

```
TargetGroups:
  - TargetGroup (p. 1268)
```

Properties

`TargetGroups`

One or more target groups. Duplicates not allowed. For property constraints, see TargetGroupsConfig in the *Amazon EC2 API Reference*

Required: Yes

Type: List of Amazon EC2 SpotFleet TargetGroup (p. 1268)

Update requires: No interruption (p. 120)

See Also

- TargetGroupsConfig in the *Amazon EC2 API Reference*

AWS::EC2::Subnet

Creates a subnet in an existing VPC.

Topics

- Syntax (p. 1270)
- Properties (p. 1271)
- Return Values (p. 1272)
- Example (p. 1273)
- More Info (p. 1273)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::Subnet",
  "Properties" : {
    "AssignIpv6AddressOnCreation" : Boolean,
    "AvailabilityZone (p. 1271)" : String,
    "CidrBlock (p. 1271)" : String,
    "Ipv6CidrBlock" : String,
    "MapPublicIpOnLaunch" : Boolean,
    "Tags (p. 1272)" : [ Resource Tag, ... ],
    "VpcId (p. 1272)" : String
  }
}
```

YAML

```
Type: AWS::EC2::Subnet
Properties:
  AssignIpv6AddressOnCreation: Boolean
  AvailabilityZone (p. 1271): String
  CidrBlock (p. 1271): String
  Ipv6CidrBlock: String
  MapPublicIpOnLaunch: Boolean
  Tags (p. 1272):
```

```
    - Resource Tag
  VpcId (p. 1272): String
```

Properties

`AssignIpv6AddressOnCreation`

Indicates whether a network interface created in this subnet receives an IPv6 address. The default value is `false`.

Required: Conditional. If you specify a `true` or `false` value for `AssignIpv6AddressOnCreation`, `Ipv6CidrBlock` must also be specified.

Type: Boolean

Update requires: No interruption (p. 120)

> **Note**
> If `AssignIpv6AddressOnCreation` is specified, `MapPublicIpOnLaunch` cannot be specified.

`AvailabilityZone`

The availability zone in which you want the subnet. Default: AWS selects a zone for you (recommended).

Required: No

Type: String

Update requires: Replacement (p. 121)

> **Note**
> If you update this property, you must also update the `CidrBlock` property.

`CidrBlock`

The CIDR block that you want the subnet to cover (for example, `"10.0.0.0/24"`).

Required: Yes

Type: String

Update requires: Replacement (p. 121)

> **Note**
> If you update this property, you must also update the `AvailabilityZone` property.

`Ipv6CidrBlock`

The IPv6 network range for the subnet, in CIDR notation. The subnet size must use a `/64` prefix length.

Required: Conditional. If you specify a `true` or `false` value for `AssignIpv6AddressOnCreation`, `Ipv6CidrBlock` must be specified.

Type: String

Update requires: No interruption (p. 120)

`MapPublicIpOnLaunch`

Indicates whether instances that are launched in this subnet receive a public IP address. By default, the value is `false`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

Note
If `MapPublicIpOnLaunch` is specified. `AssignIpv6AddressOnCreation` cannot be specified.

`Tags`

An arbitrary set of tags (key–value pairs) for this subnet.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`VpcId`

A Ref structure that contains the ID of the VPC on which you want to create the subnet. The VPC ID is provided as the value of the "Ref" property, as: `{ "Ref": "VPCID" }`.

Required: Yes

Type: Ref ID

Update requires: Replacement (p. 121)

Note
If you update this property, you must also update the `CidrBlock` property.

Return Values

You can pass the logical ID of the resource to an intrinsic function to get a value back from the resource. The value that is returned depends on the function that you used.

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource ID, such as `subnet-e19f0178`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`AvailabilityZone`

Returns the availability zone (for example, "`us-east-1a`") of this subnet.

Example:

```
{ "Fn::GetAtt" : [ "mySubnet", "AvailabilityZone" ] }
```

`Ipv6CidrBlocks`

A list of IPv6 CIDR blocks that are associated with the subnet, such as `[ 2001:db8:1234:1a00::/64 ]`.

`NetworkAclAssociationId`

The ID of the network ACL that is associated with the subnet's VPC, such as `acl-5fb85d36`.

`VpcId`

The ID of the subnet's VPC, such as `vpc-11ad4878`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example snippet uses the VPC ID from a VPC named *myVPC* that was declared elsewhere in the same template.

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "mySubnet" : {
         "Type" : "AWS::EC2::Subnet",
         "Properties" : {
            "VpcId" : { "Ref" : "myVPC" },
            "CidrBlock" : "10.0.0.0/24",
            "AvailabilityZone" : "us-east-1a",
            "Tags" : [ { "Key" : "foo", "Value" : "bar" } ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  mySubnet:
    Type: AWS::EC2::Subnet
    Properties:
      VpcId:
        Ref: myVPC
      CidrBlock: 10.0.0.0/24
      AvailabilityZone: "us-east-1a"
      Tags:
      - Key: foo
        Value: bar
```

More Info

- CreateSubnet in the *Amazon EC2 API Reference*
- Using Tags in the *Amazon Elastic Compute Cloud User Guide*

AWS::EC2::SubnetCidrBlock

The `AWS::EC2::SubnetCidrBlock` resource associates a single IPv6 CIDR block with an Amazon VPC subnet.

Topics

- Syntax (p. 1274)
- Properties (p. 1274)
- Example (p. 1274)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::SubnetCidrBlock",
   "Properties" : {
      "Ipv6CidrBlock" : String,
      "SubnetId" : String
   }
}
```

YAML

```
Type: AWS::EC2::SubnetCidrBlock
Properties:
  Ipv6CidrBlock: String
  SubnetId: String
```

Properties

`Ipv6CidrBlock`

The IPv6 CIDR block for the subnet. The CIDR block must have a prefix length of /64.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SubnetId`

The ID of the subnet to associate the IPv6 CIDR block with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Example

The following example associates an IPv6 CIDR block (with a prefix length of /64) with the `Ipv6TestSubnet` subnet.

JSON

```
{
  "Ipv6TestSubnetCidrBlock": {
```

```
    "Type": "AWS::EC2::SubnetCidrBlock",
    "Properties": {
      "Ipv6CidrBlock": { "Ref" : "Ipv6SubnetCidrBlock" },
      "SubnetId": { "Ref" : "Ipv6TestSubnet" }
    }
  }
}
```

YAML

```
Ipv6TestSubnetCidrBlock:
  Type: AWS::EC2::SubnetCidrBlock
  Properties:
    Ipv6CidrBlock: !Ref Ipv6SubnetCidrBlock
    SubnetId: !Ref Ipv6TestSubnet
```

AWS::EC2::SubnetNetworkAclAssociation

Associates a subnet with a network ACL. For more information, see ReplaceNetworkAclAssociation in the *Amazon EC2 API Reference*.

When `AWS::EC2::SubnetNetworkAclAssociation` resources are created during create or update operations, AWS CloudFormation adopts existing resources that share the same key properties (the properties that contribute to uniquely identify the resource). However, if the operation fails and rolls back, AWS CloudFormation deletes the previously out-of-band resources. You can protect against this behavior by using `Retain` deletion policies. For more information, see DeletionPolicy Attribute (p. 2273).

> **Note**
> The EC2 API Reference refers to the `SubnetId` parameter as the `AssociationId`.

Topics

- Syntax (p. 1275)
- Properties (p. 1276)
- Return Values (p. 1276)
- Template Examples (p. 1276)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::SubnetNetworkAclAssociation",
  "Properties" : {
    "SubnetId (p. 1276)" : String,
    "NetworkAclId (p. 1276)" : String
  }
}
```

YAML

```
Type: AWS::EC2::SubnetNetworkAclAssociation
Properties:
```

```
  SubnetId (p. 1276): String
  NetworkAclId (p. 1276): String
```

Properties

`SubnetId`

The ID representing the current association between the original network ACL and the subnet.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`NetworkAclId`

The ID of the new ACL to associate with the subnet.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`AssociationId`

Returns the value of this object's SubnetId (p. 1276) property.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Template Examples

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "mySubnetNetworkAclAssociation" : {
         "Type" : "AWS::EC2::SubnetNetworkAclAssociation",
         "Properties" : {
            "SubnetId" : { "Ref" : "mySubnet" },
            "NetworkAclId" : { "Ref" : "myNetworkAcl" }
         }
```

```
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  mySubnetNetworkAclAssociation:
    Type: AWS::EC2::SubnetNetworkAclAssociation
    Properties:
      SubnetId:
        Ref: mySubnet
      NetworkAclId:
        Ref: myNetworkAcl
```

AWS::EC2::SubnetRouteTableAssociation

Associates a subnet with a route table.

When `AWS::EC2::SubnetRouteTableAssociation` resources are created during create or update operations, AWS CloudFormation adopts existing resources that share the same key properties (the properties that contribute to uniquely identify the resource). However, if the operation fails and rolls back, AWS CloudFormation deletes the previously out-of-band resources. You can protect against this behavior by using `Retain` deletion policies. For more information, see DeletionPolicy Attribute (p. 2273).

Topics

- Syntax (p. 1277)
- Properties (p. 1278)
- Return Value (p. 1278)
- Example (p. 1278)
- See Also (p. 1279)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::SubnetRouteTableAssociation",
  "Properties" : {
    "RouteTableId (p. 1278)" : String,
    "SubnetId (p. 1278)" : String
  }
}
```

YAML

```
Type: AWS::EC2::SubnetRouteTableAssociation
Properties:
  RouteTableId (p. 1278): String
  SubnetId (p. 1278): String
```

Properties

`RouteTableId`

The ID of the route table. This is commonly written as a reference to a route table declared elsewhere in the template. For example:

```
"RouteTableId" : { "Ref" : "myRouteTable" }
```

Required: Yes

Type: String

Update requires: No interruption (p. 120). However, the physical ID changes when the route table ID is changed.

`SubnetId`

The ID of the subnet. This is commonly written as a reference to a subnet declared elsewhere in the template. For example:

```
"SubnetId" : { "Ref" : "mySubnet" }
```

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Value

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyRTA" }
```

For the subnet route table association with the logical ID "MyRTA", Ref will return the AWS resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "mySubnetRouteTableAssociation" : {
         "Type" : "AWS::EC2::SubnetRouteTableAssociation",
         "Properties" : {
            "SubnetId" : { "Ref" : "mySubnet" },
            "RouteTableId" : { "Ref" : "myRouteTable" }
         }
      }
   }
```

```
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  mySubnetRouteTableAssociation:
    Type: AWS::EC2::SubnetRouteTableAssociation
    Properties:
      SubnetId:
        Ref: mySubnet
      RouteTableId:
        Ref: myRouteTable
```

See Also

- AssociateRouteTable in the *Amazon EC2 API Reference*

AWS::EC2::Volume

The `AWS::EC2::Volume` type creates a new Amazon Elastic Block Store (Amazon EBS) volume.

> **Important**
> When you use AWS CloudFormation to update an Amazon EBS volume that modifies `Iops`, `Size`, or `VolumeType`, there is a cooldown period before another operation can occur. This can cause your stack to report being in `UPDATE_IN_PROGRESS` or `UPDATE_ROLLBACK_IN_PROGRESS` for long periods of time.

Some common scenarios when you might encounter a cooldown period for Amazon EBS include:

- You successfully update an Amazon EBS volume and the update succeeds. When you attempt another update within the cooldown window, that update will be subject to a cooldown period.
- You successfully update an Amazon EBS volume and the update succeeds but another change in your `update-stack` call fails. The rollback will be subject to a cooldown period.

For more information on the cooldown period, see Considerations for Modifying EBS Volumes in the *Amazon EBS Developer Guide*.

To control how AWS CloudFormation handles the volume when the stack is deleted, set a deletion policy for your volume. You can choose to *retain* the volume, to *delete* the volume, or to *create a snapshot* of the volume. For more information, see DeletionPolicy Attribute (p. 2273).

> **Note**
> If you set a deletion policy that creates a snapshot, all tags on the volume are included in the snapshot.

> **Important**
> Amazon EBS does not support sizing down an Amazon EBS volume. AWS CloudFormation will not attempt to modify an Amazon EBS volume to a smaller size on rollback.

> **Note**
> Amazon EBS does not support modifying a Magnetic volume. For more information, see Considerations for Modifying EBS Volumes.

Topics

- Syntax (p. 1280)
- Properties (p. 1280)

- Return Values (p. 1282)
- Examples (p. 1282)
- More Info (p. 1283)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type":"AWS::EC2::Volume",
   "Properties" : {
      "AutoEnableIO" : Boolean,
      "AvailabilityZone (p. 1281)" : String,
      "Encrypted" : Boolean,
      "Iops (p. 1281)" : Number,
      "KmsKeyId" : String,
      "Size (p. 1281)" : Integer,
      "SnapshotId (p. 1282)" : String,
      "Tags (p. 1282)" : [ Resource Tag, ... ],
      "VolumeType (p. 1282)" : String
   }
}
```

YAML

```
Type: AWS::EC2::Volume
Properties:
  AutoEnableIO: Boolean
  AvailabilityZone (p. 1281): String
  Encrypted: Boolean
  Iops (p. 1281): Number
  KmsKeyId: String
  Size (p. 1281): Integer
  SnapshotId (p. 1282): String
  Tags (p. 1282):
    - Resource Tag
  VolumeType (p. 1282): String
```

Properties

`AutoEnableIO`

Indicates whether the volume is auto-enabled for I/O operations. By default, Amazon EBS disables I/O to the volume from attached EC2 instances when it determines that a volume's data is potentially inconsistent. If the consistency of the volume is not a concern, and you prefer that the volume be made available immediately if it's impaired, you can configure the volume to automatically enable I/O. For more information, see Working with the AutoEnableIO Volume Attribute in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`AvailabilityZone`

The Availability Zone in which to create the new volume.

Required: Yes

Type: String

Update requires: Updates are not supported.

`Encrypted`

Indicates whether the volume is encrypted. You can attach encrypted Amazon EBS volumes only to instance types that support Amazon EBS encryption. Volumes that are created from encrypted snapshots are automatically encrypted. You can't create an encrypted volume from an unencrypted snapshot, or vice versa. If your AMI uses encrypted volumes, you can launch the AMI only on supported instance types. For more information, see Amazon EBS encryption in the *Amazon EC2 User Guide for Linux Instances*.

Required: Conditional. If you specify the `KmsKeyId` property, you must enable encryption.

Type: Boolean

Update requires: Updates are not supported.

`Iops`

The number of I/O operations per second (IOPS) that the volume supports. For more information about the valid sizes for each volume type, see the `Iops` parameter for the `CreateVolume` action in the *Amazon EC2 API Reference*.

Required: Conditional. *Required* when the volume type is `io1`; not used with other volume types.

Type: Number

Update requires: No interruption (p. 120)

`KmsKeyId`

The Amazon Resource Name (ARN) of the AWS Key Management Service master key that is used to create the encrypted volume, such as `arn:aws:kms:us-east-2:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef`. If you create an encrypted volume and don't specify this property, AWS CloudFormation uses the default master key.

Required: No

Type: String

Update requires: Updates are not supported.

`Size`

The size of the volume, in gibibytes (GiBs). For more information about the valid sizes for each volume type, see the `Size` parameter for the `CreateVolume` action in the *Amazon EC2 API Reference*.

If you specify the `SnapshotId` property, specify a size that is equal to or greater than the size of the snapshot. If you don't specify a size, EC2 uses the size of the snapshot as the volume size.

Required: Conditional. If you don't specify a value for the `SnapshotId` property, you must specify this property.

Type: Integer

Update requires: No interruption (p. 120)

`SnapshotId`

The snapshot from which to create the new volume.

Required: No

Type: String

Update requires: Updates are not supported.

`Tags`

An arbitrary set of tags (key–value pairs) for this volume.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`VolumeType`

The volume type. If you set the type to `io1`, you must also set the `Iops` property. For valid values, see the `VolumeType` parameter for the CreateVolume action in the *Amazon EC2 API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When you specify an `AWS::EC2::Volume` type as an argument to the `Ref` function, AWS CloudFormation returns the volume's physical ID. For example: `vol-5cb85026`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Example Encrypted Amazon EBS Volume with DeletionPolicy to Make a Snapshot on Delete

```
"NewVolume" : {
   "Type" : "AWS::EC2::Volume",
   "Properties" : {
      "Size" : "100",
      "Encrypted" : "true",
      "AvailabilityZone" : { "Fn::GetAtt" : [ "Ec2Instance", "AvailabilityZone" ] },
      "Tags" : [ {
         "Key" : "MyTag",
         "Value" : "TagValue"
      } ]
   },
   "DeletionPolicy" : "Snapshot"
}
```

Example Amazon EBS Volume with 100 Provisioned IOPS

```
"NewVolume" : {
   "Type" : "AWS::EC2::Volume",
   "Properties" : {
     "Size" : "100",
     "VolumeType" : "io1",
     "Iops" : "100",
     "AvailabilityZone" : { "Fn::GetAtt" : [ "EC2Instance", "AvailabilityZone" ] }
   }
}
```

More Info

- CreateVolume in the *Amazon Elastic Compute Cloud API Reference*
- DeletionPolicy Attribute (p. 2273)

AWS::EC2::VolumeAttachment

Attaches an Amazon EBS volume to a running instance and exposes it to the instance with the specified device name.

> **Important**
> Before this resource can be deleted (and therefore the volume detached), you must first unmount the volume in the instance. Failure to do so results in the volume being stuck in the busy state while it is trying to detach, which could possibly damage the file system or the data it contains.
> If an Amazon EBS volume is the root device of an instance, it cannot be detached while the instance is in the "running" state. To detach the root volume, stop the instance first.
> If the root volume is detached from an instance with an AWS Marketplace product code, then the AWS Marketplace product codes from that volume are no longer associated with the instance.

Topics

- Syntax (p. 1283)
- Properties (p. 1284)
- Example (p. 1284)
- See Also (p. 1285)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type":"AWS::EC2::VolumeAttachment",
   "Properties" : {
      "Device (p. 1284)" : String,
      "InstanceId (p. 1284)" : String,
      "VolumeId (p. 1284)" : String
   }
}
```

YAML

```
Type: AWS::EC2::VolumeAttachment
Properties:
  Device (p. 1284): String
  InstanceId (p. 1284): String
  VolumeId (p. 1284): String
```

Properties

`Device`

How the device is exposed to the instance (e.g., /dev/sdh, or xvdh).

Required: Yes

Type: String

Update requires: Updates are not supported.

`InstanceId`

The ID of the instance to which the volume attaches. This value can be a reference to an AWS::EC2::Instance (p. 1155) resource, or it can be the physical ID of an existing EC2 instance.

Required: Yes

Type: String

Update requires: Updates are not supported.

`VolumeId`

The ID of the Amazon EBS volume. The volume and instance must be within the same Availability Zone. This value can be a reference to an AWS::EC2::Volume (p. 1279) resource, or it can be the volume ID of an existing Amazon EBS volume.

Required: Yes

Type: String

Update requires: Updates are not supported.

Example

This example attaches an EC2 EBS volume to the EC2 instance with the logical name "Ec2Instance".

```
"NewVolume" : {
   "Type" : "AWS::EC2::Volume",
   "Properties" : {
      "Size" : "100",
      "AvailabilityZone" : { "Fn::GetAtt" : [ "Ec2Instance", "AvailabilityZone" ] },
      "Tags" : [ {
         "Key" : "MyTag",
         "Value" : "TagValue"
      } ]
   }
},
```

```
"MountPoint" : {
   "Type" : "AWS::EC2::VolumeAttachment",
   "Properties" : {
      "InstanceId" : { "Ref" : "Ec2Instance" },
      "VolumeId"  : { "Ref" : "NewVolume" },
      "Device" : "/dev/sdh"
   }
}
```

AWS::EC2::VPC

Creates a Virtual Private Cloud (VPC) with the CIDR block that you specify. To name a VPC resource, use the `Tags` property and specify a value for the `Name` key.

Topics

- Syntax (p. 1285)
- Properties (p. 1286)
- Return Values (p. 1287)
- Example (p. 1287)
- More Info (p. 1288)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::VPC",
   "Properties" : {
      "CidrBlock (p. 1286)" : String,
      "EnableDnsSupport (p. 1286)" : Boolean,
      "EnableDnsHostnames (p. 1286)" : Boolean,
      "InstanceTenancy (p. 1286)" : String,
      "Tags (p. 1286)" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::EC2::VPC
Properties:
  CidrBlock (p. 1286): String
  EnableDnsSupport (p. 1286): Boolean
  EnableDnsHostnames (p. 1286): Boolean
  InstanceTenancy (p. 1286): String
  Tags (p. 1286):
```

```
    - Resource Tag
```

Properties

`CidrBlock`

The CIDR block you want the VPC to cover. For example: `"10.0.0.0/16"`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`EnableDnsSupport`

Specifies whether DNS resolution is supported for the VPC. If this attribute is `true`, the Amazon DNS server resolves DNS hostnames for your instances to their corresponding IP addresses; otherwise, it does not. By default the value is set to `true`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`EnableDnsHostnames`

Specifies whether the instances launched in the VPC get DNS hostnames. If this attribute is `true`, instances in the VPC get DNS hostnames; otherwise, they do not. You can only set `EnableDnsHostnames` to `true` if you also set the `EnableDnsSupport` attribute to `true`. By default, the value is set to `false`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`InstanceTenancy`

The allowed tenancy of instances launched into the VPC.

- `"default"`: Instances can be launched with any tenancy.
- `"dedicated"`: Any instance launched into the VPC automatically has dedicated tenancy, unless you launch it with the default tenancy.

Update: Conditional. Updating `InstanceTenancy` requires no replacement only if you are updating its value from `"dedicated"` to `"default"`. Updating `InstanceTenancy` from `"default"` to `"dedicated"` requires replacement.

Required: No

Type: String

Valid values: `"default"` or `"dedicated"`

Update requires: No interruption (p. 120)

`Tags`

An arbitrary set of tags (key–value pairs) for this VPC. To name a VPC resource, specify a value for the `Name` key.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource ID, such as `vpc-18ac277d`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`CidrBlock`

The set of IP addresses for the VPC. For example, `10.0.0.0/16`.

`CidrBlockAssociations`

A list of IPv4 CIDR block association IDs for the VPC. For example, `[ vpc-cidr-assoc-0280ab6b ]`.

`DefaultNetworkAcl`

The default network ACL ID that is associated with the VPC. For example, `acl-814dafe3`.

`DefaultSecurityGroup`

The default security group ID that is associated with the VPC. For example, `sg-b178e0d3`.

`Ipv6CidrBlocks`

A list of IPv6 CIDR blocks that are associated with the VPC, such as `[ 2001:db8:1234:1a00::/56 ]`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myVPC" : {
         "Type" : "AWS::EC2::VPC",
         "Properties" : {
            "CidrBlock" : "10.0.0.0/16",
         "EnableDnsSupport" : "false",
         "EnableDnsHostnames" : "false",
            "InstanceTenancy" : "dedicated",
            "Tags" : [ {"Key" : "foo", "Value" : "bar"} ]
         }
```

```
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  myVPC:
    Type: AWS::EC2::VPC
    Properties:
      CidrBlock: 10.0.0.0/16
      EnableDnsSupport: 'false'
      EnableDnsHostnames: 'false'
      InstanceTenancy: dedicated
      Tags:
      - Key: foo
        Value: bar
```

More Info

- CreateVpc in the *Amazon EC2 API Reference*.

AWS::EC2::VPCCidrBlock

The `AWS::EC2::VPCCidrBlock` resource associates a single Amazon-provided IPv6 CIDR block or a single user-specified IPv4 CIDR block with a Virtual Private Cloud (VPC).

Topics

- Syntax (p. 1288)
- Properties (p. 1289)
- Examples (p. 1289)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::VPCCidrBlock",
   "Properties" : {
      "AmazonProvidedIpv6CidrBlock" : Boolean,
      "CidrBlock" : String,
      "VpcId" : String
   }
}
```

YAML

```
Type: AWS::EC2::VPCCidrBlock
Properties:
  AmazonProvidedIpv6CidrBlock: Boolean
  CidrBlock: String
  VpcId: String
```

Properties

`AmazonProvidedIpv6CidrBlock`

Whether to request an Amazon-provided IPv6 CIDR block with a /56 prefix length for the VPC. You can't specify the range of IPv6 addresses or the size of the CIDR block.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`CidrBlock`

An IPv4 CIDR block to associate with the VPC.

Required: No

Type: String

Update requires: Replacement (p. 121)

`VpcId`

The ID of the VPC to associate the Amazon-provided IPv6 CIDR block with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Examples

Associate an Amazon-provided IPv6 CIDR block

The following snippet associates an Amazon-provided IPv6 CIDR block (with a prefix length of /56) with the `TestVPCIpv6` VPC.

JSON

```
{
  "Ipv6VPCCidrBlock": {
    "Type": "AWS::EC2::VPCCidrBlock",
    "Properties": {
      "AmazonProvidedIpv6CidrBlock": true,
      "VpcId": { "Ref" : "TestVPCIpv6" }
    }
  }
}
```

YAML

```
Ipv6VPCCidrBlock:
  Type: AWS::EC2::VPCCidrBlock
  Properties:
    AmazonProvidedIpv6CidrBlock: true
    VpcId: !Ref TestVPCIpv6
```

Associate an IPv4 CIDR block and Amazon-provided IPv6 CIDR block

The following example associates an IPv4 CIDR block and an Amazon-provided IPv6 CIDR block with a VPC. It also outputs the list of IPv4 CIDR block association IDs and IPv6 CIDR blocks that are associated with the VPC.

JSON

```
{
    "Resources": {
        "VPC": {
            "Type": "AWS::EC2::VPC",
            "Properties": {
                "CidrBlock": "10.0.0.0/24"
            }
        },
        "VpcCidrBlock": {
            "Type": "AWS::EC2::VPCCidrBlock",
            "Properties": {
                "VpcId": {
                    "Ref": "VPC"
                },
                "CidrBlock": "192.0.0.0/24"
            }
        },
        "VpcCidrBlockIpv6": {
            "Type": "AWS::EC2::VPCCidrBlock",
            "Properties": {
                "VpcId": {
                    "Ref": "VPC"
                },
                "AmazonProvidedIpv6CidrBlock": true
            }
        }
    },
    "Outputs": {
        "VpcId": {
            "Value": {
                "Ref": "VPC"
            }
        },
        "PrimaryCidrBlock": {
            "Value": {
                "Fn::GetAtt": [
                    "VPC",
                    "CidrBlock"
                ]
            }
        },
        "Ipv6CidrBlock": {
            "Value": {
                "Fn::Select": [
                    0,
                    {
                        "Fn::GetAtt": [
                            "VPC",
                            "Ipv6CidrBlocks"
                        ]
                    }
                ]
            }
        },
        "CidrBlockAssociation": {
            "Value": {
                "Fn::Select": [
```

```
                    0,
                    {
                        "Fn::GetAtt": [
                            "VPC",
                            "CidrBlockAssociations"
                        ]
                    }
                ]
            }
        }
    }
}
```

YAML

```
Resources:
  VPC:
    Type: AWS::EC2::VPC
    Properties:
      CidrBlock: 10.0.0.0/24
  VpcCidrBlock:
    Type: AWS::EC2::VPCCidrBlock
    Properties:
      VpcId: !Ref VPC
      CidrBlock: 192.0.0.0/24
  VpcCidrBlockIpv6:
    Type: AWS::EC2::VPCCidrBlock
    Properties:
      VpcId: !Ref VPC
      AmazonProvidedIpv6CidrBlock: true

Outputs:
  VpcId:
    Value: !Ref VPC
  PrimaryCidrBlock:
    Value: !GetAtt VPC.CidrBlock
  Ipv6CidrBlock:

  CidrBlockAssociation:
    Value: !Select [ 0, !GetAtt VPC.CidrBlockAssociations ]
```

AWS::EC2::VPCDHCPOptionsAssociation

Associates a set of DHCP options (that you've previously created) with the specified VPC.

Topics

- Syntax (p. 1291)
- Properties (p. 1292)
- Return Values (p. 1292)
- Example (p. 1292)
- See Also (p. 1293)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::VPCDHCPOptionsAssociation",
   "Properties" : {
      "DhcpOptionsId (p. 1292)" : String,
      "VpcId (p. 1292)" : String
   }
}
```

YAML

```
Type: AWS::EC2::VPCDHCPOptionsAssociation
Properties:
  DhcpOptionsId (p. 1292): String
  VpcId (p. 1292): String
```

Properties

`DhcpOptionsId`

The ID of the DHCP options you want to associate with the VPC. Specify `default` if you want the VPC to use no DHCP options.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`VpcId`

The ID of the VPC to associate with this DHCP options set.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following snippet uses the `Ref` intrinsic function to associate the `myDHCPOptions` DHCP options with the `myVPC` VPC. The VPC and DHCP options can be declared in the same template or added as input parameters. For more information about the VPC or the DHCP options resources, see AWS::EC2::VPC (p. 1285) or AWS::EC2::DHCPOptions (p. 1139).

JSON

```
"myVPCDHCPOptionsAssociation" : {
  "Type" : "AWS::EC2::VPCDHCPOptionsAssociation",
```

```
  "Properties" : {
    "VpcId" : {"Ref" : "myVPC"},
    "DhcpOptionsId" : {"Ref" : "myDHCPOptions"}
  }
}
```

YAML

```
myVPCDHCPOptionsAssociation:
  Type: AWS::EC2::VPCDHCPOptionsAssociation
  Properties:
    VpcId:
      Ref: myVPC
    DhcpOptionsId:
      Ref: myDHCPOptions
```

See Also

- AssociateDhcpOptions in the *Amazon EC2 API Reference*.

AWS::EC2::VPCEndpoint

Creates a VPC endpoint that you can use to establish a private connection between your VPC and another AWS service without requiring access over the Internet, a VPN connection, or AWS Direct Connect. For more information, see CreateVpcEndpoint.

Topics

- Syntax (p. 1293)
- Properties (p. 1294)
- Return Value (p. 1295)
- Example (p. 1296)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::VPCEndpoint",
  "Properties" : {
    "VpcId" : String,
    "RouteTableIds" : [ String, ... ],
    "ServiceName" : String,
    "PolicyDocument" : String,
    "VpcEndpointType" : String,
    "PrivateDnsEnabled" : Boolean,
    "SubnetIds" : [ String, ... ],
    "SecurityGroupIds" : [ String, ... ]
  }
}
```

YAML

```
Type: AWS::EC2::VPCEndpoint
Properties:
  VpcId: String
  RouteTableIds:
    - String
  ServiceName: String
  PolicyDocument: String
  VpcEndpointType: String
  PrivateDnsEnabled: Boolean
  SubnetIds:
    - String
  SecurityGroupIds:
    - String
```

Properties

`PrivateDnsEnabled`

[Interface endpoint] Indicates whether to associate a private hosted zone with the specified VPC.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`PolicyDocument`

[Gateway endpoint] A policy to attach to the endpoint that controls access to the service. The policy must be valid JSON. The default policy allows full access to the AWS service. For more information, see Controlling Access to Services in the *Amazon VPC User Guide*.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`RouteTableIds`

One or more route table IDs that are used by the VPC to reach the endpoint.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SecurityGroupIds`

[Interface endpoint] The ID of one or more security groups to associate with the endpoint network interface.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`ServiceName`

The name of the service. To get a list of available services, use DescribeVpcEndpointServices or get the name from the service provider.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SubnetIds`

[Interface endpoint] The ID of one or more subnets in which to create an endpoint network interface.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`VpcEndpointType`

The type of endpoint. Valid values are `Interface` and `Gateway`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`VpcId`

The ID of the VPC in which the endpoint will be used.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Value

Ref

When you pass the logical ID of an `AWS::EC2::VPCEndpoint` resource to the intrinsic `Ref` function, the function returns the endpoint ID, such as `vpce-a123d0d1`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`CreationTimestamp`

Returns: The date and time the VPC endpoint was created. For example: `Fri Sep 28 23:34:36 UTC 2018`

`DnsEntries`

Returns: (Interface endpoint) A list of the DNS entries for the endpoint. Each entry is a combination of the hosted zone ID and the DNS name. In the first entry in the list below, for example, `Z1C12344VYDITB0` is the hosted zone ID and `ec2.us-east-1.amazonaws.com` is the DNS name. Note that if you update the `PrivateDnsEnabled` or `SubnetIds` properties, the order of DNS entries in this list may change as well.

For example:

```
[ "Z1C12344VYDITB0:ec2.us-east-1.amazonaws.com",
"Z1HUB23UULQXV:vpce-01abc23456de78f9g-12abccd3.ec2.us-
east-1.vpce.amazonaws.com"]
```

`NetworkInterfaceIds`

Returns: (Interface endpoint) A list of one or more network interfaces for the endpoint. For example:

```
[ "eni-12345ab6789c10d1e", "eni-012345678ab9c10d1" ]
```

> **Note**
> If you update the `PrivateDnsEnabled` or `SubnetIds` properties, the order of the items in this list might change.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example creates a VPC endpoint that allows only the `s3:GetObject` action on the `examplebucket` bucket. Traffic to S3 within subnets that are associated with the `routetableA` and `routetableB` route tables is automatically routed through the VPC endpoint.

JSON

```
"S3Endpoint" : {
  "Type" : "AWS::EC2::VPCEndpoint",
  "Properties" : {
    "PolicyDocument" : {
      "Version":"2012-10-17",
      "Statement":[{
        "Effect":"Allow",
        "Principal": "*",
        "Action":["s3:GetObject"],
        "Resource":["arn:aws:s3:::examplebucket/*"]
      }]
    },
    "RouteTableIds" : [ {"Ref" : "routetableA"}, {"Ref" : "routetableB"} ],
    "ServiceName" : { "Fn::Join": [ "", [ "com.amazonaws.", { "Ref": "AWS::Region" },
 ".s3" ] ] },
    "VpcId" : {"Ref" : "VPCID"}
  }
}
```

YAML

```
S3Endpoint:
  Type: AWS::EC2::VPCEndpoint
  Properties:
    PolicyDocument:
      Version: 2012-10-17
      Statement:
        - Effect: Allow
          Principal: '*'
          Action:
            - 's3:GetObject'
          Resource:
            - 'arn:aws:s3:::examplebucket/*'
    RouteTableIds:
      - !Ref routetableA
```

```
      - !Ref routetableB
    ServiceName: !Join
      - ''
      - - com.amazonaws.
        - !Ref 'AWS::Region'
        - .s3
    VpcId: !Ref VPCID
```

AWS::EC2::VPCEndpointConnectionNotification

Creates a connection notification for the specified VPC endpoint or VPC endpoint service. A connection notification notifies you of specific endpoint events. You must create an SNS topic to receive notifications. For more information, see CreateVpcEndpointConnectionNotification.

Topics

- Syntax (p. 1297)
- Properties (p. 1297)
- Return Values (p. 1298)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::VPCEndpointConnectionNotification",
  "Properties" : {
    "ConnectionEvents" : [ String, ... ],
    "VPCEndpointId" : String,
    "ServiceId" : String,
    "ConnectionNotificationArn" : String
  }
}
```

YAML

```
Type: "AWS::EC2::VPCEndpointConnectionNotification"
Properties:
  ConnectionEvents:
    - String
  VPCEndpointId: String
  ServiceId: String
  ConnectionNotificationArn: String
```

Properties

`ConnectionEvents`

One or more endpoint events for which to receive notifications. Valid values are `Accept`, `Connect`, `Delete`, and `Reject`.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`ConnectionNotificationArn`

The ARN of the SNS topic for the notifications.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ServiceId`

The ID of the endpoint service.

Required: No

Type: String

Update requires: No interruption (p. 120)

`VPCEndpointId`

The ID of the endpoint.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::EC2::VPCEndpointConnectionNotification` resource to the intrinsic `Ref` function, the function returns the ID of the connection notification.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::EC2::VPCEndpointService

Creates a VPC endpoint service configuration to which service consumers (AWS accounts, IAM users, and IAM roles) can connect. Service consumers can create an interface VPC endpoint to connect to your service. For more information, see CreateVpcEndpointServiceConfiguration.

Topics

- Syntax (p. 1298)
- Properties (p. 1299)
- Return Values (p. 1299)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::VPCEndpointService",
```

```
  "Properties" : {
    "NetworkLoadBalancerArns" : [ String, ... ],
    "AcceptanceRequired" : Boolean
  }
}
```

YAML

```
Type: "AWS::EC2::VPCEndpointService"
Properties:
  NetworkLoadBalancerArns:
    - String
  AcceptanceRequired: Boolean
```

Properties

`AcceptanceRequired`

Indicate whether requests from service consumers to create an endpoint to your service must be accepted. To accept a request, use AcceptVpcEndpointConnections.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`NetworkLoadBalancerArns`

The Amazon Resource Names (ARNs) of one or more Network Load Balancers for your service.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::EC2::VPCEndpointService` resource to the intrinsic `Ref` function, the function returns the ID of the VPC endpoint service configuration.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::EC2::VPCEndpointServicePermissions

Grant or revoke permissions for service consumers (IAM users, IAM roles, and AWS accounts) to connect to the VPC endpoint service. For more information, see ModifyVpcEndpointServicePermissions in the *Amazon EC2 API Reference*.

If you grant permissions to all principals, the service is public. Any users who know the name of a public service can send a request to attach an endpoint. If the service does not require manual approval, attachments are automatically approved.

Topics

- Syntax (p. 1300)

- Properties (p. 1300)
- Return Values (p. 1300)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EC2::VPCEndpointServicePermissions",
  "Properties" : {
    "AllowedPrincipals" : [ String, ... ],
    "ServiceId" : String
  }
}
```

YAML

```
Type: "AWS::EC2::VPCEndpointServicePermissions"
Properties:
  AllowedPrincipals:
    - String
  ServiceId: String
```

Properties

`AllowedPrincipals`

The Amazon Resource Names (ARN) of one or more principals (IAM users, IAM roles, and AWS accounts). Permissions are granted to the principals in this list. To grant permissions to all principals, specify an asterisk (*). Permissions are revoked for principals not in this list. If the list is empty, then all permissions are revoked.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`ServiceId`

The ID of the VPC endpoint service.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::EC2::VPCEndpointServicePermissions` resource to the intrinsic `Ref` function, the function returns the ID of the VPC endpoint service.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::EC2::VPCGatewayAttachment

Attaches a gateway to a VPC.

Topics

- Syntax (p. 1301)
- Properties (p. 1301)
- Return Values (p. 1302)
- Examples (p. 1302)
- See Also (p. 1303)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::VPCGatewayAttachment",
   "Properties" : {
      "InternetGatewayId (p. 1301)" : String,
      "VpcId (p. 1301)" : String,
      "VpnGatewayId (p. 1302)" : String
   }
}
```

YAML

```
Type: AWS::EC2::VPCGatewayAttachment
Properties:
  InternetGatewayId (p. 1301): String
  VpcId (p. 1301): String
  VpnGatewayId (p. 1302): String
```

Properties

`InternetGatewayId`

The ID of the Internet gateway.

Required: Conditional You must specify either `InternetGatewayId` or `VpnGatewayId`, but not both.

Type: String

Update requires: No interruption (p. 120)

`VpcId`

The ID of the VPC to associate with this gateway.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`VpnGatewayId`

The ID of the virtual private network (VPN) gateway to attach to the VPC.

Required: Conditional You must specify either `InternetGatewayId` or `VpnGatewayId`, but not both.

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

To attach both an Internet gateway and a VPN gateway to a VPC, you must specify two separate `AWS::EC2::VPCGatewayAttachment` resources:

JSON

```
"AttachGateway" : {
   "Type" : "AWS::EC2::VPCGatewayAttachment",
   "Properties" : {
      "VpcId" : { "Ref" : "VPC" },
      "InternetGatewayId" : { "Ref" : "myInternetGateway" }
   }
},

"AttachVpnGateway" : {
   "Type" : "AWS::EC2::VPCGatewayAttachment",
   "Properties" : {
      "VpcId" : { "Ref" : "VPC" },
      "VpnGatewayId" : { "Ref" : "myVPNGateway" }
   }
}
```

YAML

```
AttachGateway:
  Type: AWS::EC2::VPCGatewayAttachment
  Properties:
    VpcId:
      Ref: VPC
    InternetGatewayId:
      Ref: myInternetGateway
AttachVpnGateway:
  Type: AWS::EC2::VPCGatewayAttachment
  Properties:
    VpcId:
      Ref: VPC
    VpnGatewayId:
      Ref: myVPNGateway
```

See Also

- AttachVpnGateway in the *Amazon EC2 API Reference*.

AWS::EC2::VPCPeeringConnection

A VPC peering connection enables a network connection between two virtual private clouds (VPCs) so that you can route traffic between them using a private IP address. For more information about VPC peering and its limitations, see VPC Peering Overview in the *Amazon VPC Peering Guide*.

> **Note**
> You can create a peering connection with another AWS account. For a detailed walkthrough, see Walkthrough: Peer with an Amazon VPC in Another AWS Account (p. 243).

Topics

- Syntax (p. 1303)
- Properties (p. 1303)
- Return Values (p. 1304)
- Examples (p. 1305)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::VPCPeeringConnection",
   "Properties" : {
      "PeerVpcId" : String,
      "Tags" : [ Resource Tag, ... ],
      "VpcId" : String,
      "PeerOwnerId" : String,
      "PeerRegion" : String,
      "PeerRoleArn" :  String
   }
}
```

YAML

```
Type: AWS::EC2::VPCPeeringConnection
Properties:
  PeerVpcId: String
  Tags:
    - Resource Tag
  VpcId: String
  PeerOwnerId: String
  PeerRegion: String
  PeerRoleArn:  String
```

Properties

`PeerVpcId`

The ID of the VPC with which you are creating the peering connection.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) for this resource.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

`VpcId`

The ID of the VPC that is requesting a peering connection.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`PeerOwnerId`

The AWS account ID of the owner of the VPC that you want to peer with.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PeerRegion`

The region code for the accepter VPC, if the accepter VPC is located in a region other than the region in which you make the request. The default is the region in which you make the request.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PeerRoleArn`

The Amazon Resource Name (ARN) of the VPC peer role for the peering connection in another AWS account.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following example template creates two VPCs to demonstrate how to configure a peering connection. For a VPC peering connection, you must create a VPC peering route for each VPC route table, as shown in the example by `PeeringRoute1` and `PeeringRoute2`. If you launch the template, you can connect to the `myInstance` instance using SSH, and then ping the `myPrivateInstance` instance although both instances are in separate VPCs.

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "Creates a VPC that and then creates a peering connection with an
 existing VPC that you specify.",
    "Parameters": {
        "EC2KeyPairName": {
            "Description": "Name of an existing EC2 KeyPair to enable SSH access to the
 instances",
            "Type": "AWS::EC2::KeyPair::KeyName",
            "ConstraintDescription" : "must be the name of an existing EC2 KeyPair."
        },

            "Type": "AWS::EC2::VPCPeeringConnection",
            "Properties": {
                "VpcId": {"Ref": "myVPC"},
                "PeerVpcId": {"Ref": "myPrivateVPC"}
            }
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Description: Creates a VPC that and then creates a peering connection with an existing
  VPC that you specify.
Parameters:
  EC2KeyPairName:
    Description: Name of an existing EC2 KeyPair to enable SSH access to the instances
    Type: AWS::EC2::KeyPair::KeyName
    ConstraintDescription: must be the name of an existing EC2 KeyPair.
  InstanceType:
    Description: EC2 instance type
    Type: String
    Default: t1.micro
    AllowedValues:
    - t1.micro
    - m1.small
    - m3.medium
    - m3.large
    - m3.xlarge
    - m3.2xlarge
    - c3.large
    - c3.xlarge
    - c3.2xlarge
    - c3.4xlarge
    - c3.8xlarge
    ConstraintDescription: must be a valid EC2 instance type.
  myVPCIDCIDRRange:
    Description: The IP address range for your new VPC.
    Type: String
    MinLength: '9'
    MaxLength: '18'
    Default: 10.1.0.0/16
    AllowedPattern: "(\\d{1,3})\\.(\\d{1,3})\\.(\\d{1,3})\\.(\\d{1,3})/(\\d{1,2})"
    ConstraintDescription: must be a valid IP CIDR range of the form x.x.x.x/x.
```

```
  myPrivateVPCIDCIDRRange:
    Description: The IP address range for your new Private VPC.
    Type: String
    MinLength: '9'
    MaxLength: '18'
    Default: 10.0.0.0/16
    AllowedPattern: "(\\d{1,3})\\.(\\d{1,3})\\.(\\d{1,3})\\.(\\d{1,3})/(\\d{1,2})"
    ConstraintDescription: must be a valid IP CIDR range of the form x.x.x.x/x.
  EC2SubnetCIDRRange:
    Description: The IP address range for a subnet in myPrivateVPC.
    Type: String
    MinLength: '9'
    MaxLength: '18'
    Default: 10.0.0.0/24
    AllowedPattern: "(\\d{1,3})\\.(\\d{1,3})\\.(\\d{1,3})\\.(\\d{1,3})/(\\d{1,2})"
    ConstraintDescription: must be a valid IP CIDR range of the form x.x.x.x/x.
  EC2PublicSubnetCIDRRange:
    Description: The IP address range for a subnet in myVPC.
    Type: String
    MinLength: '9'
    MaxLength: '18'
    Default: 10.1.0.0/24
    AllowedPattern: "(\\d{1,3})\\.(\\d{1,3})\\.(\\d{1,3})\\.(\\d{1,3})/(\\d{1,2})"
    ConstraintDescription: must be a valid IP CIDR range of the form x.x.x.x/x.

AWS::EC2::VPNConnection

Creates a new VPN connection between an existing virtual private gateway and a VPN customer gateway.

For more information, see CreateVpnConnection in the *Amazon EC2 API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::VPNConnection",
   "Properties" : {
      "Type (p. 1313)" : String,
      "CustomerGatewayId (p. 1313)" : GatewayID,
      "StaticRoutesOnly (p. 1314)" : Boolean,
      "Tags" :  [ Resource Tag, ... ],
      "VpnGatewayId (p. 1314)" : GatewayID,
      "VpnTunnelOptionsSpecifications" : [ VpnTunnelOptionsSpecification (p. 1315), ... ]
   }
}
```

YAML

```
Type: AWS::EC2::VPNConnection
Properties:
  Type (p. 1313): String
  CustomerGatewayId (p. 1313):
    GatewayID
  StaticRoutesOnly (p. 1314): Boolean
  Tags:
    - Resource Tag
  VpnGatewayId (p. 1314):
    GatewayID
  VpnTunnelOptionsSpecifications:
    - VpnTunnelOptionsSpecification (p. 1315)
```

Properties

`Type`

The type of VPN connection this virtual private gateway supports.

Example: "ipsec.1"

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`CustomerGatewayId`

The ID of the customer gateway. This can either be an embedded JSON object or a reference to a Gateway ID.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`StaticRoutesOnly`

Indicates whether the VPN connection requires static routes.

Required: Conditional. If you are creating a VPN connection for a device that does not support Border Gateway Protocol (BGP), you must specify `true`.

Type: Boolean

Update requires: Replacement (p. 121)

`Tags`

The tags that you want to attach to the resource.

Required: No

Type: Resource Tag (p. 2258).

Update requires: No interruption (p. 120)

`VpnGatewayId`

The ID of the virtual private gateway. This can either be an embedded JSON object or a reference to a Gateway ID.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`VpnTunnelOptionsSpecifications`

The tunnel options for the VPN connection. Duplicates not allowed.

Required: No

Type: List of VpnTunnelOptionsSpecification (p. 1315)

Update requires: Replacement (p. 121)

Return Value

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyVPNConnection" }
```

For the VPNConnection with the logical ID "MyVPNConnection", `Ref` will return the VPN connection's resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Template Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
```

```
      "myVPNConnection" : {
         "Type" : "AWS::EC2::VPNConnection",
         "Properties" : {
            "Type" : "ipsec.1",
         "StaticRoutesOnly" : "true",
            "CustomerGatewayId" : {"Ref" : "myCustomerGateway"},
            "VpnGatewayId" : {"Ref" : "myVPNGateway"}
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  myVPNConnection:
    Type: AWS::EC2::VPNConnection
    Properties:
      Type: ipsec.1
      StaticRoutesOnly: true
      CustomerGatewayId:
        !Ref myCustomerGateway
      VpnGatewayId:
        !Ref myVPNGateway
```

See Also

- VpnConnection in the *Amazon EC2 API Reference*

Amazon EC2 VPNConnection VpnTunnelOptionsSpecification

The `VpnTunnelOptionsSpecification` property type configures tunnel options for an EC2 VPN connection.

`VpnTunnelOptionsSpecification` is a property of the AWS::EC2::VPNConnection (p. 1313) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "PreSharedKey" : String,
  "TunnelInsideCidr" : String
}
```

YAML

```
PreSharedKey: String
TunnelInsideCidr: String
```

Properties

`PreSharedKey`

The pre-shared key (PSK) to establish initial authentication between the virtual private gateway and customer gateway.

Constraints: Allowed characters are alphanumeric characters and ._. Must be between 8 and 64 characters in length and cannot start with zero (0).

Required: No

Type: String

Update requires: Replacement (p. 121)

`TunnelInsideCidr`

The range of inside IP addresses for the tunnel. Any specified CIDR blocks must be unique across all VPN connections that use the same virtual private gateway.

Constraints: A size /30 CIDR block from the `169.254.0.0/16` range. The following CIDR blocks are reserved and cannot be used:

- `169.254.0.0/30`
- `169.254.1.0/30`
- `169.254.2.0/30`
- `169.254.3.0/30`
- `169.254.4.0/30`
- `169.254.5.0/30`
- `169.254.169.252/30`

Required: No

Type: String

Update requires: Replacement (p. 121)

See Also

- VpnTunnelOptionsSpecification in the *Amazon EC2 API Reference*

AWS::EC2::VPNConnectionRoute

A static route that is associated with a VPN connection between an existing virtual private gateway and a VPN customer gateway. The static route allows traffic to be routed from the virtual private gateway to the VPN customer gateway.

Topics

- Syntax (p. 1316)
- Properties (p. 1317)
- Return Values (p. 1317)
- Example (p. 1317)
- See Also (p. 1318)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
   "Type" : "AWS::EC2::VPNConnectionRoute",
   "Properties" : {
      "DestinationCidrBlock (p. 1317)" : String,
      "VpnConnectionId (p. 1317)" : String
   }
}
```

YAML

```
Type: AWS::EC2::VPNConnectionRoute
Properties:
  DestinationCidrBlock (p. 1317): String
  VpnConnectionId (p. 1317): String
```

Properties

`DestinationCidrBlock`

The CIDR block that is associated with the local subnet of the customer network.

Required: Yes.

Type: String

Update requires: Replacement (p. 121)

`VpnConnectionId`

The ID of the VPN connection.

Required: Yes.

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
"MyConnectionRoute0" : {
   "Type" : "AWS::EC2::VPNConnectionRoute",
   "Properties" : {
      "DestinationCidrBlock" : "10.0.0.0/16",
      "VpnConnectionId" : {"Ref" : "Connection0"}
   }
}
```

YAML

```
MyConnectionRoute0:
```

```
  Type: AWS::EC2::VPNConnectionRoute
  Properties:
    DestinationCidrBlock: 10.0.0.0/16
    VpnConnectionId:
      !Ref Connection0
```

See Also

- CreateVpnConnectionRoute in the *Amazon EC2 API Reference*.

AWS::EC2::VPNGateway

Creates a virtual private gateway. A virtual private gateway is the VPC-side endpoint for your VPN connection.

Topics

- Syntax (p. 1318)
- Properties (p. 1318)
- Return Value (p. 1319)
- Example (p. 1319)
- See Also (p. 1320)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::VPNGateway",
   "Properties" : {
      "AmazonSideAsn" : Long,
      "Type (p. 1319)" : String,
      "Tags (p. 1319)" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::EC2::VPNGateway
Properties:
  AmazonSideAsn: Long
  Type (p. 1319): String
  Tags (p. 1319):
    Resource Tag
```

Properties

`AmazonSideAsn`

The private Autonomous System Number (ASN) for the Amazon side of a BGP session.

Required: No

Type: Long

Update requires: Replacement (p. 121)

`Type`

The type of VPN connection this virtual private gateway supports. The only valid value is `"ipsec.1"`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) for this resource.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

Return Value

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyVPNGateway" }
```

For the VPN gateway with the logical ID "MyVPNGateway", `Ref` will return the gateway's resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myVPNGateway" : {
         "Type" : "AWS::EC2::VPNGateway",
         "Properties" : {
            "Type" : "ipsec.1",
            "Tags" : [ { "Key" : "Use", "Value" : "Test" } ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
```

```
  myVPNGateway:
    Type: AWS::EC2::VPNGateway
    Properties:
      Type: ipsec.1
      Tags:
        -
          Key: Use
          Value: Test
```

See Also

- CreateVpnGateway in the *Amazon EC2 API Reference*.

AWS::EC2::VPNGatewayRoutePropagation

Enables a virtual private gateway (VGW) to propagate routes to the routing tables of a VPC.

> **Note**
> If you reference a VPN gateway that is in the same template as your VPN gateway route propagation, you must explicitly declare a dependency on the VPN gateway attachment. The `AWS::EC2::VPNGatewayRoutePropagation` resource cannot use the VPN gateway until it has successfully attached to the VPC. Add a DependsOn (p. 2275) attribute in the `AWS::EC2::VPNGatewayRoutePropagation` resource to explicitly declare a dependency on the VPN gateway attachment.

Topics

- Syntax (p. 1320)
- Properties (p. 1321)
- Return Value (p. 1321)
- Example (p. 1321)
- See Also (p. 1321)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::EC2::VPNGatewayRoutePropagation",
   "Properties" : {
      "RouteTableIds (p. 1321)" : [ String, ... ],
      "VpnGatewayId (p. 1321)" : String
   }
}
```

YAML

```
Type: AWS::EC2::VPNGatewayRoutePropagation
Properties:
  RouteTableIds (p. 1321):
    - String
  VpnGatewayId (p. 1321): String
```

Properties

`RouteTableIds`

A list of routing table IDs that are associated with a VPC. The routing tables must be associated with the same VPC that the virtual private gateway is attached to.

Required: Yes

Type: List of route table IDs

Update requires: No interruption (p. 120)

`VpnGatewayId`

The ID of the virtual private gateway that is attached to a VPC. The virtual private gateway must be attached to the same VPC that the routing tables are associated with.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Value

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myVPNGatewayRouteProp" }
```

For the VPN gateway with the logical ID *`myVPNGatewayRouteProp`*, `Ref` will return the gateway's resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
"myVPNGatewayRouteProp" : {
  "Type" : "AWS::EC2::VPNGatewayRoutePropagation",
  "Properties" : {
    "RouteTableIds" : [{"Ref" : "PrivateRouteTable"}],
    "VpnGatewayId" : {"Ref" : "VPNGateway"}
  }
}
```

YAML

```
myVPNGatewayRouteProp:
  Type: AWS::EC2::VPNGatewayRoutePropagation
  Properties:
    RouteTableIds:
      - !Ref PrivateRouteTable
    VpnGatewayId:
      !Ref VPNGateway
```

Amazon Elastic Container Registry Resource Types Reference

This section contains reference information for all Amazon Elastic Container Registry (Amazon ECR) resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::ECR::data-type-name
```

Topics

- AWS::ECR::Repository (p. 1322)

AWS::ECR::Repository

The `AWS::ECR::Repository` resource creates an Amazon Elastic Container Registry (Amazon ECR) repository, where users can push and pull Docker images. For more information, see Amazon ECR Repositories in the *Amazon Elastic Container Registry User Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ECR::Repository",
  "Properties" : {
    "LifecyclePolicy" : LifecyclePolicy (p. 1325),
    "RepositoryName" : String,
    "RepositoryPolicyText" : JSON object
  }
}
```

YAML

```
Type: AWS::ECR::Repository
Properties:
  LifecyclePolicy:
    LifecyclePolicy (p. 1325)
  RepositoryName: String
  RepositoryPolicyText: JSON object
```

Properties

`LifecyclePolicy`

A lifecycle policy for the repository.

Required: No

Type: LifecyclePolicy (p. 1325)

Update requires: No interruption (p. 120)

`RepositoryName`

A name for the image repository. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the repository name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`RepositoryPolicyText`

A policy that controls who has access to the repository and which actions they can perform on it. For more information, see Amazon ECR Repository Policies in the *Amazon Elastic Container Registry User Guide*.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name, such as `test-repository`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

Returns the Amazon Resource Name (ARN) for the specified `AWS::ECR::Repository` resource. For example, `arn:aws:ecr:eu-west-1:123456789012:repository/test-repository`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

The following example creates a repository named `test-repository`. Its policy permits the users `Bob` and `Alice` to push and pull images. Note that the IAM users actually need to exist, or stack creation will fail.

JSON

```
"MyRepository": {
  "Type": "AWS::ECR::Repository",
```

```
  "Properties": {
    "RepositoryName" : "test-repository",
    "RepositoryPolicyText" : {
      "Version": "2008-10-17",
      "Statement": [
        {
          "Sid": "AllowPushPull",
          "Effect": "Allow",
          "Principal": {
            "AWS": [
              "arn:aws:iam::123456789012:user/Bob",
              "arn:aws:iam::123456789012:user/Alice"
            ]
          },
          "Action": [
            "ecr:GetDownloadUrlForLayer",
            "ecr:BatchGetImage",
            "ecr:BatchCheckLayerAvailability",
            "ecr:PutImage",
            "ecr:InitiateLayerUpload",
            "ecr:UploadLayerPart",
            "ecr:CompleteLayerUpload"
          ]
        }
      ]
    }
  }
}
```

YAML

```
MyRepository:
  Type: AWS::ECR::Repository
  Properties:
    RepositoryName: "test-repository"
    RepositoryPolicyText:
      Version: "2012-10-17"
      Statement:
        -
          Sid: AllowPushPull
          Effect: Allow
          Principal:
            AWS:
              - "arn:aws:iam::123456789012:user/Bob"
              - "arn:aws:iam::123456789012:user/Alice"
          Action:
            - "ecr:GetDownloadUrlForLayer"
            - "ecr:BatchGetImage"
            - "ecr:BatchCheckLayerAvailability"
            - "ecr:PutImage"
            - "ecr:InitiateLayerUpload"
            - "ecr:UploadLayerPart"
            - "ecr:CompleteLayerUpload"
```

The following example creates a repository with a lifecycle policy.

JSON

```
{
  "Parameters": {
    "lifecyclePolicyText": {
      "Type": "String"
```

```
    },
    "repositoryName": {
      "Type": "String"
    },
    "registryId": {
      "Type": "String"
    }
  },
  "Resources": {
    "MyRepository": {
      "Type": "AWS::ECR::Repository",
      "Properties": {
        "LifecyclePolicy": {
          "LifecyclePolicyText": {
            "Ref": "lifecyclePolicyText"
          },
          "RegistryId": {
            "Ref": "registryId"
          }
        },
        "RepositoryName": {
          "Ref": "repositoryName"
        }
      }
    }
  },
  "Outputs": {
    "Arn": {
      "Value": {
        "Fn::GetAtt": [
          "MyRepository",
          "Arn"
        ]
      }
    }
  }
}
```

YAML

```
Parameters:
  lifecyclePolicyText:
    Type: String
  repositoryName:
    Type: String
  registryId:
    Type: String
Resources:
  MyRepository:
    Type: AWS::ECR::Repository
    Properties:
      LifecyclePolicy:
        LifecyclePolicyText: !Ref lifecyclePolicyText
        RegistryId: !Ref registryId
      RepositoryName: !Ref repositoryName
Outputs:
  Arn:
    Value: !GetAtt MyRepository.Arn
```

Amazon Elastic Container Registry Repository LifecyclePolicy

The `LifecyclePolicy` property type specifies a lifecycle policy for an Amazon Elastic Container Registry (Amazon ECR) repository.

`LifecyclePolicy` is a property of the AWS::ECR::Repository (p. 1322) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "LifecyclePolicyText" : String,
  "RegistryId" : String
}
```

YAML

```
LifecyclePolicyText: String
RegistryId: String
```

Properties

`LifecyclePolicyText`

The JSON repository policy text to apply to the repository. The length must be between 100 and 10,240 characters.

Required: No

Type: String

Update requires: No interruption (p. 120)

`RegistryId`

The AWS account ID that's associated with the registry that contains the repository. If you don't specify a registry, the default registry is used.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- Creating a Lifecycle Policy in the *Amazon Elastic Container Registry User Guide*
- PutLifecyclePolicy in the *Amazon Elastic Container Registry API Reference*

Amazon Elastic Container Service Resource Types Reference

This section contains reference information for all Amazon Elastic Container Service (Amazon ECS) resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::ECS::data-type-name
```

Topics

- AWS::ECS::Cluster (p. 1327)
- AWS::ECS::Service (p. 1328)
- AWS::ECS::TaskDefinition (p. 1345)

AWS::ECS::Cluster

The `AWS::ECS::Cluster` resource creates an Amazon Elastic Container Service (Amazon ECS) cluster. This resource has no properties; use the Amazon ECS container agent to connect to the cluster. For more information, see Amazon ECS Container Agent in the *Amazon Elastic Container Service Developer Guide*.

Topics

- Syntax (p. 1327)
- Properties (p. 1327)
- Return Values (p. 1328)
- Example (p. 1328)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ECS::Cluster",
  "Properties" : {
    "ClusterName" : String
  }
}
```

YAML

```
Type: AWS::ECS::Cluster
Properties:
  ClusterName: String
```

Properties

`ClusterName`

A name for the cluster. If you don't specify a name, AWS CloudFormation generates a unique physical ID for the name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

In the following sample, the `Ref` function returns the name of the `MyECSCluster` cluster, such as `MyStack-MyECSCluster-NT5EUXTNTXXD`.

```
{ "Ref": "MyECSCluster" }
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The Amazon Resource Name (ARN) of the Amazon ECS cluster, such as `arn:aws:ecs:us-east-2:123456789012:cluster/MyECSCluster`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following sample declares an Amazon ECS cluster:

JSON

```
"MyCluster": {
  "Type": "AWS::ECS::Cluster"
}
```

YAML

```
MyCluster:
  Type: AWS::ECS::Cluster
```

AWS::ECS::Service

The `AWS::ECS::Service` resource creates an Amazon Elastic Container Service (Amazon ECS) service that runs and maintains the requested number of tasks and associated load balancers.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ECS::Service",
  "Properties" : {
```

```
    "Cluster" : String,
    "DeploymentConfiguration" : DeploymentConfiguration,
    "DesiredCount" : Integer,
    "HealthCheckGracePeriodSeconds" : Integer,
    "LaunchType" : String,
    "LoadBalancers" : [ Load Balancer Objects, ... ],
    "NetworkConfiguration" : NetworkConfiguration (p. 1342),
    "PlacementConstraints" : [ PlacementConstraints, ... ],
    "Role" : String,
    "PlacementStrategies" : [ PlacementStrategies, ... ],
    "PlatformVersion" : String,
    "SchedulingStrategy" : String,
    "ServiceName" : String,
    "ServiceRegistries" : [ ServiceRegistry (p. 1344), ... ,
    "TaskDefinition" : String
  }
}
```

YAML

```
Type: AWS::ECS::Service
Properties:
  Cluster: String
  DeploymentConfiguration:
    DeploymentConfiguration
  DesiredCount: Integer
  HealthCheckGracePeriodSeconds: Integer
  LaunchType: String
  LoadBalancers:
    - Load Balancer Objects, ...
  NetworkConfiguration:
    NetworkConfiguration (p. 1342)
  PlacementConstraints:
   - PlacementConstraints, ...
  PlacementStrategies:
   - PlacementStrategies, ...
  PlatformVersion: String
  Role: String
  SchedulingStrategy: String
  ServiceName: String
  ServiceRegistries:
   - ServiceRegistry (p. 1344)
  TaskDefinition: String
```

Properties

For more information on properties and valid parameters, see CreateService in the *Amazon Elastic Container Service API Reference*.

> **Note**
> When you use Auto Scaling or Amazon Elastic Compute Cloud (Amazon EC2) to create container instances for an Amazon ECS cluster, the Amazon ECS service resource must have a dependency on the Auto Scaling group or the Amazon EC2 instances. This makes the container instances available and associates them with the Amazon ECS cluster before AWS CloudFormation creates the Amazon ECS service.

`Cluster`

The name or Amazon Resource Name (ARN) of the cluster that you want to run your Amazon ECS service on. If you do not specify a cluster, Amazon ECS uses the default cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DeploymentConfiguration`

Configures how many tasks run during a deployment.

Required: No

Type: Amazon Elastic Container Service Service DeploymentConfiguration (p. 1340)

Update requires: No interruption (p. 120)

`DesiredCount`

The number of simultaneous tasks that you want to run on the cluster. Specify the tasks with the `TaskDefinition` property.

Required: Conditional. Required only when creating an Amazon ECS Service.

Type: Integer

Update requires: No interruption (p. 120)

`HealthCheckGracePeriodSeconds`

The period of time, in seconds, that the Amazon ECS service scheduler ignores unhealthy Elastic Load Balancing target health checks after a task has first started.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`LaunchType`

The launch type on which to run your service. If one is not specified, `EC2` will be used by default. Valid values include `EC2` and `FARGATE`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`LoadBalancers`

A list of load balancer objects to associate with the cluster. If you specify the `Role` property, `LoadBalancers` must be specified as well. For information about the number of load balancers that you can specify per service, see Service Load Balancing in the *Amazon Elastic Container Service Developer Guide*.

Required: Conditional

Type: List of Amazon Elastic Container Service Service LoadBalancers (p. 1341)

Update requires: Replacement (p. 121)

`NetworkConfiguration`

The network configuration for the service. This parameter is required for task definitions that use the `awsvpc` network mode to receive their own Elastic Network Interface, and it is not supported for other network modes. For more information, see Task Networking in the *Amazon Elastic Container Service Developer Guide*.

Required: No

Type: NetworkConfiguration (p. 1342)

Update requires: No interruption (p. 120)

`PlacementConstraints`

The placement constraints for the tasks in the service.

Required: No

Type: Amazon Elastic Container Service Service PlacementConstraint (p. 1342)

Update requires: Replacement (p. 121)

`PlacementStrategies`

The placement strategies that determine how tasks for the service are placed.

Required: No

Type: Amazon Elastic Container Service Service PlacementStrategies (p. 1343)

Update requires: Replacement (p. 121)

`PlatformVersion`

The platform version on which to run your service. If one is not specified, the latest version will be used by default.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Role`

The name or ARN of an AWS Identity and Access Management (IAM) role that allows your Amazon ECS container agent to make calls to your load balancer.

> **Note**
> In some cases, you might need to add a dependency on the service role's policy. For more information, see IAM role policy in DependsOn Attribute (p. 2275).

Required: No

Type: String

Update requires: Replacement (p. 121)

`SchedulingStrategy`

The scheduling strategy to use for the service.

There are two service scheduler strategies available:

- `REPLICA`: The replica scheduling strategy places and maintains the desired number of tasks across your cluster. By default, the service scheduler spreads tasks across Availability Zones. You can use task placement strategies and constraints to customize task placement decisions.
- `DAEMON`: The daemon scheduling strategy deploys exactly one task on each container instance in your cluster. When using this strategy, do not specify a desired number of tasks or any task placement strategies.

Valid values include `REPLICA` and `DAEMON`.

Note
Fargate tasks do not support the `DAEMON` scheduling strategy

Required: No

Type: String

Update requires: Replacement (p. 121)

`ServiceName`

The name of your service. The name is limited to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores. Service names must be unique within a cluster, but you can have similarly named services in multiple clusters within a region or across multiple regions.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ServiceRegistries`

Details of the service registry.

Required: No

Type: ServiceRegistry (p. 1344)

Update requires: Replacement (p. 121)

`TaskDefinition`

The ARN of the task definition (including the revision number) that you want to run on the cluster, such as `arn:aws:ecs:us-east-1:123456789012:task-definition/mytask:3`. You can't use `:latest` to specify a revision because it's ambiguous. For example, if AWS CloudFormation needed to roll back an update, it wouldn't know which revision to roll back to.

Required: Yes

Type: String

Update requires: Some interruptions (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the ARN.

In the following sample, the `Ref` function returns the ARN of the `MyECSService` service, such as `arn:aws:ecs:us-west-2:123456789012:service/sample-webapp`.

```
{ "Ref": "MyECSService" }
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Name`

The name of the Amazon ECS service, such as `sample-webapp`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Define a Basic Amazon ECS Service

The following examples define an Amazon ECS service that uses a cluster and task definition that are declared elsewhere in the same template.

JSON

```
"WebApp": {
  "Type": "AWS::ECS::Service",
  "Properties" : {
    "Cluster": { "Ref": "cluster" },
    "DesiredCount": { "Ref": "desiredcount" },
    "TaskDefinition" : { "Ref": "taskdefinition" }
  }
}
```

YAML

```
WebApp:
  Type: AWS::ECS::Service
  Properties:
    Cluster:
      Ref: "cluster"
    DesiredCount:
      Ref: "desiredcount"
    TaskDefinition:
      Ref: "taskdefinition"
```

Associate an Application Load Balancer with a Service

The following example associates an Application Load Balancer with an Amazon ECS service by referencing an `AWS::ElasticLoadBalancingV2::TargetGroup` resource.

> **Note**
> The Amazon ECS service requires an explicit dependency on the Application load balancer listener rule and the Application load balancer listener. This prevents the service from starting before the listener is ready.

JSON

```
"service" : {
  "Type" : "AWS::ECS::Service",
  "DependsOn": ["Listener"],
  "Properties" : {
    "Role" : { "Ref" : "ECSServiceRole" },
    "TaskDefinition" : { "Ref" : "taskdefinition" },
    "DesiredCount" : "1",
    "LoadBalancers" : [{
      "TargetGroupArn" : { "Ref" : "TargetGroup" },
      "ContainerPort" : "80",
      "ContainerName" : "sample-app"
    }],
```

```
    "Cluster" : { "Ref" : "ECSCluster" }
  }
}
```

YAML

```
service:
  Type: AWS::ECS::Service
  DependsOn:
  - Listener
  Properties:
    Role:
      Ref: ECSServiceRole
    TaskDefinition:
      Ref: taskdefinition
    DesiredCount: 1
    LoadBalancers:
    - TargetGroupArn:
        Ref: TargetGroup
      ContainerPort: 80
      ContainerName: sample-app
    Cluster:
      Ref: ECSCluster
```

Define a Service with a Health Check Grace Period

The following example defines a service with a parameter that enables users to specify how many seconds that the Amazon ECS service scheduler should ignore unhealthy Elastic Load Balancing target health checks after a task has first started.

JSON

```
{
  "AWSTemplateFormatVersion" : "2010-09-09",
  "Description" : "Creating ECS service",
  "Parameters": {
    "AppName": {
      "Type":"String",
      "Description": "Name of app requiring ELB exposure",
      "Default": "simple-app"
    },
    "AppContainerPort": {
      "Type":"Number",
      "Description": "Container port of app requiring ELB exposure",
      "Default": "80"
    },
    "AppHostPort": {
      "Type":"Number",
      "Description": "Host port of app requiring ELB exposure",
      "Default": "80"
    },
    "ServiceName": {
      "Type": "String"
    },
    "LoadBalancerName": {
      "Type": "String"
    },
    "HealthCheckGracePeriodSeconds": {
      "Type": "String"
    }
  },
  "Resources": {
    "cluster": {
```

```
      "Type": "AWS::ECS::Cluster"
    },
    "taskdefinition": {
      "Type": "AWS::ECS::TaskDefinition",
      "Properties" : {
        "ContainerDefinitions" : [
          {
            "Name": {"Ref": "AppName"},
            "MountPoints": [
              {
                "SourceVolume": "my-vol",
                "ContainerPath": "/var/www/my-vol"
              }
            ],
            "Image":"amazon/amazon-ecs-sample",
            "Cpu": "10",
            "PortMappings":[
              {
                "ContainerPort": {"Ref":"AppContainerPort"},
                "HostPort": {"Ref":"AppHostPort"}
              }
            ],
            "EntryPoint": [
              "/usr/sbin/apache2",
              "-D",
              "FOREGROUND"
            ],
            "Memory":"500",
            "Essential": "true"
          },
          {
            "Name": "busybox",
            "Image": "busybox",
            "Cpu": "10",
            "EntryPoint": [
              "sh",
              "-c"
            ],
            "Memory": "500",
            "Command": [
              "/bin/sh -c \"while true; do /bin/date > /var/www/my-vol/date; sleep 1; done
\""
            ],
            "Essential" : "false",
            "VolumesFrom": [
              {
                "SourceContainer": {"Ref":"AppName"}
              }
            ]
          }
        ],
        "Volumes": [
          {
            "Host": {
              "SourcePath": "/var/lib/docker/vfs/dir/"
            },
            "Name": "my-vol"
          }
        ]
      }
    },
    "service": {
      "Type": "AWS::ECS::Service",
      "Properties" : {
        "Cluster": {"Ref": "cluster"},
        "DeploymentConfiguration": {
```

```
          "MaximumPercent": 200,
          "MinimumHealthyPercent": 100
        },
        "DesiredCount": 0,
        "HealthCheckGracePeriodSeconds": {"Ref": "HealthCheckGracePeriodSeconds"},
        "LoadBalancers": [{
          "ContainerName": {"Ref" : "AppName"},
          "ContainerPort": {"Ref":"AppContainerPort"},
          "LoadBalancerName": {"Ref": "elb"}
        }],
        "PlacementStrategies": [{
          "Type" : "binpack",
          "Field": "memory"
        }, {
          "Type": "spread",
          "Field": "host"
        }],
        "PlacementConstraints": [{
          "Type": "memberOf",

More Info

- To use Application Auto Scaling to scale an Amazon ECS service in response to Amazon CloudWatch alarms, use the AWS::ApplicationAutoScaling::ScalableTarget (p. 624) and AWS::ApplicationAutoScaling::ScalingPolicy (p. 639) resources.
- To use an Application Load Balancer to distribute incoming application traffic across multiple targets, use the AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491), AWS::ElasticLoadBalancingV2::Listener (p. 1473), AWS::ElasticLoadBalancingV2::ListenerRule (p. 1480), and AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484) resources.
- For a complete sample template that shows how you can create an Amazon ECS cluster and service, see Amazon Elastic Container Service Template Snippets (p. 358).

Amazon Elastic Container Service Service AwsVpcConfiguration

`AwsVpcConfiguration` is a property of the AWS::ECS::Service (p. 1328) resource that specifies the subnets and security groups for an Amazon Elastic Container Service (Amazon ECS) task or service.

Syntax

JSON

```
{
  "AssignPublicIp" : String,
  "SecurityGroups" : [ String, ... ],
  "Subnets" : [ String, ... ]
}
```

YAML

```
AssignPublicIp: String
```

```
SecurityGroups:
   - String
Subnets:
   - String
```

Properties

`AssignPublicIp`

Valid values include `ENABLED` and `DISABLED`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SecurityGroups`

The security groups associated with the task or service. If you do not specify a security group, the default security group for the VPC is used.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Subnets`

The subnets associated with the Amazon ECS task or service.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

Amazon Elastic Container Service Service DeploymentConfiguration

`DeploymentConfiguration` is a property of the AWS::ECS::Service (p. 1328) resource that configures how many tasks run when you update a running Amazon Elastic Container Service (Amazon ECS) service.

Syntax

JSON

```
{
  "MaximumPercent" : Integer,
  "MinimumHealthyPercent" : Integer
}
```

YAML

```
MaximumPercent: Integer
MinimumHealthyPercent: Integer
```

Properties

`MaximumPercent`

The maximum number of tasks, specified as a percentage of the Amazon ECS service's `DesiredCount` value, that can run in a service during a deployment. To calculate the maximum

number of tasks, Amazon ECS uses this formula: the value of `DesiredCount` * (the value of the `MaximumPercent`/100), rounded down to the nearest integer value.

Required: No

Type: Integer

`MinimumHealthyPercent`

The minimum number of tasks, specified as a percentage of the Amazon ECS service's `DesiredCount` value, that must continue to run and remain healthy during a deployment. To calculate the minimum number of tasks, Amazon ECS uses this formula: the value of `DesiredCount` * (the value of the `MinimumHealthyPercent`/100), rounded up to the nearest integer value.

Required: No

Type: Integer

Amazon Elastic Container Service Service LoadBalancers

`LoadBalancers` is a property of the AWS::ECS::Service (p. 1328) resource that specifies the load balancer to associate with an Amazon Elastic Container Service (Amazon ECS) service.

Syntax

JSON

```
{
  "ContainerName" : String,
  "ContainerPort" : Integer,
  "LoadBalancerName" : String,
  "TargetGroupArn" : String
}
```

YAML

```
ContainerName: String
ContainerPort: Integer
LoadBalancerName: String
TargetGroupArn: String
```

Properties

`ContainerName`

The name of a container to use with the load balancer.

Required: Yes

Type: String

`ContainerPort`

The port number on the container to direct load balancer traffic to. Your container instances must allow ingress traffic on this port.

Required: Yes

Type: Integer

`LoadBalancerName`

The name of a Classic Load Balancer to associate with the Amazon ECS service.

Required: No

Type: String

`TargetGroupArn`

An Application load balancer target group Amazon Resource Name (ARN) to associate with the Amazon ECS service.

Required: No

Type: String

Amazon Elastic Container Service Service NetworkConfiguration

`NetworkConfiguration` is a property of the AWS::ECS::Service (p. 1328) resource that specifies the network configuration for an Amazon Elastic Container Service (Amazon ECS) task or service.

Syntax

JSON

```
{
  "AwsvpcConfiguration" : AwsVpcConfiguration (p. 1339)
}
```

YAML

```
AwsvpcConfiguration: AwsVpcConfiguration (p. 1339)
```

Properties

`AwsvpcConfiguration`

The VPC subnets and security groups associated with a task.

Required: No

Type: Amazon Elastic Container Service Service AwsVpcConfiguration (p. 1339)

Update requires: No interruption (p. 120)

Amazon Elastic Container Service Service PlacementConstraint

`PlacementConstraint` is a property of the AWS::ECS::Service (p. 1328) resource that specifies the placement constraints for the tasks in the service to associate with an Amazon Elastic Container Service (Amazon ECS) service.

Syntax

JSON

```
{
  "Type" : String,
  "Expression" : String
```

```
}
```

YAML

```
Type: String
Expression: String
```

Properties

`Type`

The type of constraint: `distinctInstance` or `memberOf`.

To ensure that each task in a particular group is running on a different container instance, use `distinctInstance`. To restrict the selection to a group of valid candidates, use `memberOf`. `distinctInstance` is not supported in task definitions.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Expression`

A cluster query language expression to apply to the constraint. If the constraint type is `distinctInstance`, you can't specify an expression. For more information, see Cluster Query Language in the *Amazon Elastic Container Service Developer Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

Amazon Elastic Container Service Service PlacementStrategies

The `PlacementStrategies` property describes how tasks for the Amazon Elastic Container Service (Amazon ECS) service are placed in an `AWS::ECS::Service` resource.

Syntax

JSON

```
{
  "Type" : String,
  "Field" : String,
}
```

YAML

```
Type: String
Field: String
```

Properties

`Type`

The type of placement strategy. Can be one of the following values: `random`, `spread`, or `binpack`.

The `random` placement strategy randomly places tasks on available candidates. The `spread` placement strategy spreads placement across available candidates evenly based on the field parameter. The `binpack` strategy places tasks on available candidates that have the least available amount of the resource that is specified with the field parameter. For example, if you `binpack` on memory, a task is placed on the instance with the least amount of remaining memory (but still enough to run the task).

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Field`

The field to apply the placement strategy against. For the `spread` placement strategy, valid values are `instanceId` (or `host`, which has the same effect), or any platform or custom attribute that is applied to a container instance, such as `attribute:ecs.availability-zone`.

For the `binpack` placement strategy, valid values are `cpu` and `memory`.

For the `random` placement strategy, this field is not used.

Required: No

Type: String

Update requires: Replacement (p. 121)

Amazon Elastic Container Service Service ServiceRegistry

The `ServiceRegistry` property type specifies details of the service registry.

`ServiceRegistry` is a property of the AWS::ECS::Service (p. 1328) resource.

Syntax

JSON

```
{
  "ContainerName" : String,
  "ContainerPort" : Integer,
  "Port" : Integer,
  "RegistryArn" : String
}
```

YAML

```
ContainerName: String
ContainerPort: Integer
Port: Integer
RegistryArn: String
```

Properties

`ContainerName`

The container name value, already specified in the task definition, to be used for your service discovery service. If the task definition that your service task specifies uses the bridge or host

network mode, you must specify a `containerName` and `containerPort` combination from the task definition. If the task definition that your service task specifies uses the awsvpc network mode and a type SRV DNS record is used, you must specify either a `containerName` and `containerPort` combination or a `port` value, but not both.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ContainerPort`

The port value, already specified in the task definition, to be used for your service discovery service. If the task definition your service task specifies uses the bridge or host network mode, you must specify a `containerName` and `containerPort` combination from the task definition. If the task definition your service task specifies uses the awsvpc network mode and a type SRV DNS record is used, you must specify either a `containerName` and `containerPort` combination or a `port` value, but not both.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`Port`

The port value used if your service discovery service specified an SRV record.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`RegistryArn`

The Amazon Resource Name (ARN) of the service registry. The currently supported service registry is Amazon Route 53 auto naming.

Required: No

Type: String

Update requires: Replacement (p. 121)

See Also

- ServiceRegistry in the *Amazon Elastic Container Service API Reference*

AWS::ECS::TaskDefinition

The `AWS::ECS::TaskDefinition` resource describes the container and volume definitions of an Amazon Elastic Container Service (Amazon ECS) task. You can specify which Docker images to use, the required resources, and other configurations related to launching the task definition through an Amazon ECS service or task.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ECS::TaskDefinition",
  "Properties" : {
    "Volumes" : [ Volume Definition, ... ],
    "Cpu" : String,
    "ExecutionRoleArn" : String,
    "Family" : String,
    "Memory" : String,
    "NetworkMode" : String,
    "PlacementConstraints" : [ TaskDefinitionPlacementConstraint, ... ],
    "RequiresCompatibilities" : [ String, ... ],
    "TaskRoleArn" : String,
    "ContainerDefinitions" : [ Container Definition, ... ]
  }
}
```

YAML

```
Type: AWS::ECS::TaskDefinition
Properties:
  Volumes:
    - Volume Definition
  Cpu: String
  ExecutionRoleArn: String
  Family: String
  Memory: String
  NetworkMode: String
  PlacementConstraints:
    - TaskDefinitionPlacementConstraint
  RequiresCompatibilities:
    - String
  TaskRoleArn: String
  ContainerDefinitions:
    - Container Definition
```

Properties

For more information on properties and valid parameters, see RegisterTaskDefinition in the *Amazon Elastic Container Service API Reference*.

`ContainerDefinitions`

A list of container definitions in JSON format that describes the containers that make up your task.

Required: Yes

Type: List of Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352)

Update requires: Replacement (p. 121)

`Cpu`

The number of `cpu` units used by the task. If using the EC2 launch type, this field is optional. Supported values are between `128` CPU units (`0.125` vCPUs) and `10240` CPU units (`10` vCPUs). If you are using the Fargate launch type, this field is required and you must use one of the following values, which determines your range of valid values for the `memory` parameter:

- 256 (.25 vCPU) - Available `memory` values: 0.5GB, 1GB, 2GB
- 512 (.5 vCPU) - Available `memory` values: 1GB, 2GB, 3GB, 4GB
- 1024 (1 vCPU) - Available `memory` values: 2GB, 3GB, 4GB, 5GB, 6GB, 7GB, 8GB

- 2048 (2 vCPU) - Available `memory` values: Between 4GB and 16GB in 1GB increments
- 4096 (4 vCPU) - Available `memory` values: Between 8GB and 30GB in 1GB increments

Required: No

Type: String

Update requires: Replacement (p. 121)

`ExecutionRoleArn`

The Amazon Resource Name (ARN) of the task execution role that containers in this task can assume. All containers in this task are granted the permissions that are specified in this role.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Family`

The name of a family that this task definition is registered to. A *family* groups multiple versions of a task definition. Amazon ECS gives the first task definition that you registered to a family a revision number of 1. Amazon ECS gives sequential revision numbers to each task definition that you add.

> **Note**
> To use revision numbers when you update a task definition, specify this property. If you don't specify a value, AWS CloudFormation generates a new task definition each time that you update it.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Memory`

The amount (in MiB) of memory used by the task. If using the EC2 launch type, this field is optional and any value can be used. If you are using the Fargate launch type, this field is required and you must use one of the following values, which determines your range of valid values for the `cpu` parameter:

- 0.5GB, 1GB, 2GB - Available `cpu` values: 256 (.25 vCPU)
- 1GB, 2GB, 3GB, 4GB - Available `cpu` values: 512 (.5 vCPU)
- 2GB, 3GB, 4GB, 5GB, 6GB, 7GB, 8GB - Available `cpu` values: 1024 (1 vCPU)
- Between 4GB and 16GB in 1GB increments - Available `cpu` values: 2048 (2 vCPU)
- Between 8GB and 30GB in 1GB increments - Available `cpu` values: 4096 (4 vCPU)

Required: No

Type: String

Update requires: Replacement (p. 121)

`NetworkMode`

The Docker networking mode to use for the containers in the task, such as `none`, `bridge`, or `host`. For information about network modes, see `NetworkMode` in the Task Definition Parameters topic in the *Amazon Elastic Container Service Developer Guide*.

For Fargate launch types, you can specify `awsvpc` only. The `none`, `bridge`, or `host` option won't work for Fargate launch types.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PlacementConstraints`

The placement constraints for the tasks in the service.

Required: No

Type: Amazon Elastic Container Service Service PlacementConstraint (p. 1370)

Update requires: Replacement (p. 121)

`RequiresCompatibilities`

The launch type the task requires. If no value is specified, it will default to `EC2`. Valid values include `EC2` and `FARGATE`.

Required: No

Type: List of Strings

Update requires: Replacement (p. 121)

`TaskRoleArn`

The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role that grants containers in the task permission to call AWS APIs on your behalf. For more information, see IAM Roles for Tasks in the *Amazon Elastic Container Service Developer Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Volumes`

A list of volume definitions in JSON format for the volumes that you can use in your container definitions.

Required: No

Type: List of Amazon Elastic Container Service TaskDefinition Volumes (p. 1373)

Update requires: Replacement (p. 121)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the Amazon Resource Name (ARN).

In the following example, the `Ref` function returns the ARN of the `MyTaskDefinition` task, such as `arn:aws:ecs:us-west-2:123456789012:task-definition/TaskDefinitionFamily:1`.

```
{ "Ref": "MyTaskDefinition" }
```

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following example defines an Amazon ECS task definition, which includes two container definitions and one volume definition.

JSON

```
"taskdefinition": {
  "Type": "AWS::ECS::TaskDefinition",
  "Properties" : {
    "ContainerDefinitions" : [
    {
      "Name": {"Ref": "AppName"},
      "MountPoints": [
        {
          "SourceVolume": "my-vol",
          "ContainerPath": "/var/www/my-vol"
        }
      ],
      "Image":"amazon/amazon-ecs-sample",
      "Cpu": "10",
      "PortMappings":[
        {
          "ContainerPort": {"Ref":"AppContainerPort"},
          "HostPort": {"Ref":"AppHostPort"}
        }
      ],
      "EntryPoint": [
        "/usr/sbin/apache2",
        "-D",
        "FOREGROUND"
      ],
      "Memory":"500",
      "Essential": "true"
    },
    {
      "Name": "busybox",
      "Image": "busybox",
      "Cpu": "10",
      "EntryPoint": [
        "sh",
        "-c"
      ],
      "Memory": "500",
      "Command": [
        "/bin/sh -c \"while true; do /bin/date > /var/www/my-vol/date; sleep 1; done\""
      ],
      "Essential" : "false",
      "VolumesFrom": [
        {
          "SourceContainer": {"Ref":"AppName"}
        }
      ]
    }],
    "Volumes": [
    {
      "Host": {
        "SourcePath": "/var/lib/docker/vfs/dir/"
      },
      "Name": "my-vol"
    }]
  }
}
```

YAML

```

For a complete sample template that shows how you can create an Amazon ECS cluster and service, see Amazon Elastic Container Service Template Snippets (p. 358).

Amazon Elastic Container Service TaskDefinition ContainerDefinition

The `ContainerDefinition` property type describes the configuration of an Amazon Elastic Container Service (Amazon ECS) container. The container definitions are passed to the Docker daemon.

The `ContainerDefinitions` property of the AWS::ECS::TaskDefinition (p. 1345) resource contains a list of `ContainerDefinition` property types.

Syntax

JSON

```
{
  "Command" : [ String, ... ],
  "Cpu" : Integer,
  "DisableNetworking" : Boolean,
  "DnsSearchDomains" : [ String, ... ],
  "DnsServers" : [ String, ... ],
  "DockerLabels" : { String:String, ... },
  "DockerSecurityOptions" : [ String, ... ],
  "EntryPoint" : [ String, ... ],
  "Environment" : [ KeyValuePair (p. 1364), ... ],
  "Essential" : Boolean,
```

```
  "ExtraHosts" : [ HostEntry (p. 1363), ... ],
  "HealthCheck" : HealthCheck (p. 1360),
  "Hostname" : String,
  "Image" : String,
  "Links" : [ String, ... ],
  "LinuxParameters" : LinuxParameters (p. 1365),
  "LogConfiguration" : LogConfiguration (p. 1367),
  "Memory" : Integer,
  "MemoryReservation" : Integer,
  "MountPoints" : [ MountPoint (p. 1367), ... ],
  "Name" : String,
  "PortMappings" : [ PortMapping (p. 1368), ... ],
  "Privileged" : Boolean,
  "ReadonlyRootFilesystem" : Boolean,
  "RepositoryCredentials" : RepositoryCredentials (p. 1369),
  "Ulimits" : [ Ulimit (p. 1372), ... ],
  "User" : String,
  "VolumesFrom" : [ VolumeFrom (p. 1374), ... ],
  "WorkingDirectory" : String
}
```

YAML

```
Command:
  - String
Cpu: Integer
DisableNetworking: Boolean
DnsSearchDomains:

  RepositoryCredentials (p. 1369)
Ulimits:
```

```
  - Ulimit (p. 1372)
User: String
VolumesFrom:
  - VolumeFrom (p. 1374)
WorkingDirectory: String
```

Properties

For more information about each property, see Task Definition Parameters in the *Amazon Elastic Container Service Developer Guide*.

`Command`

The `CMD` value to pass to the container. For more information about the Docker `CMD` parameter, see https://docs.docker.com/engine/reference/builder/#cmd.

Required: No

Type: List of String values

`Cpu`

The minimum number of CPU units to reserve for the container. Containers share unallocated CPU units with other containers on the instance by using the same ratio as their allocated CPU units. For more information, see the `cpu` content for the ContainerDefinition data type in the *Amazon Elastic Container Service API Reference*.

Required: No

Type: Integer

`DisableNetworking`

Indicates whether networking is disabled within the container.

Required: No

Type: Boolean

`DnsSearchDomains`

A list of DNS search domains that are provided to the container. The domain names that the DNS logic looks up when a process attempts to access a bare unqualified hostname.

Required: No

Type: List of String values

`DnsServers`

A list of DNS servers that Amazon ECS provides to the container.

Required: No

Type: List of String values

`DockerLabels`

A key-value map of labels for the container.

Required: No

Type: Key-value pairs, with the name of the label as the key and the label value as the value.

`DockerSecurityOptions`

A list of custom labels for SELinux and AppArmor multi-level security systems. For more information, see the `dockerSecurityOptions` content for the ContainerDefinition data type in the *Amazon Elastic Container Service API Reference*.

Required: No

Type: List of String values

`EntryPoint`

The `ENTRYPOINT` value to pass to the container. For more information about the Docker `ENTRYPOINT` parameter, see https://docs.docker.com/engine/reference/builder/#entrypoint.

Required: No

Type: List of String values

`Environment`

The environment variables to pass to the container.

Required: No

Type: List of KeyValuePair (p. 1364) property types

`Essential`

Indicates whether the task stops if this container fails. If you specify **`true`** and the container fails, all other containers in the task stop. If you specify **`false`** and the container fails, none of the other containers in the task is affected. This value is **`true`** by default.

You must have at least one essential container in a task.

Required: No

Type: Boolean

`ExtraHosts`

A list of hostnames and IP address mappings to append to the `/etc/hosts` file on the container.

Required: No

Type: List of HostEntry (p. 1363) property types

`HealthCheck`

A container health check. Health check parameters that are specified in a container definition override any Docker health checks that exist in the container image (such as those specified in a parent image or from the image's Dockerfile).

Required: No

Type: HealthCheck (p. 1360)

`Hostname`

The name that Docker uses for the container hostname.

Required: No

Type: String

`Image`

The image to use for a container. The image is passed directly to the Docker daemon. You can use images in the Docker Hub registry or specify other repositories (*`repository-url`*/*`image`*:*`tag`*).

Required: Yes

Type: String

`Links`

The name of another container to connect to. With links, containers can communicate with each other without using port mappings.

Required: No

Type: List of String values

`LinuxParameters`

The Linux-specific options that are applied to the container.

Required: No

Type: LinuxParameters (p. 1365)

`LogConfiguration`

Configures a custom log driver for the container. For more information, see the `logConfiguration` content for the ContainerDefinition data type in the *Amazon Elastic Container Service API Reference*.

Required: No

Type: LogConfiguration (p. 1367)

`Memory`

The hard limit (in MiB) of memory to present to the container. If your container attempts to exceed the allocated memory, the container is terminated.

Required: Conditional. You must specify one or both of the `Memory` or `MemoryReservation` properties. If you specify both, the value for the `Memory` property must be greater than the value of the `MemoryReservation` property.

Type: Integer

`MemoryReservation`

The soft limit (in MiB) of memory to reserve for the container. When system memory is under contention, Docker attempts to keep the container memory within the limit. If the container requires more memory, it can consume up to the value specified by the `Memory` property or all of the available memory on the container instance—whichever comes first.

Required: Conditional. You must specify one or both of the `Memory` or `MemoryReservation` properties. If you specify both, the value for the `Memory` property must be greater than the value of the `MemoryReservation` property.

Type: Integer

`MountPoints`

The mount points for data volumes in the container.

Required: No

Type: List of MountPoint (p. 1367) property types

`Name`

A name for the container.

Required: Yes

Type: String

`PortMappings`

A mapping of the container port to a host port. Port mappings enable containers to access ports on the host container instance to send or receive traffic.

Required: No

Type: List of PortMapping (p. 1368) property types

`Privileged`

Indicates whether the container is given full access to the host container instance.

Required: No

Type: Boolean

`ReadonlyRootFilesystem`

Indicates whether the container's root file system is mounted as read only.

Required: No

Type: Boolean

`RepositoryCredentials`

The repository credentials for private registry authentication.

Required: No

Type: RepositoryCredentials (p. 1369)

`Ulimits`

A list of ulimits to set in the container. The ulimits set constraints on how many resources a container can consume so that it doesn't deplete all available resources on the host.

Required: No

Type: List of Ulimit (p. 1372) property types

`User`

The user name to use inside the container.

Required: No

Type: String

`VolumesFrom`

The data volumes to mount from another container.

Required: No

Type: List of VolumeFrom (p. 1374) property types

`WorkingDirectory`

The working directory in the container to run commands in.

Required: No

Type: String

See Also

- Task Definition Parameters in the *Amazon Elastic Container Service Developer Guide*

Amazon Elastic Container Service TaskDefinition Device

The `Device` property type specifies a device on a host container instance.

The `Devices` property of the LinuxParameters (p. 1365) contains a list of `Device` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ContainerPath" : String,
  "HostPath" : String,
  "Permissions" : [ String, ... ]
}
```

YAML

```
ContainerPath: String
HostPath: String
Permissions:
  - String
```

Properties

`ContainerPath`

The path inside the container to expose the host device to.

Required: No

Type: String

Update requires: Replacement (p. 121)

`HostPath`

The path for the device on the host container instance.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Permissions`

The explicit permissions to provide to the container for the device. By default, the container is able to `read`, `write`, and `mknod` the device.

Required: No

Type: List of String values

Valid values: `read`, `write`, and `mknod`

Update requires: Replacement (p. 121)

Amazon ECS TaskDefinition DockerVolumeConfiguration

The `DockerVolumeConfiguration` property type specifies the configuration of a Docker volume. This parameter is specified when using Docker volumes. Docker volumes are only supported when using the EC2 launch type. Windows containers only support the use of the `local` driver. To use bind mounts, specify a `host` instead.

`DockerVolumeConfiguration` is a property of the Amazon Elastic Container Service TaskDefinition Volumes (p. 1373) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Autoprovision" : Boolean,
  "Driver" : String,
  "DriverOpts" : [ String, ... ] ,
  "Labels" : [ String, ... ] ,
  "Scope" : String
}
```

YAML

```
Autoprovision: Boolean
Driver: String
DriverOpts
  - String
Labels
  - String
Scope: String
```

Properties

`Autoprovision`

If `true`, the Docker volume is created if it does not already exist. This field is only used if the scope is `shared`.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`Driver`

The Docker volume driver to use. The driver value must match the driver name provided by Docker because it is used for task placement. For more information, see DockerVolumeConfiguration in the *Amazon Elastic Container Service API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DriverOpts`

A map of Docker driver specific options passed through. For more information, see DockerVolumeConfiguration in the *Amazon Elastic Container Service API Reference*.

Duplicate values are not allowed.

Required: No

Type: List of Strings

Update requires: Replacement (p. 121)

`Labels`

Custom metadata to add to your Docker volume. For more information, see DockerVolumeConfiguration in the *Amazon Elastic Container Service API Reference*.

Duplicate values are not allowed.

Required: No

Type: List of String

Update requires: Replacement (p. 121)

`Scope`

The scope for the Docker volume which determines it's lifecycle. Docker volumes that are scoped to a `task` are automatically provisioned when the task starts and destroyed when the task stops. Docker volumes that are scoped as `shared` persist after the task stops.

Valid values include `shared` and `task`.

Required: No

Type: String

Update requires: Replacement (p. 121)

See Also

- DockerVolumeConfiguration in the *Amazon Elastic Container Service API Reference*

Amazon Elastic Container Service TaskDefinition HealthCheck

The `HealthCheck` property type specifies a container health check. Health check parameters that are specified in a container definition override any Docker health checks that exist in the container image (such as those specified in a parent image or from the image's Dockerfile).

`HealthCheck` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Command" : [ String, ... ] ,
  "Interval" : Integer,
  "Retries" : Integer,
  "StartPeriod" : Integer,
  "Timeout" : Integer
}
```

YAML

```
Command
  - String
Interval: Integer
Retries: Integer
StartPeriod: Integer
Timeout: Integer
```

Properties

`Command`

A string array representing the command that the container runs to determine if it is healthy. The string array must start with CMD to execute the command arguments directly, or CMD-SHELL to run the command with the container's default shell. For example:

["CMD-SHELL", "curl -f http://localhost/ || exit 1"]

An exit code of 0 indicates success, and non-zero exit code indicates failure.

Required: Yes

Type: List of String values

Update requires: Replacement (p. 121)

`Interval`

The time period in seconds between each health check execution. You may specify between 5 and 300 seconds. The default value is 30 seconds.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`Retries`

The number of times to retry a failed health check before the container is considered unhealthy. You may specify between 1 and 10 retries. The default value is 3 retries.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`StartPeriod`

The optional grace period within which to provide containers time to bootstrap before failed health checks count towards the maximum number of retries. You may specify between 0 and 300 seconds. The startPeriod is disabled by default.

> **Note**
> If a health check succeeds within the startPeriod, then the container is considered healthy and any subsequent failures count toward the maximum number of retries.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Timeout`

The time period in seconds to wait for a health check to succeed before it is considered a failure. You may specify between 2 and 60 seconds. The default value is 5 seconds.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

See Also

- HealthCheck in the *Amazon Elastic Container Service API Reference*

Amazon Elastic Container Service TaskDefinition Volumes Host

`Host` is a property of the Amazon Elastic Container Service TaskDefinition Volumes (p. 1373) property that specifies the data volume path on the host container instance.

Syntax

JSON

```
{
  "SourcePath" : String
}
```

YAML

```
SourcePath: String
```

Properties

For more information about each property, see Task Definition Parameters in the *Amazon Elastic Container Service Developer Guide*.

`SourcePath`

The data volume path on the host container instance.

If you don't specify this parameter, the Docker daemon assigns a path for you, but the data volume might not persist after the associated container stops running. If you do specify a path, the data volume persists at that location on the host container instance until you manually delete it.

Required: No

Type: String

Amazon Elastic Container Service TaskDefinition HostEntry

`HostEntry` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property that specifies the hostnames and IP address entries to add to the Amazon Elastic Container Service (Amazon ECS) container's `/etc/hosts` file.

Syntax

JSON

```
{
  "Hostname" : String,
  "IpAddress" : String
}
```

YAML

```
Hostname: String
IpAddress: String
```

Properties

`Hostname`

The hostname to use in the `/etc/hosts` file.

Required: Yes

Type: String

`IpAddress`

The IP address to use in the `/etc/hosts` file.

Required: Yes

Type: String

Amazon Elastic Container Service TaskDefinition KernelCapabilities

The `KernelCapabilities` property type specifies the Linux capabilities to add or drop from the default Docker configuration in an Amazon Elastic Container Service (Amazon ECS) container. For more information, see KernelCapabilities in the *Amazon Elastic Container Service API Reference*.

`KernelCapabilities` is a property of the LinuxParameters (p. 1365) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Add" : [ String, ... ],
  "Drop" : [ String, ... ]
}
```

YAML

```
Add:
  - String
Drop:
  - String
```

Properties

`Add`

The Linux capabilities to add to the default Docker configuration. This maps to `CapAdd` in the Create a container section of the *Docker Remote API* and the `--cap-add` option to docker run. For valid values, see KernelCapabilities in the *Amazon Elastic Container Service API Reference*.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`Drop`

The Linux capabilities to remove from the default Docker configuration. This maps to `CapDrop` in the Create a container section of the *Docker Remote API* and the `--cap-drop` option to docker run. For valid values, see KernelCapabilities in the *Amazon Elastic Container Service API Reference*.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

Amazon Elastic Container Service TaskDefinition KeyValuePair

`Environment` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property that specifies environment variables for a container.

Syntax

JSON

```
{
  "Name" : String,
  "Value" : String
}
```

YAML

```
Name: String
Value: String
```

Properties

For more information about each property, see Task Definition Parameters in the *Amazon Elastic Container Service Developer Guide*.

`Name`

The name of the environment variable.

Required: Yes

Type: String

`Value`

The value of the environment variable.

Required: Yes

Type: String

Amazon Elastic Container Service TaskDefinition LinuxParameters

The `LinuxParameters` property type specifies Linux-specific options to apply to an Amazon Elastic Container Service (Amazon ECS) container.

`LinuxParameters` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Capabilities" : KernelCapabilities (p. 1363),
  "Devices" : [ Device (p. 1358), ... ],
  "InitProcessEnabled" : Boolean,
  "SharedMemorySize" : Integer,
  "Tmpfs" : [ Tmpfs (p. 1371), ... ]
}
```

YAML

```
Capabilities:
  KernelCapabilities (p. 1363)
Devices:
  - Device (p. 1358)
InitProcessEnabled: Boolean
SharedMemorySize: String
Tmpfs:
  - Tmpfs (p. 1371)
```

Properties

`Capabilities`

The Linux capabilities for the container that are added to or dropped from the default configuration provided by Docker.

Required: No

Type: KernelCapabilities (p. 1363)

Update requires: Replacement (p. 121)

`Devices`

Any host devices to expose to the container. This maps to `Devices` in the Create a container section of the *Docker Remote API* and the `--device` option to docker run.

Required: No

Type: List of Device (p. 1358) property types

Update requires: Replacement (p. 121)

`InitProcessEnabled`

Indicates whether to run an `init` process inside the container that forwards signals and reaps processes. This maps to the `--init` option to docker run.

This property requires at least version 1.25 of the *Docker Remote API* on your container instance. To check the API version on your container instance, log in to your container instance and run the following command: `sudo docker version | grep "Server API version"`

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`SharedMemorySize`

The value for the size (in MiB) of the `/dev/shm` volume. This parameter maps to the `--shm-size` option to docker run.

> **Note**
> If you are using tasks that use the Fargate launch type, `SharedMemorySize` is not supported.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`Tmpfs`

The container path, mount options, and size (in MiB) of the tmpfs mount. This parameter maps to the `--tmpfs` option to docker run.

> **Note**
> If you are using tasks that use the Fargate launch type, `Tmpfs` is not supported.

Required: No

Type: List of Tmpfs (p. 1371) property types

Update requires: Replacement (p. 121)

See Also

- LinuxParameters in the *Amazon Elastic Container Service API Reference*

Amazon Elastic Container Service TaskDefinition LogConfiguration

`LogConfiguration` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property that configures a custom log driver for an Amazon Elastic Container Service (Amazon ECS) container.

Syntax

JSON

```
{
  "LogDriver" : String,
  "Options" : { String:String, ... }
}
```

YAML

```
LogDriver: String
Options:
  String: String
```

Properties

`LogDriver`

The log driver to use for the container. This parameter requires that your container instance uses Docker Remote API Version 1.18 or greater. For more information, see the `logDriver` content for the LogConfiguration data type in the *Amazon Elastic Container Service API Reference*.

Required: Yes

Type: String

`Options`

The configuration options to send to the log driver. This parameter requires that your container instance uses Docker Remote API Version 1.18 or greater.

Required: No

Type: Key-value pairs, with the option name as the key and the option value as the value.

Amazon Elastic Container Service TaskDefinition MountPoint

`MountPoints` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property that specifies the mount points for data volumes in a container.

Syntax

JSON

```
{
  "ContainerPath" : String,
  "SourceVolume" : String,
```

```
  "ReadOnly" : Boolean
}
```

YAML

```
ContainerPath: String
SourceVolume: String
ReadOnly: Boolean
```

Properties

For more information about each property, see Task Definition Parameters in the *Amazon Elastic Container Service Developer Guide*.

`ContainerPath`

The path on the container that indicates where you want to mount the volume.

Required: Yes

Type: String

`SourceVolume`

The name of the volume to mount.

Required: Yes

Type: String

`ReadOnly`

Indicates whether the container can write to the volume. If you specify **`true`**, the container has read-only access to the volume. If you specify **`false`**, the container can write to the volume. By default, the value is **`false`**.

Required: No

Type: Boolean

Amazon Elastic Container Service TaskDefinition PortMapping

`PortMappings` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property that maps a container port to a host port.

Syntax

JSON

```
{
  "ContainerPort" : Integer,
  "HostPort" : Integer,
  "Protocol" : String
}
```

YAML

```
ContainerPort: Integer
HostPort: Integer
Protocol: String
```

Properties

For more information about each property, see Task Definition Parameters in the *Amazon Elastic Container Service Developer Guide*.

`ContainerPort`

The port number on the container bound to the host port.

Required: Yes

Type: Integer

`HostPort`

The host port number on the container instance that you want to reserve for your container. You can specify a non-reserved host port for your container port mapping, omit the host port, or set the host port to `0`. If you specify a container port but no host port, your container host port is assigned automatically .

Don't specify a host port in the `49153` to `65535` port range; these ports are reserved for automatic assignment. Other reserved ports include `22` for SSH, `2375` and `2376` for Docker, and `51678` for the Amazon Elastic Container Service container agent. Don't specify a host port that is being used for a task—that port is reserved while the task is running.

Required: No

Type: Integer

`Protocol`

The protocol used for the port mapping. For valid values, see the `protocol` parameter in the *Amazon Elastic Container Service Developer Guide*. By default, AWS CloudFormation specifies `tcp`.

Required: No

Type: String

Amazon ECS TaskDefinition RepositoryCredentials

The `RepositoryCredentials` property type specifies the repository credentials for private registry authentication.

`RepositoryCredentials` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "CredentialsParameter" : String
}
```

YAML

```
CredentialsParameter: String
```

Properties

`CredentialsParameter`

The Amazon Resource Name (ARN) of the secret containing the private repository credentials.

> **Note**
> When using the Amazon ECS API, AWS CLI, or AWS SDK, if the secret exists in the same region as the task you are launching then you can use either the full ARN or name of the secret. When using the AWS Management Console, the full ARN of the secret must be specified.

Required: No

Type: String

Update requires: Replacement (p. 121)

See Also

- RepositoryCredentials in the *Amazon Elastic Container Service API Reference*

Amazon Elastic Container Service Service PlacementConstraint

`PlacementConstraint` is a property of the AWS::ECS::Service (p. 1328) resource that specifies the placement constraints for the tasks in the service to associate with an Amazon Elastic Container Service (Amazon ECS) service.

Syntax

JSON

```
{
  "Type" : String,
  "Expression" : String
}
```

YAML

```
Type: String
Expression: String
```

Properties

`Type`

The type of constraint: `distinctInstance` or `memberOf`.

To ensure that each task in a particular group is running on a different container instance, use `distinctInstance`. To restrict selection to a group of valid candidates, use `memberOf`. `distinctInstance` is not supported in task definitions.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Expression`

A cluster query language expression to apply to the constraint. If the constraint type is `distinctInstance`, you can't specify an expression. For more information, see Cluster Query Language in the *Amazon Elastic Container Service Developer Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

Amazon ECS TaskDefinition Tmpfs

The `Tmpfs` property type specifies the container path, mount options, and size of the tmpfs mount.

`Tmpfs` is a property of the Amazon Elastic Container Service TaskDefinition LinuxParameters (p. 1365) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ContainerPath" : String,
  "MountOptions" : [ String, ... ] ,
  "Size" : Integer
}
```

YAML

```
ContainerPath: String
MountOptions
  - String
Size: Integer
```

Properties

`ContainerPath`

The absolute file path where the tmpfs volume is to be mounted.

Required: No

Type: String

Update requires: Replacement (p. 121)

`MountOptions`

The list of tmpfs volume mount options. For a complete list of valid values, see Tmpfs in the *Amazon Elastic Container Service API Reference*.

Duplicate values are not allowed.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`Size`

The size (in MiB) of the tmpfs volume.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

See Also

- Tmpfs in the *Amazon Elastic Container Service API Reference*

Amazon Elastic Container Service TaskDefinition Ulimit

`Ulimit` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property that specifies resource limits for an Amazon Elastic Container Service (Amazon ECS) container.

Syntax

JSON

```
{
  "HardLimit" : Integer,
  "Name" : String,
  "SoftLimit" : Integer
}
```

YAML

```
HardLimit: Integer
Name: String
SoftLimit: Integer
```

Properties

`HardLimit`

The hard limit for the ulimit type.

Required: Yes

Type: Integer

`Name`

The type of ulimit. For valid values, see the `name` content for the Ulimit data type in the *Amazon Elastic Container Service API Reference*.

Required: No

Type: String

`SoftLimit`

The soft limit for the ulimit type.

Required: Yes

Type: Integer

Amazon Elastic Container Service TaskDefinition Volumes

`Volumes` is a property of the AWS::ECS::TaskDefinition (p. 1345) resource that specifies a list of data volumes, which your containers can then access.

Syntax

JSON

```
{
  "DockerVolumeConfiguration" : DockerVolumeConfiguration,
  "Host" : Host,
  "Name" : String
}
```

YAML

```
DockerVolumeConfiguration:
  DockerVolumeConfiguration
Host:
  Host
Name: String
```

Properties

For more information about each property, see Task Definition Parameters in the *Amazon Elastic Container Service Developer Guide*.

`DockerVolumeConfiguration`

Specifies the configuration of a Docker volume. This parameter is specified when using Docker volumes. Docker volumes are only supported when using the EC2 launch type. Windows containers only support the use of the `local` driver. To use bind mounts, specify a `host` instead.

Required: No

Type: Amazon ECS TaskDefinition DockerVolumeConfiguration (p. 1359)

`Host`

Determines whether your data volume persists on the host container instance and at the location where it is stored.

Required: No

Type: Amazon Elastic Container Service TaskDefinition Volumes Host (p. 1362)

`Name`

The name of the volume. To specify mount points in your container definitions, use the value of this property.

Required: Yes

Type: String

Amazon Elastic Container Service TaskDefinition VolumeFrom

`VolumesFrom` is a property of the Amazon Elastic Container Service TaskDefinition ContainerDefinition (p. 1352) property that mounts data volumes from other containers.

Syntax

JSON

```
{
  "SourceContainer" : String,
  "ReadOnly" : Boolean
}
```

YAML

```
SourceContainer: String
ReadOnly: Boolean
```

Properties

For more information about each property, see Task Definition Parameters in the *Amazon Elastic Container Service Developer Guide*.

`SourceContainer`

The name of the container that has the volumes to mount.

Required: Yes

Type: String

`ReadOnly`

Indicates whether the container can write to the volume. If you specify **`true`**, the container has read-only access to the volume. If you specify **`false`**, the container can write to the volume. By default, the value is **`false`**.

Required: No

Type: Boolean

Amazon Elastic File System Resource Types Reference

This section contains reference information for all Amazon Elastic File System resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::EFS::data-type-name
```

Topics

- AWS::EFS::FileSystem (p. 1375)

- AWS::EFS::MountTarget (p. 1379)

AWS::EFS::FileSystem

The `AWS::EFS::FileSystem` resource creates a new, empty file system in Amazon Elastic File System (Amazon EFS). You must create a mount target (AWS::EFS::MountTarget (p. 1379)) to mount your Amazon EFS file system on an Amazon Elastic Compute Cloud (Amazon EC2) instance. For more information, see the CreateFileSystem API in the *Amazon Elastic File System User Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EFS::FileSystem",
  "Properties" : {
    "Encrypted" : Boolean,
    "FileSystemTags" : [ FileSystemTags, ... ],
    "KmsKeyId" : String,
    "PerformanceMode" : String,
    "ProvisionedThroughputInMibps" : Double,
    "ThroughputMode" : String
  }
}
```

YAML

```
Type: AWS::EFS::FileSystem
Properties:
  Encrypted: Boolean
  FileSystemTags:
    - FileSystemTags
  KmsKeyId: String
  PerformanceMode: String
  ProvisionedThroughputInMibps: Double
  ThroughputMode: String
```

Properties

`FileSystemTags`

Tags to associate with the file system.

Required: No

Type: Amazon Elastic File System FileSystem FileSystemTags (p. 1378)

Update requires: No interruption (p. 120)

`Encrypted`

A boolean value that, if true, creates an encrypted file system. For more information, see CreateFileSystem in the *Amazon Elastic File System User Guide*.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`KmsKeyId`

The ID of the AWS KMS customer master key (CMK) to use to protect the encrypted file system. This parameter is only required if you want to use a non-default CMK. For more information, see CreateFileSystem in the *Amazon Elastic File System User Guide*.

Required: Conditional. This parameter is required if you use a non-default CMK.

Type: String

Update requires: Replacement (p. 121)

`PerformanceMode`

The performance mode of the file system. For valid values, see the `PerformanceMode` parameter for the CreateFileSystem action in the *Amazon Elastic File System User Guide*.

For more information about performance modes, see Amazon EFS Performance in the *Amazon Elastic File System User Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ProvisionedThroughputInMibps`

The throughput, measured in MiB/s, that you want to provision for a file system that you're creating. The limit on throughput is 1024 MiB/s. You can get these limits increased by contacting AWS Support. For more information, see Amazon EFS Limits That You Can Increase in the *Amazon Elastic File System User Guide*.

Valid Range: Minimum value of 0.0.

Required: No

Type: Double

Update requires: No interruption (p. 120)

`ThroughputMode`

The throughput mode for the file system to be created. There are two throughput modes to choose from for your file system: `bursting` and `provisioned`. You can decrease your file system's throughput in Provisioned Throughput mode or change between the throughput modes as long as it's been more than 24 hours since the last decrease or throughput mode change.

Valid Values: `bursting` and `provisioned`.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource ID, such as `fs-47a2c22e`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example declares an encrypted file system:

JSON

```
{
    "Resources": {
        "filesystem": {
            "Type": "AWS::EFS::FileSystem",
            "Properties": {
                "Encrypted": true,
                "KmsKeyId": {
                    "Fn::GetAtt": [
                        "key",
                        "Arn"
                    ]
                }
            }
        },
        "key": {
            "Type": "AWS::KMS::Key",
            "Properties": {
                "KeyPolicy": {
                    "Version": "2012-10-17",
                    "Id": "key-default-1",
                    "Statement": [
                        {
                            "Sid": "Allow administration of the key",
                            "Effect": "Allow",
                            "Principal": {
                                "AWS": {
                                    "Fn::Join": [
                                        "",
                                        [
                                            "arn:aws:iam::",
                                            {
                                                "Ref": "AWS::AccountId"
                                            },
                                            ":root"
                                        ]
                                    ]
                                }
                            },
                            "Action": [
                                "kms:*"
                            ],
                            "Resource": "*"
                        }
                    ]
                }
            }
        }
    },
    "Outputs": {
        "KeyId": {
            "Value": {
                "Fn::GetAtt": [
                    "key",
                    "Arn"
                ]
            }
        }
```

```
    }
}
```

YAML

```
Resources:
  filesystem:
    Type: AWS::EFS::FileSystem
    Properties:
      Encrypted: true
      KmsKeyId: !GetAtt
        - key
        - Arn
  key:
    Type: AWS::KMS::Key
    Properties:
      KeyPolicy:
        Version: 2012-10-17
        Id: key-default-1
        Statement:
          - Sid: Allow administration of the key
            Effect: Allow
            Principal:
              AWS: !Join
                - ''
                - - 'arn:aws:iam::'
                  - !Ref 'AWS::AccountId'
                  - ':root'
            Action:
              - 'kms:*'
            Resource: '*'
Outputs:
  KeyId:
    Value: !GetAtt
      - key
      - Arn
```

Additional Resources

For a complete sample template, see Amazon Elastic File System Sample Template (p. 374).

Amazon Elastic File System FileSystem FileSystemTags

`FileSystemTags` is a property of the AWS::EFS::FileSystem (p. 1375) resource that associates key-value pairs with a file system. You can use any of the following Unicode characters for keys and values: letters, digits, whitespace, _, ., /, =, +, and -.

Syntax

JSON

```
{
  "Key" : String,
  "Value" : String
}
```

YAML

```
Key: String
Value: String
```

Properties

`Key`

The key name of the tag. You can specify a value that is from 1 to 128 Unicode characters in length, but you cannot use the prefix `aws:`.

Required: No

Type: String

`Value`

The value of the tag key. You can specify a value that is from 0 to 128 Unicode characters in length.

Required: No

Type: String

AWS::EFS::MountTarget

The `AWS::EFS::MountTarget` resource creates a mount target for an Amazon Elastic File System (Amazon EFS) file system (AWS::EFS::FileSystem (p. 1375)). Use the mount target to mount file systems on Amazon Elastic Compute Cloud (Amazon EC2) instances.

For more information on creating a mount target for a file system, see CreateMountTarget in the *Amazon Elastic File System User Guide*. For a detailed overview of deploying EC2 instances associated with an Amazon EFS file system, see Amazon Elastic File System Sample Template (p. 374).

> **Note**
> EC2 instances and the mount target that they connect to must be in a VPC with DNS enabled.

Topics

- Syntax (p. 1379)
- Properties (p. 1380)
- Return Values (p. 1381)
- Template Example (p. 1381)
- Additional Resources (p. 1381)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EFS::MountTarget",
  "Properties" : {
    "FileSystemId" : String,
    "IpAddress" : String,
    "SecurityGroups" : [ String, ... ],
    "SubnetId" : String
  }
}
```

YAML

```
Type: AWS::EFS::MountTarget
```

```
Properties:
  FileSystemId: String
  IpAddress: String
  SecurityGroups:
    [ String, ... ]
  SubnetId: String
```

Properties

`FileSystemId`

The ID of the file system for which you want to create the mount target.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Before updating this property, stop EC2 instances that are using this mount target, and then restart them after the update is complete. This allows the instances to unmount the file system before the mount target is replaced. If you don't stop and restart them, instances or applications that are using those mounts might be disrupted when the mount target is deleted (uncommitted writes might be lost).

`IpAddress`

An IPv4 address that is within the address range of the subnet that is specified in the `SubnetId` property. If you don't specify an IP address, Amazon EFS automatically assigns an address that is within the range of the subnet.

Required: No

Type: String

Update requires: Replacement (p. 121)

Before updating this property, stop EC2 instances that are using this mount target, and then restart them after the update is complete. This allows the instances to unmount the file system before the mount target is replaced. If you don't stop and restart them, instances or applications that are using those mounts might be disrupted when the mount target is deleted (uncommitted writes might be lost).

`SecurityGroups`

A maximum of five VPC security group IDs that are in the same VPC as the subnet that is specified in the `SubnetId` property. For more information about security groups and mount targets, see Security in the *Amazon Elastic File System User Guide*.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`SubnetId`

The ID of the subnet in which you want to add the mount target.

> **Note**
> For each file system, you can create only one mount target per Availability Zone (AZ). All EC2 instances in an AZ share a single mount target for a file system. If you create multiple

mount targets for a single file system, do not specify a subnet that is an AZ that already has a mount target associated with the same file system.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Before updating this property, stop EC2 instances that are using this mount target and then restart them after the update is complete. That way the instances can unmount the file system before the mount target is replaced. If you don't stop and restart them, instances or applications that are using those mounts might be disrupted when the mount target is deleted (uncommitted writes might be lost).

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource ID, such as `fsmt-55a4413c`.

For more information about using the `Ref` function, see Ref (p. 2341).

Template Example

The following example declares a mount target that is associated with a file system, subnet, and security group, which are all declared in the same template. EC2 instances that are in the same AZ as the mount target can use the mount target to connect to the associated file system. For information about mounting file systems on EC2 instances, see Mounting File Systems in the *Amazon Elastic File System User Guide*.

JSON

```
"MountTarget": {
  "Type": "AWS::EFS::MountTarget",
  "Properties": {
    "FileSystemId": { "Ref": "FileSystem" },
    "SubnetId": { "Ref": "Subnet" },
    "SecurityGroups": [ { "Ref": "MountTargetSecurityGroup" } ]
  }
}
```

YAML

```
MountTarget:
  Type: AWS::EFS::MountTarget
  Properties:
    FileSystemId:
      Ref: "FileSystem"
    SubnetId:
      Ref: "Subnet"
    SecurityGroups:
      -
        Ref: "MountTargetSecurityGroup"
```

Additional Resources

For a complete sample template, see Amazon Elastic File System Sample Template (p. 374).

Amazon Elastic Container Service for Kubernetes Resource Types Reference

This section contains reference information for all Amazon Elastic Container Service for Kubernetes resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::EKS::data-type-name
```

Topics

- AWS::EKS::Cluster (p. 1382)

AWS::EKS::Cluster

The `AWS::EKS::Cluster` resource creates an Amazon EKS cluster control plane. The Amazon EKS cluster control plane consists of control plane instances that run the Kubernetes software, like `etcd` and the Kubernetes API server. The control plane runs in an account managed by AWS, and the Kubernetes API is exposed via the Amazon EKS endpoint associated with your cluster. For more information, see Clusters in the *Amazon EKS User Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EKS::Cluster",
  "Properties" : {
    "Name" : String,
    "ResourcesVpcConfig" : EKS Cluster ResourcesVpcConfig,
    "RoleArn" : String,
    "Version" : String
  }
}
```

YAML

```
Type: "AWS::EKS::Cluster"
Properties:
  Name: String
  ResourcesVpcConfig: EKS Cluster ResourcesVpcConfig
  RoleArn: String
  Version: String
```

Properties

`Name`

The name of the cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ResourcesVpcConfig`

The VPC subnets and security groups used by the cluster control plane. Amazon EKS VPC resources have specific requirements to work properly with Kubernetes. For more information, see Cluster VPC Considerations and Cluster Security Group Considerations in the *Amazon EKS User Guide*.

Required: Yes

Type: EKS Cluster ResourcesVpcConfig (p. 1384)

Update requires: Replacement (p. 121)

`RoleArn`

The Amazon Resource Name (ARN) of the IAM role that provides permissions for the Kubernetes control plane to make calls to AWS API operations on your behalf.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Version`

The Kubernetes server version for the cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::EKS::Cluster` resource to the intrinsic `Ref` function, the function returns the name of the cluster, such as `EKSCluster-NT5EUXTNTXXD`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The ARN of the cluster, such as `arn:aws:eks:us-west-2:666666666666:cluster/prod`.

`CertificateAuthorityData`

The `certificate-authority-data` for your cluster.

`Endpoint`

The endpoint for your Kubernetes API server, such as `https://5E1D0CEXAMPLEA591B746AFC5AB30262.yl4.us-west-2.eks.amazonaws.com`

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Create a Cluster

The following example creates an Amazon EKS cluster called `prod`.

JSON

```
{
  "Type": "AWS::EKS::Cluster",
  "Properties": {
    "Name": "prod",
    "Version": "1.10",
    "RoleArn": "arn:aws:iam::012345678910:role/eks-service-role-AWSServiceRoleForAmazonEKS-
EXAMPLEBQ4PI",
    "ResourcesVpcConfig": {
      "SecurityGroupIds": [
        "sg-6979fe18"
      ],
      "SubnetIds": [
        "subnet-6782e71e",

- CreateCluster in the *Amazon EKS API Reference*.

EKS Cluster ResourcesVpcConfig

The `ResourcesVpcConfig` property type specifies the VPC subnets and security groups used by the Amazon EKS cluster control plane. Amazon EKS VPC resources have specific requirements to work properly with Kubernetes. For more information, see Cluster VPC Considerations and Cluster Security Group Considerations in the *Amazon EKS User Guide*.

`ResourcesVpcConfig` is a property of the AWS::EKS::Cluster (p. 1382) resource type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SecurityGroupIds" : [ String, ... ] ,
  "SubnetIds" : [ String, ... ]
}
```

YAML

```
SecurityGroupIds:
  - String
SubnetIds:
  - String
```

Properties

`SecurityGroupIds`

Specify one or more security groups for the cross-account elastic network interfaces that Amazon EKS creates to use to allow communication between your worker nodes and the Kubernetes control plane.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SubnetIds`

Specify at least 2 subnets for your Amazon EKS worker nodes. Amazon EKS creates cross-account elastic network interfaces in these subnets to allow communication between your worker nodes and the Kubernetes control plane.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

See Also

- Clusters in the *Amazon EKS User Guide*.
- CreateCluster in the *Amazon EKS API Reference*.

Amazon ElastiCache Resource Types Reference

This section contains reference information for all Amazon ElastiCache resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::ElastiCache::data-type-name
```

Topics

- AWS::ElastiCache::CacheCluster (p. 1386)
- AWS::ElastiCache::ParameterGroup (p. 1393)
- AWS::ElastiCache::ReplicationGroup (p. 1395)
- AWS::ElastiCache::SecurityGroup (p. 1408)
- AWS::ElastiCache::SecurityGroupIngress (p. 1409)
- AWS::ElastiCache::SubnetGroup (p. 1410)

AWS::ElastiCache::CacheCluster

The AWS::ElastiCache::CacheCluster type creates an Amazon ElastiCache cache cluster.

Topics

- Syntax (p. 1386)
- Properties (p. 1387)
- Return Values (p. 1391)
- Template Snippets (p. 1392)
- See Also (p. 1393)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::ElastiCache::CacheCluster",
   "Properties" :
   {
      "AutoMinorVersionUpgrade (p. 1387)" : Boolean,
      "AZMode" : String,
      "CacheNodeType (p. 1387)" : String,
      "CacheParameterGroupName (p. 1388)" : String,
      "CacheSecurityGroupNames (p. 1388)" : [ String, ... ],
      "CacheSubnetGroupName (p. 1388)" : String,
      "ClusterName" : String,
      "Engine (p. 1388)" : String,
      "EngineVersion (p. 1389)" : String,
      "NotificationTopicArn (p. 1389)" : String,
      "NumCacheNodes (p. 1389)" : Integer,
      "Port (p. 1389)" : Integer,
      "PreferredAvailabilityZone (p. 1389)" : String,
      "PreferredAvailabilityZones" : [String, ... ],
      "PreferredMaintenanceWindow (p. 1390)" : String,
      "SnapshotArns (p. 1390)" : [String, ... ],
      "SnapshotName" : String,
      "SnapshotRetentionLimit" : Integer,
      "SnapshotWindow" : String,
      "Tags" : [Resource Tag, ...],
      "VpcSecurityGroupIds (p. 1391)" : [String, ...]
   }
}
```

YAML

```
Type: AWS::ElastiCache::CacheCluster
```

```
Properties:
  AutoMinorVersionUpgrade (p. 1387): Boolean
  AZMode: String
  CacheNodeType (p. 1387): String
  CacheParameterGroupName (p. 1388): String
  CacheSecurityGroupNames (p. 1388):
    - String
  CacheSubnetGroupName (p. 1388): String
  ClusterName: String
  Engine (p. 1388): String
  EngineVersion (p. 1389): String
  NotificationTopicArn (p. 1389): String
  NumCacheNodes (p. 1389): Integer
  Port (p. 1389): Integer
  PreferredAvailabilityZone (p. 1389): String
  PreferredAvailabilityZones:
    - String
  PreferredMaintenanceWindow (p. 1390): String
  SnapshotArns (p. 1390):
    - String
  SnapshotName: String
  SnapshotRetentionLimit: Integer
  SnapshotWindow: String
  Tags:
    - Resource Tag
  VpcSecurityGroupIds (p. 1391):
    - String
```

Properties

For valid values, see CreateCacheCluster in the *Amazon ElastiCache API Reference*.

`AutoMinorVersionUpgrade`

Indicates that minor engine upgrades will be applied automatically to the cache cluster during the maintenance window.

Required: No

Type: Boolean

Default: `true`

Update requires: No interruption (p. 120)

`AZMode`

For Memcached cache clusters, indicates whether the nodes are created in a single Availability Zone or across multiple Availability Zones in the cluster's region. For valid values, see CreateCacheCluster in the *Amazon ElastiCache API Reference*.

Required: Conditional. If you specify multiple Availability Zones in the `PreferredAvailabilityZones` property, you must specify cross Availability Zones for this property.

Type: String

Update requires: No interruption (p. 120)

`CacheNodeType`

The compute and memory capacity of nodes in a cache cluster.

Required: Yes

Type: String

Update requires: Some interruptions (p. 121)

`CacheParameterGroupName`

The name of the cache parameter group that is associated with this cache cluster.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`CacheSecurityGroupNames`

A list of cache security group names that are associated with this cache cluster. If your cache cluster is in a VPC, specify the `VpcSecurityGroupIds` property instead.

Required: Conditional: If your cache cluster isn't in a VPC, you must specify this property.

Type: List of String values

Update requires: No interruption (p. 120)

`CacheSubnetGroupName`

The cache subnet group that you associate with a cache cluster.

Required: Conditional. If you specified the `VpcSecurityGroupIds` property, you must specify this property.

Type: String

Update requires: Replacement (p. 121)

`ClusterName`

A name for the cache cluster. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the cache cluster. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

The name must contain 1 to 20 alphanumeric characters or hyphens. The name must start with a letter and cannot end with a hyphen or contain two consecutive hyphens.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Engine`

The name of the cache engine to be used for this cache cluster, such as `memcached` or `redis`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`EngineVersion`

The version of the cache engine to be used for this cluster.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`NotificationTopicArn`

The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent.

Required: No

Type: String

Update requires: No interruption (p. 120)

`NumCacheNodes`

The number of cache nodes that the cache cluster should have.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120). However, if the `PreferredAvailabilityZone` and `PreferredAvailabilityZones` properties were not previously specified and you don't specify any new values, an update requires replacement (p. 121).

`Port`

The port number on which each of the cache nodes will accept connections.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`PreferredAvailabilityZone`

The Amazon EC2 Availability Zone in which the cache cluster is created.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PreferredAvailabilityZones`

For Memcached cache clusters, the list of Availability Zones in which cache nodes are created. The number of Availability Zones listed must equal the number of cache nodes. For example, if you want to create three nodes in two different Availability Zones, you can specify `["us-east-1a", "us-east-1a", "us-east-1b"]`, which would create two nodes in us-east-1a and one node in us-east-1b.

If you specify a subnet group and you're creating your cache cluster in a VPC, you must specify Availability Zones that are associated with the subnets in the subnet group that you've chosen.

If you want all the nodes in the same Availability Zone, use the `PreferredAvailabilityZone` property or repeat the Availability Zone multiple times in the list.

Required: No

Type: List of String values

If you specify an Availability Zone that was previously specified in the template, such as in the `PreferredAvailabilityZone` property, the update requires some interruptions (p. 121). Also, if the `PreferredAvailabilityZones` property was already specified and you're updating its values (regardless of whether you specify the same Availability Zones), the update requires some interruptions (p. 121).

All other updates require replacement (p. 121).

`PreferredMaintenanceWindow`

The weekly time range (in UTC) during which system maintenance can occur.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SnapshotArns`

The ARN of the snapshot file that you want to use to seed a new Redis cache cluster. If you manage a Redis instance outside of Amazon ElastiCache, you can create a new cache cluster in ElastiCache by using a snapshot file that is stored in an Amazon S3 bucket.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`SnapshotName`

The name of a snapshot from which to restore data into a new Redis cache cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SnapshotRetentionLimit`

For Redis cache clusters, the number of days for which ElastiCache retains automatic snapshots before deleting them. For example, if you set the value to `5`, a snapshot that was taken today will be retained for 5 days before being deleted.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`SnapshotWindow`

For Redis cache clusters, the daily time range (in UTC) during which ElastiCache will begin taking a daily snapshot of your node group. For example, you can specify `05:00-09:00`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Tags`

An arbitrary set of tags (key–value pairs) for this cache cluster.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

`VpcSecurityGroupIds`

A list of VPC security group IDs. If your cache cluster isn't in a VPC, specify the `CacheSecurityGroupNames` property instead.

> **Note**
> You must use the `AWS::EC2::SecurityGroup` resource instead of the `AWS::ElastiCache::SecurityGroup` resource in order to specify an ElastiCache security group that is in a VPC. In addition, if you use the default VPC for your AWS account, you must use the `Fn::GetAtt` function and the `GroupId` attribute to retrieve security group IDs (instead of the `Ref` function). To see a sample template, see the Template Snippet section.

Required: Conditional: If your cache cluster is in a VPC, you must specify this property.

Type: List of String values

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`ConfigurationEndpoint.Address`

The DNS address of the configuration endpoint for the Memcached cache cluster.

`ConfigurationEndpoint.Port`

The port number of the configuration endpoint for the Memcached cache cluster.

`RedisEndpoint.Address`

The DNS address of the configuration endpoint for the Redis cache cluster.

`RedisEndpoint.Port`

The port number of the configuration endpoint for the Redis cache cluster.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Template Snippets

Cluster in a Default VPC

The following snippet describes an ElastiCache cluster in a security group that is in a default VPC. Usually, a security group in a VPC requires the VPC ID to be specified. In this case, no VPC ID is needed because the security group uses the default VPC. If you want to specify a VPC for the security group, specify its `VpcId` property.

For the cache cluster, the `VpcSecurityGroupIds` property is used to associate the cluster with the security group. Because the `VpcSecurityGroupIds` property requires security group IDs (not security group names), the template snippet uses the `Fn::GetAtt` function instead of a `Ref` function on the `ElasticacheSecurityGroup` resource. The `Ref` function will return the security group name. If you specify a VPC ID for the security group, `Ref` returns the security group ID.

Note that `InstanceSecurityGroup` refers to the logical name of a security group that is not actually defined in this snippet. To learn more about the `SourceSecurityGroupName` property, see AWS::EC2::SecurityGroupIngress (p. 1238).

JSON

```
"ElasticacheSecurityGroup": {
  "Type": "AWS::EC2::SecurityGroup",
  "Properties": {
    "GroupDescription": "Elasticache Security Group",
    "SecurityGroupIngress": [ {
      "IpProtocol": "tcp",
      "FromPort": "11211",
      "ToPort": "11211",
      "SourceSecurityGroupName": {"Ref": "InstanceSecurityGroup"}
    } ]
  }
},
"ElasticacheCluster": {
  "Type": "AWS::ElastiCache::CacheCluster",
  "Properties": {
    "AutoMinorVersionUpgrade": "true",
    "Engine": "memcached",
    "CacheNodeType": "cache.t2.micro",
    "NumCacheNodes": "1",
    "VpcSecurityGroupIds": [{"Fn::GetAtt": [ "ElasticacheSecurityGroup", "GroupId"]}]
  }
}
```

YAML

```
ElasticacheSecurityGroup:
  Type: AWS::EC2::SecurityGroup
  Properties:
    GroupDescription: "Elasticache Security Group"
    SecurityGroupIngress:
      -
        IpProtocol: "tcp"
        FromPort: "11211"
        ToPort: "11211"
        SourceSecurityGroupName:
          Ref: "InstanceSecurityGroup"
ElasticacheCluster:
  Type: AWS::ElastiCache::CacheCluster
  Properties:
    AutoMinorVersionUpgrade: "true"
```

```
    Engine: "memcached"
    CacheNodeType: "cache.t2.micro"
    NumCacheNodes: "1"
    VpcSecurityGroupIds:
      -
        Fn::GetAtt:
          - "ElasticacheSecurityGroup"
          - "GroupId"
```

Memcached Nodes in Multiple Availability Zones

The following example launches a cache cluster with three nodes, where two nodes are created in us-west-2a and one is created in us-west-2b.

JSON

```
"myCacheCluster" : {
  "Type": "AWS::ElastiCache::CacheCluster",
  "Properties" : {
    "AZMode" : "cross-az",
    "CacheNodeType" : "cache.m3.medium",
    "Engine" : "memcached",
    "NumCacheNodes" : "3",
    "PreferredAvailabilityZones" : [ "us-west-2a", "us-west-2a", "us-west-2b" ]
  }
}
```

YAML

```
myCacheCluster:
  Type: AWS::ElastiCache::CacheCluster
  Properties:
    AZMode: "cross-az"
    CacheNodeType: "cache.m3.medium"
    Engine: "memcached"
    NumCacheNodes: "3"
    PreferredAvailabilityZones:
      - "us-west-2a"
      - "us-west-2a"
      - "us-west-2b"
```

AWS::ElastiCache::ParameterGroup

The AWS::ElastiCache::ParameterGroup type creates a new cache parameter group. Cache parameter groups control the parameters for a cache cluster.

Topics

- Syntax (p. 1394)
- Properties (p. 1394)
- Return Values (p. 1395)
- Example (p. 1395)
- See Also (p. 1395)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type": "AWS::ElastiCache::ParameterGroup",
   "Properties": {
      "CacheParameterGroupFamily" : String,
      "Description" : String,
      "Properties" : { String:String, ... }
   }
}
```

YAML

```
Type: AWS::ElastiCache::ParameterGroup
Properties:
  CacheParameterGroupFamily: String
  Description: String
  Properties:
    String: String
```

Properties

`CacheParameterGroupFamily`

The name of the cache parameter group family that the cache parameter group can be used with.

Required: Yes

Type: String

Update requires: Updates are not supported.

`Description`

The description for the Cache Parameter Group.

Required: Yes

Type: String

Update requires: Updates are not supported.

`Properties`

A comma-delimited list of parameter name/value pairs. For more information, go to ModifyCacheParameterGroup in the *Amazon ElastiCache API Reference Guide*.

Example:

```
"Properties" : {
   "cas_disabled" : "1",
   "chunk_size_growth_factor" : "1.02"
}
```

Required: No

Type: Mapping of key-value pairs

Update requires: Updates are not supported.

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
"MyParameterGroup": {
   "Type": "AWS::ElastiCache::ParameterGroup",
   "Properties": {
      "Description": "MyNewParameterGroup",
      "CacheParameterGroupFamily": "memcached1.4",
      "Properties" : {
         "cas_disabled" : "1",
         "chunk_size_growth_factor" : "1.02"
      }
   }
}
```

YAML

```
MyParameterGroup:
  Type: AWS::ElastiCache::ParameterGroup
  Properties:
    Description: "MyNewParameterGroup"
    CacheParameterGroupFamily: "memcached1.4"
    Properties:
      cas_disabled: "1"
      chunk_size_growth_factor: "1.02"
```

AWS::ElastiCache::ReplicationGroup

The `AWS::ElastiCache::ReplicationGroup` resource creates an Amazon ElastiCache Redis replication group. A *replication group* is a collection of cache clusters, where one of the clusters is a primary read-write cluster and the others are read-only replicas.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElastiCache::ReplicationGroup",
  "Properties" : {
    "AtRestEncryptionEnabled" : Boolean,
    "AuthToken" : String,
    "AutomaticFailoverEnabled" : Boolean,
    "AutoMinorVersionUpgrade" : Boolean,
    "CacheNodeType" : String,
    "CacheParameterGroupName" : String,
    "CacheSecurityGroupNames" : [ String, ... ],
    "CacheSubnetGroupName" : String,
    "Engine" : String,
    "EngineVersion" : String,
    "NodeGroupConfiguration" : [ NodeGroupConfiguration (p. 1406) ],
    "NotificationTopicArn" : String,
    "NumCacheClusters" : Integer,
    "NumNodeGroups" : Integer,
    "Port" : Integer,
    "PreferredCacheClusterAZs" : [ String, ... ],
    "PreferredMaintenanceWindow" : String,
    "PrimaryClusterId" : String,
    "ReplicasPerNodeGroup" : Integer,
    "ReplicationGroupDescription" : String,
    "ReplicationGroupId" : String,
    "SecurityGroupIds" : [ String, ... ],
    "SnapshotArns" : [ String, ... ],
    "SnapshotName" : String,
    "SnapshotRetentionLimit" : Integer,
    "SnapshottingClusterId" : String,
    "SnapshotWindow" : String,
    "Tags" : Resource Tag, ...,
    "TransitEncryptionEnabled" : Boolean
  }
}
```

YAML

```
Type: AWS::ElastiCache::ReplicationGroup
Properties:
  AtRestEncryptionEnabled: Boolean
  AuthToken: String
  AutomaticFailoverEnabled: Boolean
  AutoMinorVersionUpgrade: Boolean
  CacheNodeType: String
  CacheParameterGroupName: String
  CacheSecurityGroupNames:
    - String
  CacheSubnetGroupName: String
  Engine: String
  EngineVersion: String
  NodeGroupConfiguration:
    - NodeGroupConfiguration (p. 1406)
  NotificationTopicArn: String
  NumCacheClusters: Integer
  NumNodeGroups: Integer
  Port: Integer
  PreferredCacheClusterAZs:
    - String
  PreferredMaintenanceWindow: String
  PrimaryClusterId: String
  ReplicasPerNodeGroup: Integer
  ReplicationGroupDescription: String
```

```
  ReplicationGroupId: String
  SecurityGroupIds:
    - String
  SnapshotArns:
    - String
  SnapshotName: String
  SnapshotRetentionLimit: Integer
  SnapshottingClusterId: String
  SnapshotWindow: String
  Tags:
    - Resource Tag
  TransitEncryptionEnabled: Boolean
```

Properties

For more information about each property and valid values, see CreateReplicationGroup in the *Amazon ElastiCache API Reference*.

`AtRestEncryptionEnabled`

Indicates whether to enable encryption at rest. The default value is `false`. For more information about how you can use this property, see CreateReplicationGroup in the *Amazon ElastiCache API Reference*.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`AuthToken`

The password that's used to access a password-protected server. For constraints, see CreateReplicationGroup in the *Amazon ElastiCache API Reference*.

`AuthToken` can be specified only on replication groups where `TransitEncryptionEnabled` is `true`.

> **Important**
> For HIPAA compliance, you must specify `TransitEncryptionEnabled` as `true`, an `AuthToken`, and a `CacheSubnetGroupName`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`AutomaticFailoverEnabled`

Indicates whether Multi-AZ is enabled. When Multi-AZ is enabled, a read-only replica is automatically promoted to a read-write primary cluster if the existing primary cluster fails. If you specify `true`, you must specify a value greater than `1` for the `NumCacheClusters` property. By default, AWS CloudFormation sets the value to `true`.

For Redis (clustered mode enabled) replication groups, you must enable automatic failover.

For information about Multi-AZ constraints, see Replication with Multi-AZ and Automatic Failover (Redis) in the *Amazon ElastiCache User Guide*.

> **Note**
> You cannot enable automatic failover for Redis versions earlier than 2.8.6 or for T1 cache node types. Automatic failover is supported on T2 node types only if you are running Redis version 3.2.4 or later with cluster mode enabled.

Important
If you specify the `PrimaryClusterId`, you can use only the following additional parameters:

- `AutomaticFailoverEnabled`
- `NodeGroupConfiguration`
- `NumCacheClusters`
- `NumNodeGroups`
- `PreferredCacheClusterAZs`
- `ReplicationGroupDescription`

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`AutoMinorVersionUpgrade`

Currently, this property isn't used by ElastiCache.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`CacheNodeType`

The compute and memory capacity of nodes in the node group. For valid values, see CreateReplicationGroup in the *Amazon ElastiCache API Reference Guide*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`CacheParameterGroupName`

The name of the parameter group to associate with this replication group. For valid and default values, see CreateReplicationGroup in the *Amazon ElastiCache API Reference Guide*.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`CacheSecurityGroupNames`

A list of cache security group names to associate with this replication group.

Important
If you specify the `CacheSecurityGroupNames` property, don't also specify the `SecurityGroupIds` property.
The `SecurityGroupIds` property is only for Amazon Virtual Private Cloud (Amazon VPC) security groups. If you specify an Amazon VPC security group, the deployment fails.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`CacheSubnetGroupName`

The name of a cache subnet group to use for this replication group.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Engine`

The name of the cache engine to use for the cache clusters in this replication group. Currently, you can specify only `redis`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`EngineVersion`

The version number of the cache engine to use for the cache clusters in this replication group.

Required: No

Type: String

Update requires: No interruption (p. 120)

`NodeGroupConfiguration`

Configuration options for the node group (shard).

Important
If you specify the `PrimaryClusterId`, you can use only the following additional parameters:

- `AutomaticFailoverEnabled`
- `NodeGroupConfiguration`
- `NumCacheClusters`
- `NumNodeGroups`
- `PreferredCacheClusterAZs`
- `ReplicationGroupDescription`

Required: No

Type: List of Amazon ElastiCache ReplicationGroup NodeGroupConfiguration (p. 1406)

Update requires: Some interruptions (p. 121) Update requires no interruption if the resource contains an `UseOnlineResharding` update policy set to `true`. Update requires replacement if the resource does not contain an `UseOnlineResharding` update policy, or the policy is set to `false`. For more information, see UseOnlineResharding Policy (p. 2286).

`NotificationTopicArn`

The Amazon Resource Name (ARN) of the Amazon Simple Notification Service topic to which notifications are sent.

Required: No

Type: String

Update requires: No interruption (p. 120)

`NumCacheClusters`

The number of cache clusters for this replication group. If automatic failover is enabled, you must specify a value greater than `1`. For valid values, see CreateReplicationGroup in the *Amazon ElastiCache API Reference Guide*.

If you specify more than one node group (shard), this property is ignored. Use the `ReplicasPerNodeGroup` property instead.

> **Important**
> If you specify the `PrimaryClusterId`, you can use only the following additional parameters:
> - `AutomaticFailoverEnabled`
> - `NodeGroupConfiguration`
> - `NumCacheClusters`
> - `NumNodeGroups`
> - `PreferredCacheClusterAZs`
> - `ReplicationGroupDescription`

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`NumNodeGroups`

The number of node groups (shards) for this Redis (clustered mode enabled) replication group. For Redis (clustered mode disabled), either omit this property or set it to 1.

> **Important**
> If you specify the `PrimaryClusterId`, you can use only the following additional parameters:
> - `AutomaticFailoverEnabled`
> - `NodeGroupConfiguration`
> - `NumCacheClusters`
> - `NumNodeGroups`
> - `PreferredCacheClusterAZs`
> - `ReplicationGroupDescription`

Required: No

Type: Integer

Update requires: Some interruptions (p. 121) Update requires no interruption if the resource contains an `UseOnlineResharding` update policy set to `true`. Update requires replacement if the resource does not contain an `UseOnlineResharding` update policy, or the policy is set to `false`. For more information, see UseOnlineResharding Policy (p. 2286).

`Port`

The port number on which each member of the replication group accepts connections.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`PreferredCacheClusterAZs`

A list of Availability Zones in which the cache clusters in this replication group are created.

> **Important**
> If you specify the `PrimaryClusterId`, you can use only the following additional parameters:
> - `AutomaticFailoverEnabled`
> - `NodeGroupConfiguration`
> - `NumCacheClusters`
> - `NumNodeGroups`
> - `PreferredCacheClusterAZs`
> - `ReplicationGroupDescription`

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`PreferredMaintenanceWindow`

The weekly time range during which system maintenance can occur. Use the following format to specify a time range: `ddd:hh24:mi-ddd:hh24:mi` (24H Clock UTC). For example, you can specify `sun:22:00-sun:23:30` for Sunday from 10 PM to 11:30 PM.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PrimaryClusterId`

The cache cluster that ElastiCache uses as the primary cluster for the replication group. The cache cluster must have a status of `available`.

> **Important**
> If you specify the `PrimaryClusterId`, you can use only the following additional parameters:
> - `AutomaticFailoverEnabled`
> - `NodeGroupConfiguration`
> - `NumCacheClusters`
> - `NumNodeGroups`
> - `PreferredCacheClusterAZs`
> - `ReplicationGroupDescription`

Required: Conditional. This property is optional if you specify the `NumCacheClusters`, `NumNodeGroups`, or `ReplicasPerNodeGroup` properties.

Type: String

Update requires: No interruption (p. 120)

`ReplicasPerNodeGroup`

The number of replica nodes in each node group (shard). For valid values, see CreateReplicationGroup in the *Amazon ElastiCache API Reference Guide*.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`ReplicationGroupDescription`

A description of the replication group.

> **Important**
> If you specify the `PrimaryClusterId`, you can use only the following additional parameters:
> - `AutomaticFailoverEnabled`
> - `NodeGroupConfiguration`
> - `NumCacheClusters`
> - `NumNodeGroups`
> - `PreferredCacheClusterAZs`
> - `ReplicationGroupDescription`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ReplicationGroupId`

An ID for the replication group. If you don't specify an ID, AWS CloudFormation generates a unique physical ID. For more information, see Name Type (p. 2256).

Required: No

Type: String

Update requires: Replacement (p. 121)

`SecurityGroupIds`

A list of Amazon Virtual Private Cloud (Amazon VPC) security groups to associate with this replication group.

> **Important**
> If you specify the `SecurityGroupIds` property, don't also specify the `CacheSecurityGroupNames` property.
> The `CacheSecurityGroupNames` property is only for EC2-Classic security groups. If you specify an EC2-Classic security group, the deployment fails.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SnapshotArns`

A single-element string list that specifies an ARN of a Redis `.rdb` snapshot file that is stored in Amazon Simple Storage Service (Amazon S3). The snapshot file populates the node group. The Amazon S3 object name in the ARN cannot contain commas. For example, you can specify `arn:aws:s3:::my_bucket/snapshot1.rdb`.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`SnapshotName`

The name of a snapshot from which to restore data into the replication group.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SnapshotRetentionLimit`

The number of days that ElastiCache retains automatic snapshots before deleting them.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`SnapshottingClusterId`

The ID of the cache cluster that ElastiCache uses as the daily snapshot source for the replication group.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SnapshotWindow`

The time range (in UTC) when ElastiCache takes a daily snapshot of the node group that you specified in the `SnapshottingClusterId` property. For example, you can specify `05:00-09:00`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Tags`

An arbitrary set of tags (key–value pairs) for this replication group.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`TransitEncryptionEnabled`

Indicates whether to enable in-transit encryption. The default value is `false`. For more information about how you can use this property, see CreateReplicationGroup in the *Amazon ElastiCache API Reference*.

If you enable `TransitEncryptionEnabled`, then you must also specify `CacheSubnetGroupName`.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

In the following example, the `Ref` function returns the name of the `myReplicationGroup` replication group, such as `abc12xmy3d1w3hv6`.

```
{ "Ref": "myReplicationGroup" }
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`ConfigurationEndPoint.Address`

The DNS hostname of the cache node.

> **Note**
> Redis (cluster mode disabled) replication groups don't have this attribute. Therefore, `Fn::GetAtt` returns a value for this attribute only if the replication group is clustered. Otherwise, `Fn::GetAtt` fails.

`ConfigurationEndPoint.Port`

The port number that the cache engine is listening on.

`PrimaryEndPoint.Address`

The DNS address of the primary read-write cache node.

`PrimaryEndPoint.Port`

The number of the port that the primary read-write cache engine is listening on.

`ReadEndPoint.Addresses`

A string with a list of endpoints for the read-only replicas. The order of the addresses maps to the order of the ports from the `ReadEndPoint.Ports` attribute.

`ReadEndPoint.Ports`

A string with a list of ports for the read-only replicas. The order of the ports maps to the order of the addresses from the `ReadEndPoint.Addresses` attribute.

`ReadEndPoint.Addresses.List`

A list of endpoints for the read-only replicas. The order of the addresses maps to the order of the ports from the `ReadEndPoint.Ports.List` attribute.

`ReadEndPoint.Ports.List`

A list of ports for the read-only replicas. The order of the ports maps to the order of the addresses from the `ReadEndPoint.Addresses.List` attribute.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Declare a Replication Group with Two Nodes

The following example declares a replication group with two nodes and automatic failover enabled.

JSON

```
"myReplicationGroup" : {
  "Type": "AWS::ElastiCache::ReplicationGroup",
  "Properties": {
    "ReplicationGroupDescription" : "my description",
    "NumCacheClusters" : "2",
    "Engine" : "redis",
    "CacheNodeType" : "cache.m3.medium",
    "AutoMinorVersionUpgrade" : "true",
    "AutomaticFailoverEnabled" : "true",
    "CacheSubnetGroupName" : "subnetgroup",
    "EngineVersion" : "2.8.6",
    "PreferredMaintenanceWindow" : "wed:09:25-wed:22:30",
    "SnapshotRetentionLimit" : "4",
    "SnapshotWindow" : "03:30-05:30"
  }
}
```

YAML

```
myReplicationGroup:
  Type: AWS::ElastiCache::ReplicationGroup
  Properties:
    ReplicationGroupDescription: "my description"
    NumCacheClusters: "2"
    Engine: "redis"
    CacheNodeType: "cache.m3.medium"
    AutoMinorVersionUpgrade: "true"
    AutomaticFailoverEnabled: "true"
    CacheSubnetGroupName: "subnetgroup"
    EngineVersion: "2.8.6"
    PreferredMaintenanceWindow: "wed:09:25-wed:22:30"
    SnapshotRetentionLimit: "4"
    SnapshotWindow: "03:30-05:30"
```

Declare a Replication Group with Two Node Groups

The following example declares a replication group with two nodes groups (shards) with three replicas in each group.

JSON

```
"BasicReplicationGroup" : {
  "Type" : "AWS::ElastiCache::ReplicationGroup",
  "Properties" : {
    "AutomaticFailoverEnabled" : true,
    "AutoMinorVersionUpgrade" : true,
    "CacheNodeType" : "cache.r3.large",
    "CacheSubnetGroupName" : { "Ref" : "CacheSubnetGroup" },
    "Engine" : "redis",
    "EngineVersion" : "3.2",
    "NumNodeGroups" : "2",
    "ReplicasPerNodeGroup" : "3",
    "Port" : 6379,
```

```
    "PreferredMaintenanceWindow" : "sun:05:00-sun:09:00",
    "ReplicationGroupDescription" : "A sample replication group",
    "SecurityGroupIds" : [
      { "Ref" : "ReplicationGroupSG" }
    ],
    "SnapshotRetentionLimit" : 5,
    "SnapshotWindow" : "10:00-12:00"
  }
}
```

YAML

```
BasicReplicationGroup:
  Type: AWS::ElastiCache::ReplicationGroup
  Properties:
    AutomaticFailoverEnabled: true
    AutoMinorVersionUpgrade: true
    CacheNodeType: cache.r3.large
    CacheSubnetGroupName:
      Ref: CacheSubnetGroup
    Engine: redis
    EngineVersion: '3.2'
    NumNodeGroups: '2'
    ReplicasPerNodeGroup: '3'
    Port: 6379
    PreferredMaintenanceWindow: sun:05:00-sun:09:00
    ReplicationGroupDescription: A sample replication group
    SecurityGroupIds:
      - Ref: ReplicationGroupSG
    SnapshotRetentionLimit: 5
    SnapshotWindow: 10:00-12:00
```

Amazon ElastiCache ReplicationGroup NodeGroupConfiguration

`NodeGroupConfiguration` is a property of the AWS::ElastiCache::ReplicationGroup (p. 1395) resource that configures an Amazon ElastiCache (ElastiCache) Redis cluster node group.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "NodeGroupId" : String,
  "PrimaryAvailabilityZone" : String,
  "ReplicaAvailabilityZones" : [ String, ... ],
  "ReplicaCount" : Integer,
  "Slots" : String
}
```

YAML

```
NodeGroupId: String
PrimaryAvailabilityZone: String
```

```
ReplicaAvailabilityZones:
  - String
ReplicaCount: Integer
Slots: String
```

Properties

`NodeGroupId`

Either the ElastiCache for Redis supplied 4-digit id or a user supplied id for the node group these configuration values apply to.

Length Constraints: Minimum length of 1. Maximum length of 4.

Pattern: `\d+`

Required: No

Type: String

Update requires: Some interruptions (p. 121). Update requires no interruption if the resource contains an `UseOnlineResharding` update policy set to `true`. Update requires replacement if the resource does not contain an `UseOnlineResharding` update policy, or the policy is set to `false`. For more information, see UseOnlineResharding Policy (p. 2286).

`PrimaryAvailabilityZone`

The Availability Zone where ElastiCache launches the node group's primary node.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ReplicaAvailabilityZones`

A list of Availability Zones where ElastiCache launches the read replicas. The number of Availability Zones must match the value of the `ReplicaCount` property or, if you don't specify the `ReplicaCount` property, the replication group's `ReplicasPerNodeGroup` property.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`ReplicaCount`

The number of read replica nodes in the node group.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`Slots`

A string of comma-separated values where the first set of values are the slot numbers (zero based), and the second set of values are the keyspaces for each slot. The following example specifies three slots (numbered 0, 1, and 2): `0,1,2,0-4999,5000-9999,10000-16,383`.

If you don't specify a value, ElastiCache allocates keys equally among each slot.

When you use an `UseOnlineResharding` update policy to update the number of node groups without interruption, ElastiCache evenly distributes the keyspaces between the specified number of slots. This cannot be updated later. Therefore, after updating the number of node groups in this way, you should remove the value specified for the `Slots` property of each `NodeGroupConfiguration` from the stack template, as it no longer reflects the actual values in each node group. For more information, see UseOnlineResharding Policy (p. 2286).

Required: No

Type: String

Update requires: Replacement (p. 121)

AWS::ElastiCache::SecurityGroup

The `AWS::ElastiCache::SecurityGroup` resource creates a cache security group. For more information about cache security groups, go to Cache Security Groups in the *Amazon ElastiCache User Guide* or go to CreateCacheSecurityGroup in the *Amazon ElastiCache API Reference Guide*.

To create an ElastiCache cluster in a VPC, use the AWS::EC2::SecurityGroup (p. 1225) resource. For more information, see the `VpcSecurityGroupIds` property in the AWS::ElastiCache::CacheCluster (p. 1386) resource.

Topics

- Syntax (p. 1408)
- Properties (p. 1408)
- Return Values (p. 1409)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElastiCache::SecurityGroup",
  "Properties" :
  {
    "Description" : String
  }
}
```

YAML

```
Type: AWS::ElastiCache::SecurityGroup
Properties:
  Description: String
```

Properties

`Description`

A description for the cache security group.

Type: String

Required: No

Update requires: Updates are not supported.

Return Values

Ref

When you specify the `AWS::ElastiCache::SecurityGroup` resource as an argument to the `Ref` function, AWS CloudFormation returns the `CacheSecurityGroupName` property of the cache security group.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::ElastiCache::SecurityGroupIngress

The AWS::ElastiCache::SecurityGroupIngress type authorizes ingress to a cache security group from hosts in specified Amazon EC2 security groups. For more information about ElastiCache security group ingress, go to AuthorizeCacheSecurityGroupIngress in the *Amazon ElastiCache API Reference Guide*.

Topics

- Syntax (p. 1409)
- Properties (p. 1409)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElastiCache::SecurityGroupIngress",
  "Properties" :
  {
    "CacheSecurityGroupName" : String,
    "EC2SecurityGroupName" : String,
    "EC2SecurityGroupOwnerId" : String
  }
}
```

YAML

```
Type: AWS::ElastiCache::SecurityGroupIngress
Properties:
  CacheSecurityGroupName: String
  EC2SecurityGroupName: String
  EC2SecurityGroupOwnerId: String
```

Properties

`CacheSecurityGroupName`

The name of the Cache Security Group to authorize.

Type: String

Required: Yes

Update requires: Updates are not supported.

`EC2SecurityGroupName`

Name of the EC2 Security Group to include in the authorization.

Type: String

Required: Yes

Update requires: Updates are not supported.

`EC2SecurityGroupOwnerId`

Specifies the AWS Account ID of the owner of the EC2 security group specified in the EC2SecurityGroupName property. The AWS access key ID is not an acceptable value.

Type: String

Required: No

Update requires: Updates are not supported.

AWS::ElastiCache::SubnetGroup

Creates a cache subnet group. For more information about cache subnet groups, go to Cache Subnet Groups in the *Amazon ElastiCache User Guide* or go to CreateCacheSubnetGroup in the *Amazon ElastiCache API Reference Guide*.

Topics

- Syntax (p. 1410)
- Properties (p. 1411)
- Return Value (p. 1411)
- Example (p. 1411)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElastiCache::SubnetGroup",
  "Properties" : {
    "CacheSubnetGroupName" : String,
    "Description (p. 1411)" : String,
    "SubnetIds (p. 1411)" : [ String, ... ]
  }
}
```

YAML

```
Type: AWS::ElastiCache::SubnetGroup
Properties:
  CacheSubnetGroupName: String
  Description (p. 1411): String
  SubnetIds (p. 1411):
```

```
    - String
```

Properties

`CacheSubnetGroupName`

A name for the cache subnet group. If you don't specify a name, AWS CloudFormation generates a unique physical ID. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Description`

The description for the cache subnet group.

Type: String

Required: Yes

Update requires: No interruption (p. 120)

`SubnetIds`

The Amazon EC2 subnet IDs for the cache subnet group.

Type: String list

Required: Yes

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
"SubnetGroup" : {
    "Type" : "AWS::ElastiCache::SubnetGroup",
    "Properties" : {
        "Description" : "Cache Subnet Group",
        "SubnetIds" : [ { "Ref" : "Subnet1" }, { "Ref" : "Subnet2" } ]
    }
}
```

YAML

```
SubnetGroup:
  Type: AWS::ElastiCache::SubnetGroup
  Properties:
    Description: "Cache Subnet Group"
    SubnetIds:
      - Ref: "Subnet1"
      - Ref: "Subnet2"
```

Amazon Elasticsearch Service Resource Types Reference

This section contains reference information for all Amazon Elasticsearch Service resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::Elasticsearch::data-type-name
```

Topics

- AWS::Elasticsearch::Domain (p. 1412)

AWS::Elasticsearch::Domain

The `AWS::Elasticsearch::Domain` resource creates an Amazon Elasticsearch Service (Amazon ES) domain that encapsulates the Amazon ES engine instances. For more information, see CreateElasticsearchDomain in the *Amazon Elasticsearch Service Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Elasticsearch::Domain",
  "Properties" : {
    "AccessPolicies" : JSON object,
    "AdvancedOptions" : { String:String, ... },
    "DomainName" : String,
    "EBSOptions" : EBSOptions (p. 1420),
    "ElasticsearchClusterConfig" : ElasticsearchClusterConfig (p. 1421),
    "ElasticsearchVersion" : String,
    "EncryptionAtRestOptions" : EncryptionAtRestOptions (p. 1422),
    "SnapshotOptions" : SnapshotOptions (p. 1423),
    "Tags" : [ Resource Tag, ... ],
    "VPCOptions" : VPCOptions (p. 1424)
  }
}
```

YAML

```
Type: AWS::Elasticsearch::Domain
```

```
Properties:
  AccessPolicies: JSON object
  AdvancedOptions:
    String: String
  DomainName: String
  EBSOptions:
    EBSOptions (p. 1420)
  ElasticsearchClusterConfig:
    ElasticsearchClusterConfig (p. 1421)
  ElasticsearchVersion: String
  EncryptionAtRestOptions:
    EncryptionAtRestOptions (p. 1422)
  SnapshotOptions:
    SnapshotOptions (p. 1423)
  Tags:
    - Resource Tag
  VPCOptions:
    VPCOptions (p. 1424)
```

Properties

`AccessPolicies`

An AWS Identity and Access Management (IAM) policy document that specifies who can access the Amazon ES domain and their permissions. For more information, see Configuring Access Policies in the *Amazon Elasticsearch Service Developer Guide*.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`AdvancedOptions`

Additional options to specify for the Amazon ES domain. For more information, see Configuring Advanced Options in the *Amazon Elasticsearch Service Developer Guide*.

Required: No

Type: A JSON object that consists of a string key-value pair, such as:

```
{
  "rest.action.multi.allow_explicit_index": "true"
}
```

Update requires: Replacement (p. 121)

`DomainName`

A name for the Amazon ES domain. For valid values, see the DomainName data type in the *Amazon Elasticsearch Service Developer Guide*.

If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the domain name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`EBSOptions`

The configurations of Amazon Elastic Block Store (Amazon EBS) volumes that are attached to data nodes in the Amazon ES domain. For more information, see Configuring EBS-based Storage in the *Amazon Elasticsearch Service Developer Guide*.

Required: No

Type: EBSOptions (p. 1420)

Update requires: No interruption (p. 120)

`ElasticsearchClusterConfig`

The cluster configuration for the Amazon ES domain. You can specify options such as the instance type and the number of instances. For more information, see Configuring Amazon ES Domains in the *Amazon Elasticsearch Service Developer Guide*.

Required: No

Type: ElasticsearchClusterConfig (p. 1421)

Update requires: No interruption (p. 120)

`ElasticsearchVersion`

The version of Elasticsearch to use, such as `2.3`. For information about the versions that Amazon ES supports, see the `Elasticsearch-Version` parameter for the CreateElasticsearchDomain action in the *Amazon Elasticsearch Service Developer Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`EncryptionAtRestOptions`

Whether the domain should encrypt data at rest, and if so, the AWS Key Management Service (KMS) key to use. Can only be used to create a new domain, not update an existing one.

Required: No

Type: EncryptionAtRestOptions (p. 1422)

Update requires: Replacement (p. 120)

`SnapshotOptions`

The automated snapshot configuration for the Amazon ES domain indices.

Required: No

Type: SnapshotOptions (p. 1423)

Update requires: No interruption (p. 120)

`Tags`

An arbitrary set of tags (key–value pairs) to associate with the Amazon ES domain.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`VPCOptions`

The virtual private cloud (VPC) configuration for the Amazon ES domain. For more information, see VPC Support for Amazon Elasticsearch Service Domains in the *Amazon Elasticsearch Service Developer Guide*.

Required: No

Type: VPCOptions (p. 1424)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name, such as `mystack-elasticsea-abc1d2efg3h4`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`DomainArn`

The Amazon Resource Name (ARN) of the domain, such as `arn:aws:es:us-west-2:123456789012:domain/mystack-elasti-1ab2cdefghij`.

`DomainEndpoint`

The domain-specific endpoint that's used to submit index, search, and data upload requests to an Amazon ES domain, such as `search-mystack-elasti-1ab2cdefghij-ab1c2deckoyb3hofw7wpqa3cm.us-west-2.es.amazonaws.com`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

The following examples create an Amazon ES domain that contains two data nodes and three master nodes. Automated snapshots of the indices are taken daily between midnight and 1:00 AM (UTC). The access policy permits the IAM user `es-user` to take all Amazon ES actions on the domain, such as `es:UpdateElasticsearchDomainConfig`.

JSON

```
"ElasticsearchDomain": {
  "Type": "AWS::Elasticsearch::Domain",
  "Properties": {
    "DomainName": "test",
    "ElasticsearchClusterConfig": {
```

```
      "DedicatedMasterEnabled": "true",
      "InstanceCount": "2",
      "ZoneAwarenessEnabled": "true",
      "InstanceType": "m3.medium.elasticsearch",
      "DedicatedMasterType": "m3.medium.elasticsearch",
      "DedicatedMasterCount": "3"
    },
    "EBSOptions": {
      "EBSEnabled": true,

      }]
    },
    "AdvancedOptions": {
      "rest.action.multi.allow_explicit_index": "true"
    }
  }
}
```

YAML

```
ElasticsearchDomain:
  Type: AWS::Elasticsearch::Domain
  Properties:
    DomainName: "test"
    ElasticsearchClusterConfig:
      DedicatedMasterEnabled: "true"
      InstanceCount: "2"
      ZoneAwarenessEnabled: "true"
      InstanceType: "m3.medium.elasticsearch"
      DedicatedMasterType: "m3.medium.elasticsearch"
      DedicatedMasterCount: "3"
    EBSOptions:
      EBSEnabled: true
      Iops: 0
      VolumeSize: 20
      VolumeType: "gp2"
    SnapshotOptions:
      AutomatedSnapshotStartHour: "0"
    AccessPolicies:
      Version: "2012-10-17"
      Statement:
        -
          Effect: "Allow"
          Principal:
            AWS: "arn:aws:iam::123456789012:user/es-user"
          Action: "es:*"
          Resource: "arn:aws:es:us-east-1:846973539254:domain/test/*"
    AdvancedOptions:
      rest.action.multi.allow_explicit_index: "true"
```

The following example creates a domain with VPC options.

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Description": "ElasticsearchDomain resource",
  "Parameters": {
    "DomainName" : {
      "Description" : "User defined Elasticsearch Domain name",
      "Type" : "String"
    },

```

Amazon Elasticsearch Service Domain EBSOptions

`EBSOptions` is a property of the AWS::Elasticsearch::Domain (p. 1412) resource that configures the Amazon Elastic Block Store (Amazon EBS) volumes that are attached to data nodes in the Amazon Elasticsearch Service (Amazon ES) domain.

Syntax

JSON

```
{
  "EBSEnabled" : Boolean,
  "Iops" : Integer,
  "VolumeSize" : Integer,
  "VolumeType" : String
}
```

YAML

```
EBSEnabled: Boolean
Iops: Integer
VolumeSize: Integer
VolumeType: String
```

Properties

`EBSEnabled`

Specifies whether Amazon EBS volumes are attached to data nodes in the Amazon ES domain.

Required: No

Type: Boolean

`Iops`

The number of I/O operations per second (IOPS) that the volume supports. This property applies only to the Provisioned IOPS (SSD) EBS volume type.

Required: No

Type: Integer

`VolumeSize`

The size of the EBS volume for each data node. The minimum and maximum size of an EBS volume depends on the EBS volume type and the instance type to which it is attached. For more information, see Configuring EBS-based Storage in the *Amazon Elasticsearch Service Developer Guide*.

Required: No

Type: Integer

`VolumeType`

The EBS volume type to use with the Amazon ES domain, such as `standard`, `gp2`, or `io1`. For more information about each type, see Amazon EBS Volume Types in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: String

Amazon Elasticsearch Service Domain ElasticsearchClusterConfig

`ElasticsearchClusterConfig` is a property of the AWS::Elasticsearch::Domain (p. 1412) resource that configures the cluster of an Amazon Elasticsearch Service (Amazon ES) domain.

Syntax

JSON

```
{
  "DedicatedMasterCount" : Integer,
  "DedicatedMasterEnabled" : Boolean,
  "DedicatedMasterType" : String,
  "InstanceCount" : Integer,
  "InstanceType" : String,
  "ZoneAwarenessEnabled" : Boolean
}
```

YAML

```
DedicatedMasterCount: Integer
DedicatedMasterEnabled: Boolean
DedicatedMasterType: String
InstanceCount: Integer
InstanceType: String
ZoneAwarenessEnabled: Boolean
```

Properties

`DedicatedMasterCount`

The number of instances to use for the master node.

If you specify this property, you must specify `true` for the `DedicatedMasterEnabled` property

Required: No

Type: Integer

`DedicatedMasterEnabled`

Indicates whether to use a dedicated master node for the Amazon ES domain. A dedicated master node is a cluster node that performs cluster management tasks, but doesn't hold data or respond to data upload requests. Dedicated master nodes offload cluster management tasks to increase the stability of your search clusters.

Required: No

Type: Boolean

`DedicatedMasterType`

The hardware configuration of the computer that hosts the dedicated master node, such as `m3.medium.elasticsearch`. For valid values, see Configuring Amazon ES Domains in the *Amazon Elasticsearch Service Developer Guide*.

If you specify this property, you must specify `true` for the `DedicatedMasterEnabled` property

Required: No

Type: String

`InstanceCount`

The number of data nodes (instances) to use in the Amazon ES domain.

Required: No

Type: Integer

`InstanceType`

The instance type for your data nodes, such as `m3.medium.elasticsearch`. For valid values, see Configuring Amazon ES Domains in the *Amazon Elasticsearch Service Developer Guide*.

Required: No

Type: String

`ZoneAwarenessEnabled`

Indicates whether to enable zone awareness for the Amazon ES domain. When you enable zone awareness, Amazon ES allocates the nodes and replica index shards that belong to a cluster across two Availability Zones (AZs) in the same region to prevent data loss and minimize downtime in the event of node or data center failure. Don't enable zone awareness if your cluster has no replica index shards or is a single-node cluster. For more information, see Enabling Zone Awareness in the *Amazon Elasticsearch Service Developer Guide*.

Required: No

Type: Boolean

Amazon Elasticsearch Service Domain EncryptionAtRestOptions

The `EncryptionAtRestOptions` property type specifies whether the domain should encrypt data at rest, and if so, the AWS Key Management Service (KMS) key to use. Can only be used to create a new domain, not update an existing one.

`EncryptionAtRestOptions` is a property of the AWS::Elasticsearch::Domain (p. 1412) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Enabled" : Boolean,
  "KmsKeyId" : String
}
```

YAML

```
Enabled: Boolean
KmsKeyId: String
```

Properties

`Enabled`

Specify `true` to enable encryption at rest.

Required: No

Type: Boolean

Update requires: Replacement (p. 120)

`KmsKeyId`

The KMS key ID. Takes the form `1a2a3a4-1a2a-3a4a-5a6a-1a2a3a4a5a6a`.

Required: No

Type: String

Update requires: Replacement (p. 120)

- CreateElasticsearchDomain in the *Amazon Elasticsearch Service Developer Guide*

Amazon Elasticsearch Service Domain SnapshotOptions

`SnapshotOptions` is a property of the AWS::Elasticsearch::Domain (p. 1412) resource that configures the automated snapshot of Amazon Elasticsearch Service (Amazon ES) domain indices.

Syntax

JSON

```
{
  "AutomatedSnapshotStartHour" : Integer
}
```

YAML

```
AutomatedSnapshotStartHour: Integer
```

Properties

`AutomatedSnapshotStartHour`

The hour in UTC during which the service takes an automated daily snapshot of the indices in the Amazon ES domain. For example, if you specify `0`, Amazon ES takes an automated snapshot everyday between midnight and 1 am. You can specify a value between `0` and `23`.

Required: No

Type: Integer

Amazon Elasticsearch Service Domain VPCOptions

The `VPCOptions` property type specifies a virtual private cloud (VPC) configuration for an Amazon Elasticsearch Service (Amazon ES) domain.

`VPCOptions` is a property of the AWS::Elasticsearch::Domain (p. 1412) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SecurityGroupIds" : [ String, ... ],
  "SubnetIds" : [ String, ... ]
}
```

YAML

```
SecurityGroupIds:
  - String
SubnetIds:
  - String
```

Properties

`SecurityGroupIds`

The list of security group IDs that are associated with the VPC endpoints for the domain. If you don't provide a security group ID, Amazon ES uses the default security group for the VPC. To learn more, see Security Groups for your VPC in the *Amazon VPC User Guide*.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SubnetIds`

A list of subnet IDs that are associated with the VPC endpoints for the domain. If your domain has zone awareness enabled, you need to provide two subnet IDs, one per zone. Otherwise, provide only one. To learn more, see VPCs and Subnets in the *Amazon VPC User Guide*.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

- VPC Support for Amazon Elasticsearch Service Domains in the *Amazon Elasticsearch Service Developer Guide*

AWS Elastic Beanstalk Resource Types Reference

This section contains reference information for all AWS Elastic Beanstalk resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::ElasticBeanstalk::data-type-name
```

Topics

- AWS::ElasticBeanstalk::Application (p. 1425)
- AWS::ElasticBeanstalk::ApplicationVersion (p. 1430)
- AWS::ElasticBeanstalk::ConfigurationTemplate (p. 1433)
- AWS::ElasticBeanstalk::Environment (p. 1438)

AWS::ElasticBeanstalk::Application

Creates an Elastic Beanstalk application.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::ElasticBeanstalk::Application",
   "Properties" : {
      "ApplicationName" : String,
      "Description" : String,
      "ResourceLifecycleConfig" : ApplicationResourceLifecycleConfig (p. 1427)

   }
}
```

YAML

```
Type: AWS::ElasticBeanstalk::Application
Properties:
  ApplicationName: String
  Description: String
  ResourceLifecycleConfig:
```

```
    ApplicationResourceLifecycleConfig (p. 1427)
```

Properties

`ApplicationName`

A name for the Elastic Beanstalk application. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the application name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Description`

An optional description of this application.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ResourceLifecycleConfig`

Defines lifecycle settings for resources that belong to the application, and the service role that Elastic Beanstalk assumes in order to apply lifecycle settings.

Required: No

Type: ApplicationResourceLifecycleConfig (p. 1427)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "Type" : "AWS::ElasticBeanstalk::Application",
   "Properties" : {
      "ApplicationName" : "SampleAWSElasticBeanstalkApplication",
      "Description" : "AWS Elastic Beanstalk PHP Sample Application"
   }
```

```
}
```

YAML

```
Type: AWS::ElasticBeanstalk::Application
Properties:
  ApplicationName: "SampleAWSElasticBeanstalkApplication"
  Description: "AWS Elastic Beanstalk PHP Sample Application"
```

See Also

- For a complete Elastic Beanstalk sample template, see Elastic Beanstalk Template Snippets (p. 390).

AWS Elastic Beanstalk Application ApplicationResourceLifecycleConfig

The `ApplicationResourceLifecycleConfig` property type specifies lifecycle settings for resources that belong to the application, and the service role that AWS Elastic Beanstalk assumes in order to apply lifecycle settings.

`ApplicationResourceLifecycleConfig` is a property of the AWS::ElasticBeanstalk::Application (p. 1425) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ServiceRole" : String,
  "VersionLifecycleConfig" : ApplicationVersionLifecycleConfig (p. 1428)
}
```

YAML

```
ServiceRole: String
VersionLifecycleConfig:
  ApplicationVersionLifecycleConfig
```

Properties

`ServiceRole`

The ARN of an IAM service role that Elastic Beanstalk has permission to assume.

Required: Conditional. If you specify the `VersionLifecycleConfig` property, you must specify this property.

Type: String

Update requires: No interruption (p. 120)

`VersionLifecycleConfig`

Defines lifecycle settings for application versions.

Required: No

Type: ApplicationVersionLifecycleConfig (p. 1428)

Update requires: No interruption (p. 120)

AWS Elastic Beanstalk Application ApplicationVersionLifecycleConfig

The `ApplicationVersionLifecycleConfig` property type specifies the application version lifecycle settings for an AWS Elastic Beanstalk application. It defines the rules that Elastic Beanstalk applies to an application's versions in order to avoid hitting the per-region limit for application versions.

When Elastic Beanstalk deletes an application version from its database, you can no longer deploy that version to an environment. The source bundle remains in S3 unless you configure the rule to delete it.

`ApplicationVersionLifecycleConfig` is a property of the ApplicationResourceLifecycleConfig (p. 1427) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "MaxAgeRule" : MaxAgeRule (p. 1428),
  "MaxCountRule" : MaxCountRule (p. 1429)
}
```

YAML

```
MaxAgeRule: MaxAgeRule
MaxCountRule: MaxCountRule
```

Properties

`MaxAgeRule`

Specifies a max age rule to restrict the length of time that application versions are retained for an application.

Required: No

Type: MaxAgeRule (p. 1428)

Update requires: No interruption (p. 120)

`MaxCountRule`

Specifies a max count rule to restrict the number of application versions that are retained for an application.

Required: No

Type: MaxCountRule (p. 1429)

Update requires: No interruption (p. 120)

AWS Elastic Beanstalk Application MaxAgeRule

The `MaxAgeRule` property type specifies a lifecycle rule that deletes application versions after the specified number of days for an AWS Elastic Beanstalk application.

`MaxAgeRule` is a property of the ApplicationVersionLifecycleConfig (p. 1428) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "DeleteSourceFromS3" : Boolean,
  "Enabled" : Boolean,
  "MaxAgeInDays" : Integer
}
```

YAML

```
DeleteSourceFromS3: Boolean
Enabled: Boolean
MaxAgeInDays: Integer
```

Properties

`DeleteSourceFromS3`

Set to `true` to delete a version's source bundle from Amazon S3 when Elastic Beanstalk deletes the application version.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Enabled`

Specify `true` to apply the rule, or `false` to disable it.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`MaxAgeInDays`

Specify the number of days to retain an application versions.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

AWS Elastic Beanstalk Application MaxCountRule

The `MaxCountRule` property type specifies a lifecycle rule that deletes the oldest application version when the maximum count is exceeded for an AWS Elastic Beanstalk application.

`MaxCountRule` is a property of the ApplicationVersionLifecycleConfig (p. 1428) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "DeleteSourceFromS3" : Boolean,
  "Enabled" : Boolean,
  "MaxCount" : Integer
}
```

YAML

```
DeleteSourceFromS3: Boolean
Enabled: Boolean
MaxCount: Integer
```

Properties

`DeleteSourceFromS3`

Set to `true` to delete a version's source bundle from Amazon S3 when Elastic Beanstalk deletes the application version.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Enabled`

Specify `true` to apply the rule, or `false` to disable it.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`MaxCount`

Specify the maximum number of application versions to retain.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

AWS::ElasticBeanstalk::ApplicationVersion

Creates an application version, an iteration of deployable code, for an Elastic Beanstalk application.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElasticBeanstalk::ApplicationVersion",
  "Properties" : {
    "ApplicationName" : String,
    "Description" : String,
    "SourceBundle" : { SourceBundle }
  }
}
```

YAML

```
Type: AWS::ElasticBeanstalk::ApplicationVersion
Properties:
  ApplicationName: String
  Description: String
  SourceBundle:
    SourceBundle
```

Members

`ApplicationName`

Name of the Elastic Beanstalk application that is associated with this application version.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Description`

A description of this application version.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`SourceBundle`

The location of the source bundle for this version.

Required: Yes

Type: Source Bundle (p. 1432)

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
"myAppVersion" :{
  "Type" : "AWS::ElasticBeanstalk::ApplicationVersion",
  "Properties" : {
    "ApplicationName" : {"Ref" : "myApp"},
    "Description" : "my sample version",
    "SourceBundle" : {
      "S3Bucket" : { "Fn::Join" :
        ["-", [ "elasticbeanstalk-samples", { "Ref" : "AWS::Region" } ] ] },
      "S3Key" : "php-newsample-app.zip"
    }
  }
}
```

YAML

```
myAppVersion:
  Type: AWS::ElasticBeanstalk::ApplicationVersion
  Properties:
    ApplicationName:
      Ref: "myApp"
    Description: "my sample version"
    SourceBundle:
      S3Bucket:
        Fn::Join:
          - "-"
          -
            - "elasticbeanstalk-samples"
            - Ref: "AWS::Region"
      S3Key: "php-newsample-app.zip"
```

See Also

- For a complete Elastic Beanstalk sample template, see Elastic Beanstalk Template Snippets (p. 390).

Elastic Beanstalk ApplicationVersion SourceBundle

The `SourceBundle` property is an embedded property of the AWS::ElasticBeanstalk::ApplicationVersion (p. 1430) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "S3Bucket (p. 1433)" : String,
   "S3Key (p. 1433)" : String
}
```

YAML

```
S3Bucket (p. 1433): String
S3Key (p. 1433): String
```

Members

`S3Bucket`

The Amazon S3 bucket where the data is located.

Required: Yes

Type: String

`S3Key`

The Amazon S3 key where the data is located.

Required: Yes

Type: String

AWS::ElasticBeanstalk::ConfigurationTemplate

Creates a configuration template for an Elastic Beanstalk application. You can use configuration templates to deploy different versions of an application by using the configuration settings that you define in the configuration template.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElasticBeanstalk::ConfigurationTemplate",
  "Properties" : {
    "ApplicationName" : String,
    "Description" : String,
    "EnvironmentId" : String,
    "OptionSettings" : [ ConfigurationOptionSetting (p. 1436), ... ],
    "PlatformArn" : String,
    "SolutionStackName" : String,
    "SourceConfiguration" : SourceConfiguration (p. 1437)
  }
}
```

YAML

```
Type: AWS::ElasticBeanstalk::ConfigurationTemplate
Properties:
  ApplicationName: String
  Description: String
  EnvironmentId: String
  OptionSettings:
    - ConfigurationOptionSetting (p. 1436)
  PlatformArn: String
  SolutionStackName: String
  SourceConfiguration:
    SourceConfiguration (p. 1437)
```

Properties

For more information, see CreateConfigurationTemplate in the *AWS Elastic Beanstalk API Reference*.

`ApplicationName`

Name of the Elastic Beanstalk application that is associated with this configuration template.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Description`

An optional description for this configuration.

Type: String

Required: No

Update requires: Some interruptions (p. 121)

`EnvironmentId`

An environment whose settings you want to use to create the configuration template. You must specify this property if you don't specify the `SolutionStackName` or `SourceConfiguration` properties.

Type: String

Required: Conditional

Update requires: Replacement (p. 121)

`OptionSettings`

The options for the Elastic Beanstalk configuration, such as the instance type. For a complete list of Elastic Beanstalk configuration options, see Option Values, in the *AWS Elastic Beanstalk Developer Guide*.

Type: List of ConfigurationOptionSetting (p. 1436)

Required: No

Update requires: Some interruptions (p. 121)

`PlatformArn`

The Amazon Resource Name (ARN) of the custom platform. For more information, see Custom Platforms in the *AWS Elastic Beanstalk Developer Guide*.

> **Note**
> If you specify `PlatformArn`, then don't specify `SolutionStackName`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SolutionStackName`

The name of an Elastic Beanstalk solution stack that this configuration will use. A solution stack specifies the operating system, architecture, and application server for a configuration template, such as `64bit Amazon Linux 2013.09 running Tomcat 7 Java 7`. For more information, see Supported Platforms in the *AWS Elastic Beanstalk Developer Guide*.

You must specify this property if you don't specify the `PlatformArn`, `EnvironmentId`, or `SourceConfiguration` properties.

Type: String

Required: Conditional

Update requires: Replacement (p. 121)

`SourceConfiguration`

A configuration template that is associated with another Elastic Beanstalk application. If you specify the `SolutionStackName` property and the `SourceConfiguration` property, the solution stack in the source configuration template must match the value that you specified for the `SolutionStackName` property.

You must specify this property if you don't specify the `EnvironmentId` or `SolutionStackName` properties.

Type: SourceConfiguration (p. 1437)

Required: Conditional

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

This example of an ElasticBeanstalk `ConfigurationTemplate` is found in the AWS CloudFormation sample template ElasticBeanstalkSample.template, which also provides an example of its use within an `AWS::ElasticBeanstalk::Application`.

JSON

```
"myConfigTemplate" : {
  "Type" : "AWS::ElasticBeanstalk::ConfigurationTemplate",
  "Properties" : {
    "ApplicationName" :{"Ref" : "myApp"},
    "Description" : "my sample configuration template",
    "EnvironmentId" : "",
    "SourceConfiguration" : {
      "ApplicationName" : {"Ref" : "mySecondApp"},
      "TemplateName" : {"Ref" : "mySourceTemplate"}
    },
    "SolutionStackName" : "64bit Amazon Linux running PHP 5.3",
    "OptionSettings" : [ {
      "Namespace" : "aws:autoscaling:launchconfiguration",
      "OptionName" : "EC2KeyName",
      "Value" : { "Ref" : "KeyName" }
    } ]
  }
}
```

YAML

```
myConfigTemplate:
```

```
  Type: AWS::ElasticBeanstalk::ConfigurationTemplate
  Properties:
    ApplicationName:
      Ref: "myApp"
    Description: "my sample configuration template"
    EnvironmentId: ""
    SourceConfiguration:
      ApplicationName:
        Ref: "mySecondApp"
      TemplateName:
        Ref: "mySourceTemplate"
    SolutionStackName: "64bit Amazon Linux running PHP 5.3"
    OptionSettings:
      -
        Namespace: "aws:autoscaling:launchconfiguration"
        OptionName: "EC2KeyName"
        Value:
          Ref: "KeyName"
```

AWS Elastic Beanstalk ConfigurationTemplate ConfigurationOptionSetting

The `ConfigurationOptionSetting` property type specifies an option for an AWS Elastic Beanstalk configuration template.

The `OptionSettings` property of the AWS::ElasticBeanstalk::ConfigurationTemplate (p. 1433) resource contains a list of `ConfigurationOptionSetting` property types.

Syntax

JSON

```
{
   "Namespace" : String,
   "OptionName" : String,
   "ResourceName" : String,
   "Value" : String
}
```

YAML

```
Namespace: String
OptionName: String
ResourceName: String
Value: String
```

Properties

`Namespace`

A unique namespace that identifies the option's associated AWS resource. For a list of namespaces that you can use, see Configuration Options in the *AWS Elastic Beanstalk Developer Guide*.

Required: Yes

Type: String

`OptionName`

The name of the configuration option. For a list of options that you can use, see Configuration Options in the *AWS Elastic Beanstalk Developer Guide*.

Required: Yes

Type: String

`ResourceName`

A unique resource name for the option setting. Use this property for a time–based scaling configuration option.

Required: No

Type: String

`Value`

The current value for the configuration option.

Required: No

Type: String

See Also

- ConfigurationOptionSetting in the *AWS Elastic Beanstalk Developer Guide*
- Configuration Options in the *AWS Elastic Beanstalk Developer Guide*

AWS Elastic Beanstalk ConfigurationTemplate SourceConfiguration

Use settings from another Elastic Beanstalk configuration template for the AWS::ElasticBeanstalk::ConfigurationTemplate (p. 1433) resource type.

Syntax

JSON

```
{
   "ApplicationName" : String,
   "TemplateName" : String
}
```

YAML

```
ApplicationName: String
TemplateName: String
```

Properties

`ApplicationName`

The name of the Elastic Beanstalk application that contains the configuration template that you want to use.

Required: Yes

Type: String

`TemplateName`

The name of the configuration template.

Required: Yes

Type: String

AWS::ElasticBeanstalk::Environment

Creates or updates an AWS Elastic Beanstalk environment.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::ElasticBeanstalk::Environment",
   "Properties" : {
      "ApplicationName (p. 1439)" : String,
      "CNAMEPrefix (p. 1439)" : String,
      "Description (p. 1439)" :  String,
      "EnvironmentName" :  String,
      "OptionSettings (p. 1439)" : [ OptionSetting, ... ],
      "PlatformArn" : String,
      "SolutionStackName (p. 1440)" : String,
      "Tags" : [ Resource Tag, ... ],
      "TemplateName (p. 1440)" : String,
      "Tier" : Environment Tier,
      "VersionLabel (p. 1440)" : String
   }
}
```

YAML

```
Type: AWS::ElasticBeanstalk::Environment
Properties:
  ApplicationName (p. 1439): String
  CNAMEPrefix (p. 1439): String
  Description (p. 1439): String
  EnvironmentName: String
  OptionSettings (p. 1439):
    - OptionSetting
  PlatformArn: String
  SolutionStackName (p. 1440): String
  Tags:
    - Resource Tag, ...
  TemplateName (p. 1440): String
  Tier:
    Environment Tier
  VersionLabel (p. 1440): String
```

Properties

For more information, see CreateEnvironment in the *AWS Elastic Beanstalk API Reference*.

`ApplicationName`

The name of the application that is associated with this environment.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`CNAMEPrefix`

A prefix for your Elastic Beanstalk environment URL.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Description`

A description that helps you identify this environment.

Required: No

Type: String

Update requires: No interruption (p. 120)

`EnvironmentName`

A name for the Elastic Beanstalk environment. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the environment name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`OptionSettings`

Key-value pairs defining configuration options for this environment, such as the instance type. These options override the values that are defined in the solution stack or the configuration template (p. 1433). If you remove any options during a stack update, the removed options revert to default values.

Required: Yes. The `IamInstanceProfile` and `ServiceRole` options are required.

Type: List of OptionSetting (p. 1451)

Update requires: Some interruptions (p. 121)

`PlatformArn`

The Amazon Resource Name (ARN) of the custom platform to use with the environment. For more information, see Custom Platforms in the *AWS Elastic Beanstalk Developer Guide*.

Note
If you specify `PlatformArn`, then don't specify `SolutionStackName`.

Required: No

Type: String

Update requires: No interruption (p. 120)

Example: `"PlatformArn": "arn:aws:elasticbeanstalk:us-east-1::platform/PHP 5.4 running on 64bit Amazon Linux/2.4.4"`

`SolutionStackName`

The name of an Elastic Beanstalk solution stack that this configuration will use. For more information, see Supported Platforms in the *AWS Elastic Beanstalk Developer Guide*.

Note
If you specify `SolutionStackName`, then don't specify `PlatformArn` or `TemplateName`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) for this environment.

Required: No

Type: Resource Tag (p. 2258)

Update requires: You can update tags only if you update another property that requires that the environment be replaced, such as the `ApplicationName` property.

`TemplateName`

The name of the Elastic Beanstalk configuration template to use with the environment.

Note
If you specify `TemplateName`, then don't specify `SolutionStackName`.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`Tier`

Specifies the tier to use in creating this environment. The environment tier that you choose determines whether Elastic Beanstalk provisions resources to support a web application that handles HTTP(S) requests or a web application that handles background-processing tasks.

Required: No

Type: Elastic Beanstalk Environment EnvironmentTier (p. 1450)

Update requires: See Elastic Beanstalk Environment EnvironmentTier (p. 1450)

`VersionLabel`

The version to associate with the environment.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`EndpointURL`

For load-balanced, autoscaling environments, the URL to the load balancer. For single-instance environments, the IP address of the instance.

Example load balancer URL:

`awseb-myst-myen-132MQC4KRLAMD-1371280482.us-east-2.elb.amazonaws.com`

Example instance IP address:

`192.0.2.0`

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Simple Environment

JSON

```
{
   "Type" : "AWS::ElasticBeanstalk::Environment",
   "Properties" : {
      "ApplicationName" : { "Ref" : "sampleApplication" },
      "Description" :  "AWS Elastic Beanstalk Environment running PHP Sample Application",
      "EnvironmentName" :  "SamplePHPEnvironment",
      "TemplateName" : "DefaultConfiguration",
      "VersionLabel" : "Initial Version"
   }
}
```

YAML

```
Type: AWS::ElasticBeanstalk::Environment
Properties:
  ApplicationName:
    Ref: sampleApplication
```

```
  Description: "AWS Elastic Beanstalk Environment running PHP Sample Application"
  EnvironmentName: SamplePHPEnvironment
  TemplateName: DefaultConfiguration
  VersionLabel: "Initial Version"
```

Environment with Embedded Option Settings

JSON

```
{
   "Type" : "AWS::ElasticBeanstalk::Environment",
   "Properties" : {
      "ApplicationName" : { "Ref" : "sampleApplication" },
      "Description" :  "AWS Elastic Beanstalk Environment running Python Sample
 Application",
      "EnvironmentName" :  "SamplePythonEnvironment",
      "SolutionStackName" : "64bit Amazon Linux 2017.03 v2.5.0 running Python 2.7",
      "OptionSettings" : [ {
         "Namespace" : "aws:autoscaling:launchconfiguration",
         "OptionName" : "EC2KeyName",
         "Value" : { "Ref" : "KeyName" }
      } ],
      "VersionLabel" : "Initial Version"
   }
}
```

YAML

```
Type: AWS::ElasticBeanstalk::Environment
Properties:
  ApplicationName:
    Ref: sampleApplication
  Description: "AWS Elastic Beanstalk Environment running Python Sample Application"
  EnvironmentName: SamplePythonEnvironment
  SolutionStackName: "64bit Amazon Linux 2017.03 v2.5.0 running Python 2.7"
  OptionSettings:
    -
      Namespace: "aws:autoscaling:launchconfiguration"
      OptionName: EC2KeyName
      Value:
        Ref: KeyName
  VersionLabel: "Initial Version"
```

Custom or Supported Platform

The following example contains parameters that enable specifying `PlatformArn` for a custom platform or `SolutionStackName` for a supported platform when creating the stack.

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Description": "Elasticbeanstalk test template",
  "Parameters": {
    "BeanstalkService": {
      "Type": "String"
    },
    "Ec2Service": {
      "Type": "String"
    },
```

```
    "Partition":{
      "Type": "String"
    },
    "SolutionStackName": {
      "Type": "String"
    },
    "PlatformArn": {
      "Type": "String"
    }
  },
  "Resources": {
    "Application": {
      "Properties": {
        "ApplicationVersions": [
          {
            "Description": "Version 1.0",
            "SourceBundle": {
              "S3Bucket": {
                "Fn::Join": ["", ["elasticbeanstalk-samples-", {"Ref": "AWS::Region"}]]
              },
              "S3Key": "python-sample-20150402.zip"
            },
            "VersionLabel": "Initial Version"
          }
        ],
        "Description": "AWS Elastic Beanstalk Python Sample Application"
      },
      "Type": "AWS::ElasticBeanstalk::Application"
    },
    "Environment": {
      "Properties": {
        "ApplicationName": {
          "Ref": "Application"
        },
        "Description": "AWS Elastic Beanstalk Environment running Python Sample
Application",
        "PlatformArn": { "Ref" : "PlatformArn"},
        "SolutionStackName": {
          "Ref": "SolutionStackName"
        },
        "VersionLabel": "Initial Version",
        "OptionSettings": [
          {
            "Namespace": "aws:autoscaling:launchconfiguration",
            "OptionName": "IamInstanceProfile",
            "Value": {
              "Ref": "InstanceProfile"
            }
          },
          {
            "Namespace": "aws:elasticbeanstalk:environment",
            "OptionName": "ServiceRole",
            "Value": {
              "Ref": "ServiceRole"
            }
          }
        ]
      },
      "Type": "AWS::ElasticBeanstalk::Environment"
    },
    "ServiceRole": {
      "Type": "AWS::IAM::Role",
      "Properties": {
        "AssumeRolePolicyDocument": {
          "Version": "2012-10-17",
          "Statement": [
```

```
            {
              "Sid": "",
              "Effect": "Allow",
              "Principal": {
                "Service": {"Ref": "BeanstalkService"}
              },
              "Action": "sts:AssumeRole",
              "Condition": {
                "StringEquals": {
                  "sts:ExternalId": "elasticbeanstalk"
                }
              }
            }
          ]
        },
        "Policies": [
          {
            "PolicyName": "root",
            "PolicyDocument": {
              "Version": "2012-10-17",
              "Statement": [
                {
                  "Effect": "Allow",
                  "Action": [
                    "elasticloadbalancing:DescribeInstanceHealth",
                    "ec2:DescribeInstances",

                  ],
                  "Effect": "Allow",
                  "Resource": [
                    {
                      "Fn::Join": [
                        "",
                        [
                          "arn:",
                          {
                            "Ref": "Partition"
                          },
                          ":s3:::elasticbeanstalk-*-",
                          {
                            "Ref": "AWS::AccountId"
                          }
                        ]
                      ]
                    },
                    {
                      "Fn::Join": [
                        "",
                        [
                          "arn:",
                          {
                            "Ref": "Partition"
                          },
                          ":s3:::elasticbeanstalk-*-",
                          {
                            "Ref": "AWS::AccountId"

Elastic Beanstalk Environment EnvironmentTier

Describes the environment tier for an AWS::ElasticBeanstalk::Environment (p. 1438) resource. For more information, see Environment Tiers in the *AWS Elastic Beanstalk Developer Guide*.

Syntax

JSON

```
{
   "Name" : String,
   "Type" : String,
   "Version" : String
}
```

YAML

```
Name: String
Type: String
Version: String
```

Members

`Name`

The name of the environment tier. You can specify `WebServer` or `Worker`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Type`

The type of this environment tier. You can specify `Standard` for the `WebServer` tier or `SQS/HTTP` for the `Worker` tier.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Version`

The version of this environment tier. If you don't specify this member, the latest compatible worker tier version is used.

> **Note**
> This member is deprecated. Any specific version that you specify may become outdated. We recommend leaving this unspecified.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Elastic Beanstalk Environment OptionSetting

The `OptionSetting` property type specifies an option for an AWS Elastic Beanstalk environment.

The `OptionSettings` property of the AWS::ElasticBeanstalk::Environment (p. 1438) resource contains a list of `OptionSetting` property types.

Syntax

JSON

```
{
   "Namespace (p. 1451)" : String,
   "OptionName (p. 1452)" : String,
   "ResourceName" : String,
   "Value (p. 1452)" : String
}
```

YAML

```
Namespace (p. 1451): String
OptionName (p. 1452): String
ResourceName: String
Value (p. 1452): String
```

Properties

`Namespace`

A unique namespace that identifies the option's associated AWS resource. For a list of namespaces that you can use, see Configuration Options in the *AWS Elastic Beanstalk Developer Guide*.

Required: Yes

Type: String

`OptionName`

The name of the configuration option. For a list of options that you can use, see Configuration Options in the *AWS Elastic Beanstalk Developer Guide*.

Required: Yes

Type: String

`ResourceName`

A unique resource name for the option setting. Use this property for a time–based scaling configuration option.

Required: No

Type: String

`Value`

The current value for the configuration option.

Required: No

Type: String

Elastic Load Balancing Resource Types Reference

This section contains reference information for all Elastic Load Balancing resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::ElasticLoadBalancing::data-type-name
```

Topics

- AWS::ElasticLoadBalancing::LoadBalancer (p. 1452)

AWS::ElasticLoadBalancing::LoadBalancer

The AWS::ElasticLoadBalancing::LoadBalancer type creates a LoadBalancer.

> **Note**
> If this resource has a public IP address and is also in a VPC that is defined in the same template, you must use the `DependsOn` attribute to declare a dependency on the VPC-gateway attachment. For more information, see DependsOn Attribute (p. 2275).

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type": "AWS::ElasticLoadBalancing::LoadBalancer",
   "Properties": {
      "AccessLoggingPolicy" : AccessLoggingPolicy,
      "AppCookieStickinessPolicy (p. 1454)" : [ AppCookieStickinessPolicy, ... ],
      "AvailabilityZones (p. 1454)" : [ String, ... ],
      "ConnectionDrainingPolicy" : ConnectionDrainingPolicy,
      "ConnectionSettings" : ConnectionSettings,
      "CrossZone" : Boolean,
      "HealthCheck (p. 1455)" : HealthCheck,
      "Instances (p. 1455)" : [ String, ... ],
      "LBCookieStickinessPolicy (p. 1455)" : [ LBCookieStickinessPolicy, ... ],
      "Listeners (p. 1455)" : [ Listener, ... ],
      "LoadBalancerName (p. 1455)" : String,
      "Policies (p. 1456)" : [ ElasticLoadBalancing Policy, ... ],
      "Scheme (p. 1456)" : String,
      "SecurityGroups (p. 1456)" : [ Security Group, ... ],
      "Subnets (p. 1456)" : [ String, ... ],
      "Tags" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::ElasticLoadBalancing::LoadBalancer
Properties:
  AccessLoggingPolicy:
    AccessLoggingPolicy
  AppCookieStickinessPolicy (p. 1454):
    - AppCookieStickinessPolicy
  AvailabilityZones (p. 1454):
    - String
  ConnectionDrainingPolicy:
    ConnectionDrainingPolicy
  ConnectionSettings:
    ConnectionSettings
  CrossZone: Boolean
  HealthCheck (p. 1455):
    HealthCheck
  Instances (p. 1455):
    - String
  LBCookieStickinessPolicy (p. 1455):
    - LBCookieStickinessPolicy
  Listeners (p. 1455):
    - Listener
  LoadBalancerName: String
  Policies (p. 1456):
    - ElasticLoadBalancing Policy
  Scheme (p. 1456): String,
  SecurityGroups (p. 1456):
    - Security Group
  Subnets (p. 1456):
    - String
  Tags:
    - Resource Tag
```

Properties

`AccessLoggingPolicy`

Captures detailed information for all requests made to your load balancer, such as the time a request was received, client's IP address, latencies, request path, and server responses.

Required: No

Type: Elastic Load Balancing AccessLoggingPolicy (p. 1464)

Update requires: No interruption (p. 120)

`AppCookieStickinessPolicy`

Generates one or more stickiness policies with sticky session lifetimes that follow that of an application-generated cookie. These policies can be associated only with HTTP/HTTPS listeners.

Required: No

Type: A list of AppCookieStickinessPolicy (p. 1465) objects.

Update requires: No interruption (p. 120)

`AvailabilityZones`

The Availability Zones in which to create the load balancer. You can specify the `AvailabilityZones` or `Subnets` property, but not both.

> **Note**
> For load balancers that are in a VPC, specify the `Subnets` property.

Required: No

Type: List of String values

Update requires: Replacement (p. 121) if you did not have an Availability Zone specified and you are adding one or if you are removing all Availability Zones. Otherwise, update requires no interruption (p. 120).

`ConnectionDrainingPolicy`

Whether deregistered or unhealthy instances can complete all in-flight requests.

Required: No

Type: Elastic Load Balancing ConnectionDrainingPolicy (p. 1465)

Update requires: No interruption (p. 120)

`ConnectionSettings`

Specifies how long front-end and back-end connections of your load balancer can remain idle.

Required: No

Type: Elastic Load Balancing ConnectionSettings (p. 1466)

Update requires: No interruption (p. 120)

`CrossZone`

Whether cross-zone load balancing is enabled for the load balancer. With cross-zone load balancing, your load balancer nodes route traffic to the back-end instances across all Availability Zones. By default the `CrossZone` property is `false`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`HealthCheck`

Application health check for the instances.

Required: No

Type: ElasticLoadBalancing LoadBalancer HealthCheck (p. 1467).

Update requires: Replacement (p. 121) if you did not have a health check specified and you are adding one or if you are removing a health check. Otherwise, update requires no interruption (p. 120).

`Instances`

A list of EC2 instance IDs for the load balancer.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`LBCookieStickinessPolicy`

Generates a stickiness policy with sticky session lifetimes controlled by the lifetime of the browser (user-agent), or by a specified expiration period. This policy can be associated only with HTTP/HTTPS listeners.

Required: No

Type: A list of LBCookieStickinessPolicy (p. 1468) objects.

Update requires: No interruption (p. 120)

`Listeners`

One or more listeners for this load balancer. Each listener must be registered for a specific port, and you cannot have more than one listener for a given port.

> **Important**
> If you update the property values for a listener specified by the `Listeners` property, AWS CloudFormation will delete the existing listener and create a new one with the updated properties. During the time that AWS CloudFormation is performing this action, clients will not be able to connect to the load balancer.

Required: Yes

Type: A list of ElasticLoadBalancing Listener (p. 1469) objects.

Update requires: No interruption (p. 120)

`LoadBalancerName`

A name for the load balancer. For valid values, see the `LoadBalancerName` parameter for the `CreateLoadBalancer` action in the *Elastic Load Balancing API Reference version 2012-06-01*.

If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the load balancer. The name must be unique within your set of load balancers. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Policies`

A list of elastic load balancing policies to apply to this elastic load balancer. Specify only back-end server policies. For more information, see DescribeLoadBalancerPolicyTypes in the *Elastic Load Balancing API Reference version 2012-06-01*.

Required: No

Type: A list of ElasticLoadBalancing policy (p. 1471) objects.

Update requires: No interruption (p. 120)

`Scheme`

For load balancers attached to an Amazon VPC, this parameter can be used to specify the type of load balancer to use. Specify `internal` to create an internal load balancer with a DNS name that resolves to private IP addresses or `internet-facing` to create a load balancer with a publicly resolvable DNS name, which resolves to public IP addresses.

> **Note**
> If you specify `internal`, you must specify subnets to associate with the load balancer, not Availability Zones.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SecurityGroups`

Required: No

Type: A list of security groups assigned to your load balancer within your virtual private cloud (VPC).

Update requires: No interruption (p. 120)

`Subnets`

A list of subnet IDs in your virtual private cloud (VPC) to attach to your load balancer. Do not specify multiple subnets that are in the same Availability Zone. You can specify the `AvailabilityZones` or `Subnets` property, but not both.

For more information about using Elastic Load Balancing in a VPC, see How Do I Use Elastic Load Balancing in Amazon VPC in the *Elastic Load Balancing Developer Guide*.

Required: No

Type: List of String values

Update requires: Replacement (p. 121) if you did not have a subnet specified and you are adding one or if you are removing all subnets. Otherwise, update requires no interruption (p. 120). To update the load balancer to another subnet that is in the same Availability Zone, you must do two updates. You must first update the load balancer to use a subnet in different Availability Zone. After the update is complete, update the load balancer to use the new subnet that is in the original Availability Zone.

`Tags`

An arbitrary set of tags (key-value pairs) for this load balancer.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example, `mystack-myelb-1WQN7BJGDB5YQ`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`CanonicalHostedZoneName`

The name of the Route 53 hosted zone that is associated with the load balancer.

> **Important**
> If you specify `internal` for the Elastic Load Balancing scheme, use `DNSName` instead. For an `internal` scheme, the load balancer doesn't have a `CanonicalHostedZoneName` value.

Example: `mystack-myelb-15HMABG9ZCN57-1013119603.us-east-2.elb.amazonaws.com`

`CanonicalHostedZoneNameID`

The ID of the Route 53 hosted zone name that is associated with the load balancer.

Example: `Z3DZXE0Q79N41H`

`DNSName`

The DNS name for the load balancer.

Example: `mystack-myelb-15HMABG9ZCN57-1013119603.us-east-2.elb.amazonaws.com`

`SourceSecurityGroup.GroupName`

The security group that you can use as part of your inbound rules for your load balancer's back-end Amazon EC2 application instances.

Example: `amazon-elb`

`SourceSecurityGroup.OwnerAlias`

The owner of the source security group.

Example: `amazon-elb-sg`

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

A load balancer with a health check and access logs

    DependsOn: S3LoggingBucketPolicy
```

A load balancer with access logging enabled

The following sample snippet creates an Amazon S3 bucket with a bucket policy that allows the load balancer to store information in the `Logs/AWSLogs/`*`AWS account number`*`/` folder. The load balancer

also includes an explicit dependency on the bucket policy, which is required before the load balancer can write to the bucket.

A load balancer with a connection draining policy

The following snippet enables a connection draining policy that ends connections to a deregistered or unhealthy instance after 60 seconds.

JSON

```
"ElasticLoadBalancer" : {
```

```
  "Type" : "AWS::ElasticLoadBalancing::LoadBalancer",
  "Properties" : {
    "AvailabilityZones" : { "Fn::GetAZs" : "" },
    "Instances" : [ { "Ref" : "Ec2Instance1" },{ "Ref" : "Ec2Instance2" } ],
    "Listeners": [{
      "LoadBalancerPort": "80",
      "InstancePort": "80",
      "Protocol": "HTTP"
    }],
    "HealthCheck": {
      "Target": "HTTP:80/",
      "HealthyThreshold": "3",
      "UnhealthyThreshold": "5",
      "Interval": "30",
      "Timeout": "5"
    },
    "ConnectionDrainingPolicy": {
      "Enabled" : "true",
      "Timeout" : "60"
    }
  }
}
```

YAML

```
ElasticLoadBalancer:
  Type: AWS::ElasticLoadBalancing::LoadBalancer
  Properties:
    AvailabilityZones:
      Fn::GetAZs: ''
    Instances:
    - Ref: Ec2Instance1
    - Ref: Ec2Instance2
    Listeners:
    - LoadBalancerPort: '80'
      InstancePort: '80'
      Protocol: HTTP
    HealthCheck:
      Target: HTTP:80/
      HealthyThreshold: '3'

Additional Examples

You can view additional examples from the AWS CloudFormation sample template collection: Sample Templates (p. 2372).

Elastic Load Balancing AccessLoggingPolicy

The `AccessLoggingPolicy` property describes where and how access logs are stored for the AWS::ElasticLoadBalancing::LoadBalancer (p. 1452) resource.

Syntax

JSON

```
{
  "EmitInterval" : Integer,
  "Enabled" : Boolean,
  "S3BucketName" : String,
  "S3BucketPrefix" : String
}
```

YAML

```
EmitInterval: Integer
Enabled: Boolean
S3BucketName: String
S3BucketPrefix: String
```

Properties

`EmitInterval`

The interval for publishing access logs in minutes. You can specify an interval of either 5 minutes or 60 minutes.

Required: No

Type: Integer

`Enabled`

Whether logging is enabled for the load balancer.

Required: Yes

Type: Boolean

`S3BucketName`

The name of an Amazon S3 bucket where access log files are stored.

Required: Yes

Type: String

`S3BucketPrefix`

A prefix for the all log object keys, such as `my-load-balancer-logs/prod`. If you store log files from multiple sources in a single bucket, you can use a prefix to distinguish each log file and its source.

Required: No

Type: String

ElasticLoadBalancing AppCookieStickinessPolicy

The AppCookieStickinessPolicy type is an embedded property of the AWS::ElasticLoadBalancing::LoadBalancer (p. 1452) type.

Syntax

JSON

```
{
   "CookieName (p. 1465)" : String,
   "PolicyName (p. 1465)" : String
}
```

YAML

```
CookieName (p. 1465): String
PolicyName (p. 1465): String
```

Properties

`CookieName`

Name of the application cookie used for stickiness.

Required: Yes

Type: String

`PolicyName`

The name of the policy being created. The name must be unique within the set of policies for this Load Balancer.

> **Note**
> To associate this policy with a listener, include the policy name in the listener's PolicyNames (p. 1469) property.

Required: Yes

Type: String

- Sample template snippets in the Examples section of AWS::ElasticLoadBalancing::LoadBalancer (p. 1452).
- CreateAppCookieStickinessPolicyin the *Elastic Load Balancing API Reference version 2012-06-01*

Elastic Load Balancing ConnectionDrainingPolicy

The `ConnectionDrainingPolicy` property describes how deregistered or unhealthy instances handle in-flight requests for the AWS::ElasticLoadBalancing::LoadBalancer (p. 1452) resource. Connection draining ensures that the load balancer completes serving all in-flight requests made to a registered

instance when the instance is deregistered or becomes unhealthy. Without connection draining, the load balancer closes connections to deregistered or unhealthy instances, and any in-flight requests are not completed.

For more information about connection draining and default values, see Enable or Disable Connection Draining for Your Load Balancer in the *Elastic Load Balancing User Guide*.

Syntax

JSON

```
{
   "Enabled" : Boolean,
   "Timeout" : Integer
}
```

YAML

```
Enabled: Boolean
Timeout: Integer
```

Properties

`Enabled`

Whether or not connection draining is enabled for the load balancer.

Required: Yes

Type: Boolean

`Timeout`

The time in seconds after the load balancer closes all connections to a deregistered or unhealthy instance.

Required: No

Type: Integer

Elastic Load Balancing ConnectionSettings

`ConnectionSettings` is a property of the AWS::ElasticLoadBalancing::LoadBalancer (p. 1452) resource that describes how long the front-end and back-end connections of your load balancer can remain idle. For more information, see Configure Idle Connection Timeout in the *Elastic Load Balancing User Guide*.

Syntax

JSON

```
{
  "IdleTimeout" : Integer
}
```

YAML

```
IdleTimeout: Integer
```

Properties

`IdleTimeout`

The time (in seconds) that a connection to the load balancer can remain idle, which means no data is sent over the connection. After the specified time, the load balancer closes the connection.

Required: Yes

Type: Integer

ElasticLoadBalancing LoadBalancer HealthCheck

The `HealthCheck` property configures health checks for the availability of your EC2 instances. For more information, see Configure Health Checks for Your Classic Load Balancer in the *User Guide for Classic Load Balancers*.

`HealthCheck` is a property of the AWS::ElasticLoadBalancing::LoadBalancer (p. 1452) resource.

Syntax

JSON

```
{
   "HealthyThreshold (p. 1467)" : String,
   "Interval (p. 1467)" : String,
   "Target (p. 1468)" : String,
   "Timeout (p. 1468)" : String,
   "UnhealthyThreshold (p. 1468)" : String
}
```

YAML

```
HealthyThreshold (p. 1467): String
Interval (p. 1467): String
Target (p. 1468): String
Timeout (p. 1468): String
UnhealthyThreshold (p. 1468): String
```

Properties

`HealthyThreshold`

Specifies the number of consecutive health probe successes required before moving the instance to the Healthy state.

Required: Yes

Type: String

`Interval`

Specifies the approximate interval, in seconds, between health checks of an individual instance. Valid values are `5` to `300`. The default is `30`.

Required: Yes

Type: String

`Target`

Specifies the instance's protocol and port to check. The protocol can be TCP, HTTP, HTTPS, or SSL. The range of valid ports is 1 through 65535.

Required: Yes

Type: String

> **Note**
> For TCP and SSL, you specify a port pair. For example, you can specify `TCP:5000` or `SSL:5000`. The health check attempts to open a TCP or SSL connection to the instance on the port that you specify. If the health check fails to connect within the configured timeout period, the instance is considered unhealthy.
> For HTTP or HTTPS, you specify a port and a path to ping (*`HTTP or HTTPS`*`:`*`port`*`/`*`PathToPing`*). For example, you can specify `HTTP:80/weather/us/wa/seattle`. In this case, an HTTP GET request is issued to the instance on the given port and path. If the health check receives any response other than `200 OK` within the configured timeout period, the instance is considered unhealthy. The total length of the HTTP or HTTPS ping target cannot be more than 1024 16-bit Unicode characters.

`Timeout`

Specifies the amount of time, in seconds, during which no response means a failed health probe. This value must be less than the value for `Interval`.

Required: Yes

Type: String

`UnhealthyThreshold`

Specifies the number of consecutive health probe failures required before moving the instance to the Unhealthy state.

Required: Yes

Type: String

ElasticLoadBalancing LBCookieStickinessPolicy

The LBCookieStickinessPolicy type is an embedded property of the AWS::ElasticLoadBalancing::LoadBalancer (p. 1452) type.

Syntax

JSON

```
{
  "CookieExpirationPeriod (p. 1469)" : String,
  "PolicyName (p. 1469)" : String
}
```

YAML

```
CookieExpirationPeriod (p. 1469): String
PolicyName (p. 1469): String
```

Properties

`CookieExpirationPeriod`

The time period, in seconds, after which the cookie should be considered stale. If this parameter isn't specified, the sticky session will last for the duration of the browser session.

Required: No

Type: String

`PolicyName`

The name of the policy being created. The name must be unique within the set of policies for this load balancer.

> **Note**
> To associate this policy with a listener, include the policy name in the listener's PolicyNames (p. 1469) property.

See Also

- Sample template snippets in the Examples section of AWS::ElasticLoadBalancing::LoadBalancer (p. 1452).
- CreateLBCookieStickinessPolicy in the *Elastic Load Balancing API Reference version 2012-06-01*

ElasticLoadBalancing Listener

The `Listener` property is an embedded property of the `AWS::ElasticLoadBalancing::LoadBalancer (p. 1452)` type.

Syntax

JSON

```
{
  "InstancePort (p. 1469)" : String,
  "InstanceProtocol (p. 1470)" : String,
  "LoadBalancerPort (p. 1470)" : String,
  "PolicyNames (p. 1470)" :  [ String, ... ],
  "Protocol (p. 1470)" : String,
  "SSLCertificateId (p. 1470)" : String
}
```

YAML

```
InstancePort (p. 1469): String
InstanceProtocol (p. 1470): String
LoadBalancerPort (p. 1470): String
PolicyNames (p. 1470):
  - String
Protocol (p. 1470): String
SSLCertificateId (p. 1470): String
```

Properties

`InstancePort`

Specifies the TCP port on which the instance server listens. You can't modify this property during the life of the load balancer.

Required: Yes

Type: String

`InstanceProtocol`

Specifies the protocol to use for routing traffic to back-end instances: HTTP, HTTPS, TCP, or SSL. You can't modify this property during the life of the load balancer.

Required: No

Type: String

Note

- If the front-end protocol is HTTP or HTTPS, `InstanceProtocol` must be on the same protocol layer (HTTP or HTTPS). Likewise, if the front-end protocol is TCP or SSL, `InstanceProtocol` must be TCP or SSL. By default, Elastic Load Balancing sets the instance protocol to HTTP or TCP.
- If there is another `Listener` with the same `InstancePort` whose `InstanceProtocol` is secure, (using HTTPS or SSL), the `InstanceProtocol` of the `Listener` must be secure (using HTTPS or SSL). If there is another `Listener` with the same `InstancePort` whose `InstanceProtocol` is HTTP or TCP, the `InstanceProtocol` of the `Listener` must be either HTTP or TCP.

`LoadBalancerPort`

Specifies the external load balancer port number. You can't modify this property during the life of the load balancer.

Required: Yes

Type: String

`PolicyNames`

A list of `ElasticLoadBalancing` policy (p. 1471) names to associate with the `Listener`. Specify only policies that are compatible with a `Listener`. For more information, see `DescribeLoadBalancerPolicyTypes` in the *Elastic Load Balancing API Reference version 2012-06-01*.

Note

By default, Elastic Load Balancing associates the latest predefined policy with your load balancer. When a new predefined policy is added, we recommend that you update your load balancer to use the new predefined policy. Alternatively, you can select a different predefined security policy or create a custom policy. To create a security policy, use the `Policies` property of the AWS::ElasticLoadBalancing::LoadBalancer (p. 1452) resource.

Required: No

Type: List of String values

`Protocol`

Specifies the load balancer transport protocol to use for routing: HTTP, HTTPS, TCP or SSL. You can't modify this property during the life of the load balancer.

Required: Yes

Type: String

`SSLCertificateId`

The ARN of the SSL certificate to use. For more information about SSL certificates, see Managing Server Certificates in the *AWS Identity and Access Management User Guide*.

Required: No

Type: String

ElasticLoadBalancing Policy

The ElasticLoadBalancing policy type is an embedded property of the AWS::ElasticLoadBalancing::LoadBalancer (p. 1452) resource. You associate policies with a listener (p. 1469) by referencing a policy's name in the listener's `PolicyNames` property.

Syntax

JSON

```
{
  "Attributes (p. 1471)" : [ { "Name" : String, "Value" : String }, ... ],
  "InstancePorts (p. 1471)" : [ String, ... ],
  "LoadBalancerPorts (p. 1471)" : [ String, ... ],
  "PolicyName (p. 1472)" : String,
  "PolicyType (p. 1472)" : String
}
```

YAML

```
Attributes (p. 1471):
  -
    "Name" : String
    "Value" : String
InstancePorts (p. 1471):
  - String
LoadBalancerPorts (p. 1471):
  - String
PolicyName (p. 1472): String
PolicyType (p. 1472): String
```

Properties

`Attributes`

A list of arbitrary attributes for this policy. If you don't need to specify any policy attributes, specify an empty list (`[ ]`).

Required: Yes

Type: List of JSON name-value pairs.

`InstancePorts`

A list of instance ports for the policy. These are the ports associated with the back-end server.

Required: No

Type: List of String values

`LoadBalancerPorts`

A list of external load balancer ports for the policy.

Required: Only for some policies. For more information, see the *Elastic Load Balancing Developer Guide*.

Type: List of String values

`PolicyName`

A name for this policy that is unique to the load balancer.

Required: Yes

Type: String

`PolicyType`

The name of the policy type for this policy. This must be one of the types reported by the Elastic Load Balancing DescribeLoadBalancerPolicyTypes action.

Required: Yes

Type: String

Examples

This example shows a snippet of the policies section of an elastic load balancer listener.

```
"Policies" : [
   {
      "PolicyName" : "MySSLNegotiationPolicy",
      "PolicyType" : "SSLNegotiationPolicyType",
      "Attributes" : [
         { "Name" : "Protocol-TLSv1", "Value" : "true" },
         { "Name" : "Protocol-SSLv3", "Value" : "false" },
         { "Name" : "DHE-RSA-AES256-SHA", "Value" : "true" } ]
   }, {
      "PolicyName" : "MyAppCookieStickinessPolicy",
      "PolicyType" : "AppCookieStickinessPolicyType",
      "Attributes" : [
         { "Name" : "CookieName", "Value" : "MyCookie"} ]
   }, {
      "PolicyName" : "MyPublicKeyPolicy",
      "PolicyType" : "PublicKeyPolicyType",
      "Attributes" : [ {
         "Name" : "PublicKey",
         "Value" : { "Fn::Join" : [
            "\n", [
               "MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDh/51Aohx5VrpmlfGHZCzciMBa",
               "fkHve+MQYYJcxmNUKMdsWnz9WtVfKxxWUU7Cfor4lorYmENGCG8FWqCoLDMFs7pN",
               "yGEtpsrlKhzZWtgY1d7eGrUrBil03bI90E2KW0j4qAwGYAC8xixOkNClicojeEz4",
               "f4rr3sUf+ZBSsuMEuwIDAQAB" ]
         ] }
      } ]
   }, {
      "PolicyName" : "MyBackendServerAuthenticationPolicy",
      "PolicyType" : "BackendServerAuthenticationPolicyType",
      "Attributes" : [
         { "Name" : "PublicKeyPolicyName", "Value" : "MyPublicKeyPolicy" } ],
      "InstancePorts" : [ "8443" ]
   }
]
```

This example shows a snippet of the policies section of an elastic load balancer using proxy protocol.

```
"Policies" : [{
   "PolicyName" : "EnableProxyProtocol",
```

```
   "PolicyType" : "ProxyProtocolPolicyType",
   "Attributes" : [{
      "Name"  : "ProxyProtocol",
      "Value" : "true"
   }],
   "InstancePorts" : [{"Ref" : "WebServerPort"}]
}]
```

In the following snippet, the load balancer uses a predefined security policy. These predefined policies are provided by Elastic Load Balancing. For more information, see SSL Security Policies in the *User Guide for Classic Load Balancers*.

```
"Policies" : [{
   "PolicyName" : "ELBSecurityPolicyName",
   "PolicyType" : "SSLNegotiationPolicyType",
   "Attributes" : [{
      "Name"  : "Reference-Security-Policy",
      "Value" : "ELBSecurityPolicy-2014-10"
   }]
}]
```

Elastic Load Balancing V2 Resource Types Reference

This section contains reference information for all Elastic Load Balancing V2 resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::ElasticLoadBalancingV2::data-type-name
```

Topics

- AWS::ElasticLoadBalancingV2::Listener (p. 1473)
- AWS::ElasticLoadBalancingV2::ListenerCertificate (p. 1477)
- AWS::ElasticLoadBalancingV2::ListenerRule (p. 1480)
- AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484)
- AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491)

AWS::ElasticLoadBalancingV2::Listener

The `AWS::ElasticLoadBalancingV2::Listener` resource creates a listener for an Elastic Load Balancing Application or Network load balancer. The listener checks for connection requests and forwards them to one or more target groups. For more information, see Getting Started in the *Elastic Load Balancing User Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElasticLoadBalancingV2::Listener",
  "Properties" : {
    "Certificates" : [ Certificate (p. 1477) ],
    "DefaultActions" : [ Action (p. 1476), ... ],
    "LoadBalancerArn" : String,
    "Port" : Integer,
    "Protocol" : String,
    "SslPolicy" : String
  }
}
```

YAML

```
Type: AWS::ElasticLoadBalancingV2::Listener
Properties:
  Certificates:
    - Certificate (p. 1477)
  DefaultActions:
    - Action (p. 1476)
  LoadBalancerArn: String
  Port: Integer
  Protocol: String
  SslPolicy: String
```

Properties

`Certificates`

The SSL server certificate for the listener. With a certificate, you can encrypt traffic between the load balancer and the clients that initiate HTTPS sessions, and traffic between the load balancer and your targets.

This property represents the default certificate for the listener. You can specify only one certificate for the `AWS::ElasticLoadBalancingV2::Listener` resource.

Required: Conditional. If you specify `HTTPS` for the `Protocol` property, specify a certificate.

Type: List of Elastic Load Balancing Listener Certificate (p. 1477)

Update requires: No interruption (p. 120)

`DefaultActions`

The default actions that the listener takes when handling incoming requests.

Required: Yes

Type: List of Elastic Load Balancing Listener Action (p. 1476)

Update requires: No interruption (p. 120)

`LoadBalancerArn`

The Amazon Resource Name (ARN) of the load balancer to associate with the listener.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Port`

The port on which the listener listens for requests.

For valid values, see the `Port` parameter for the CreateListener action in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

`Protocol`

The protocol that clients must use to send requests to the listener.

For valid values, see the `Protocol` parameter for the CreateListener action in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`SslPolicy`

The security policy that defines the ciphers and protocols that the load balancer supports.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the listener's ARN, such as `arn:aws:elasticloadbalancing:us-west-2:123456789012:listener/app/my-load-balancer/50dc6c495c0c9188/f2f7dc8efc522ab2`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a listener for the `myLoadBalancer` resource. The listener's default action is to forward requests to the `myTargetGroup` target group.

JSON

```
"Listener": {
  "Type": "AWS::ElasticLoadBalancingV2::Listener",
  "Properties": {
    "DefaultActions": [{
      "Type": "forward",
      "TargetGroupArn": { "Ref": "myTargetGroup" }
    }],
    "LoadBalancerArn": { "Ref": "myLoadBalancer" },
    "Port": "8000",
```

```
    "Protocol": "HTTP"
  }
}
```

YAML

```
Listener:
  Type: AWS::ElasticLoadBalancingV2::Listener
  Properties:
    DefaultActions:
    - Type: forward
      TargetGroupArn:
        Ref: myTargetGroup
    LoadBalancerArn:
      Ref: myLoadBalancer
    Port: '8000'
    Protocol: HTTP
```

Elastic Load Balancing Listener Action

The `Action` property type specifies the default actions that the Elastic Load Balancing listener takes when handling incoming requests.

The `DefaultActions` property of the AWS::ElasticLoadBalancingV2::Listener (p. 1473) resource contains a list of `Action` property types.

Syntax

JSON

```
{
  "TargetGroupArn" : String,
  "Type" : String
}
```

YAML

```
TargetGroupArn: String
Type: String
```

Properties

`TargetGroupArn`

The Amazon Resource Name (ARN) of the target group to which Elastic Load Balancing routes the traffic.

Required: Yes

Type: String

`Type`

The type of action.

Valid values: `forward`

Required: Yes

Type: String

Elastic Load Balancing Listener Certificate

The `Certificate` property type specifies the default SSL server certificate that Elastic Load Balancing will deploy on an listener. For more information, see Create an HTTPS Listener for Your Application Load Balancer in the *Application Load Balancers Guide*.

The `Certificates` property of the AWS::ElasticLoadBalancingV2::Listener (p. 1473) resource contains a list of one `Certificate` property type.

Syntax

JSON

```
{
  "CertificateArn" : String
}
```

YAML

```
CertificateArn: String
```

Properties

`CertificateArn`

The Amazon Resource Name (ARN) of the certificate to associate with the listener.

Required: No

Type: String

AWS::ElasticLoadBalancingV2::ListenerCertificate

The `AWS::ElasticLoadBalancingV2::ListenerCertificate` resource specifies certificates for an Elastic Load Balancing secure listener. For more information, see Getting Started in the *Elastic Load Balancing User Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElasticLoadBalancingV2::ListenerCertificate",
  "Properties" : {
    "Certificates" : [ Certificate (p. 1479), ... ]
    "ListenerArn" : String
  }
}
```

YAML

```
Type: AWS::ElasticLoadBalancingV2::ListenerCertificate
Properties:
  Certificates:
    - Certificate (p. 1479)
```

```
  ListenerArn: String
```

Properties

`Certificates`

Certificates specified for the listener. Duplicates not allowed.

Required: Yes

Type: List of Certificate (p. 1479)

Update requires: Replacement (p. 121)

`ListenerArn`

The Amazon Resource Name (ARN) of the listener.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Example

The following example specifies a listener certificate, containing a single certificate, for a load balancer listener.

JSON

```
{
    "Parameters": {
        "CertificateArn1": {
            "Type": "String"
        },
        "CertificateArn2": {
            "Type": "String"
        },
        "LoadBalancerArn": {
            "Type": "String"
        },
        "TargetGroupArn": {
            "Type": "String"
        }
    },
    "Resources": {
        "ListenerCertificate": {
            "Type": "AWS::ElasticLoadBalancingV2::ListenerCertificate",
            "Properties": {
                "Certificates": [
                    {
                        "CertificateArn": {
                            "Ref": "CertificateArn1"
                        }
                    }
                ],
                "ListenerArn": {
                    "Ref": "Listener"
                }
            }
        },
```

```
        "Listener": {
            "Type": "AWS::ElasticLoadBalancingV2::Listener",
            "Properties": {
                "DefaultActions": [
                    {
                        "Type": "forward",
                        "TargetGroupArn": {
                            "Ref": "TargetGroupArn"
                        }
                    }
                ],
                "LoadBalancerArn": {
                    "Ref": "LoadBalancerArn"
                },
                "Port": "8000",
                "Protocol": "HTTPS",
                "Certificates": [
                    {
                        "CertificateArn": {
                            "Ref": "CertificateArn2"
                        }
                    }
                ]
            }
        }
    }
}
```

YAML

```
Parameters:
  CertificateArn1:
    Type: String
  CertificateArn2:
    Type: String
  LoadBalancerArn:
    Type: String
  TargetGroupArn:
    Type: String
Resources:
  ListenerCertificate:
    Type: AWS::ElasticLoadBalancingV2::ListenerCertificate
    Properties:
      Certificates:
        - CertificateArn: !Ref CertificateArn1
      ListenerArn: !Ref Listener
  Listener:
    Type: AWS::ElasticLoadBalancingV2::Listener
    Properties:
      DefaultActions:
        - Type: forward
          TargetGroupArn: !Ref TargetGroupArn
      LoadBalancerArn: !Ref LoadBalancerArn
      Port: '8000'
      Protocol: HTTPS
      Certificates:
        - CertificateArn: !Ref CertificateArn2
```

Elastic Load Balancing ListenerCertificate Certificate

The `Certificate` property type specifies a certificate for an Elastic Load Balancing listener certificate.

`Certificate` is a property of the AWS::ElasticLoadBalancingV2::ListenerCertificate (p. 1477) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "CertificateArn" : String
}
```

YAML

```
CertificateArn: String
```

Properties

`CertificateArn`

The Amazon Resource Name (ARN) of the certificate.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS::ElasticLoadBalancingV2::ListenerRule

The `AWS::ElasticLoadBalancingV2::ListenerRule` resource defines which requests an Elastic Load Balancing listener takes action on and the action that it takes. For more information, see Getting Started in the *Elastic Load Balancing User Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElasticLoadBalancingV2::ListenerRule",
  "Properties" : {
    "Actions" : [ Actions (p. 1482), ... ],
    "Conditions" : [ Conditions (p. 1483), ... ],
    "ListenerArn" : String,
    "Priority" : Integer
  }
}
```

YAML

```
Type: AWS::ElasticLoadBalancingV2::ListenerRule
Properties:
  Actions:
    - Actions (p. 1482)
  Conditions:
    - Conditions (p. 1483)
  ListenerArn: String
```

```
  Priority: Integer
```

Properties

`Actions`

The action that the listener takes when a request meets the specified condition.

Required: Yes

Type: List of Elastic Load Balancing ListenerRule Actions (p. 1482)

Update requires: No interruption (p. 120)

`Conditions`

The conditions under which a rule takes effect.

Required: Yes

Type: List of Elastic Load Balancing ListenerRule Conditions (p. 1483)

Update requires: No interruption (p. 120)

`ListenerArn`

The Amazon Resource Name (ARN) of the listener that the rule applies to.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Priority`

The priority for the rule. Elastic Load Balancing evaluates rules in priority order, from the lowest value to the highest value. If a request satisfies a rule, Elastic Load Balancing ignores all subsequent rules.

> **Note**
> A listener can have only one rule with a given priority.

For valid values, see the `Priority` parameter for the CreateRule action in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the rule's ARN, such as `arn:aws:elasticloadbalancing:us-west-2:123456789012:listener-rule/app/my-load-balancer/50dc6c495c0c9188/f2f7dc8efc522ab2/9683b2d02a6cabee`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a rule that forwards requests to the `TargetGroup` target group if the request URL contains the `/img/*` pattern.

JSON

```
"ListenerRule": {
  "Type": "AWS::ElasticLoadBalancingV2::ListenerRule",
  "Properties": {
    "Actions": [{
      "Type": "forward",
      "TargetGroupArn": { "Ref": "TargetGroup" }
    }],
    "Conditions": [{
      "Field": "path-pattern",
      "Values": [ "/img/*" ]
    }],
    "ListenerArn": { "Ref": "Listener" },
    "Priority": 1
  }
}
```

YAML

```
ListenerRule:
  Type: AWS::ElasticLoadBalancingV2::ListenerRule
  Properties:
    Actions:
    - Type: forward
      TargetGroupArn:
        Ref: TargetGroup
    Conditions:
    - Field: path-pattern
      Values:
      - "/img/*"
    ListenerArn:
      Ref: Listener
    Priority: 1
```

Elastic Load Balancing ListenerRule Actions

`Actions` is a property of the AWS::ElasticLoadBalancingV2::ListenerRule (p. 1480) resource that specifies the actions an Elastic Load Balancing listener takes when an incoming request meets a listener rule's condition.

Syntax

JSON

```
{
  "TargetGroupArn" : String,
  "Type" : String
}
```

YAML

```
TargetGroupArn: String
Type: String
```

Properties

`TargetGroupArn`

The Amazon Resource Name (ARN) of the target group to which Elastic Load Balancing routes the traffic.

Required: Yes

Type: String

`Type`

The type of action.

Valid values: `forward`

Required: Yes

Type: String

Elastic Load Balancing ListenerRule Conditions

`Conditions` is a property of the AWS::ElasticLoadBalancingV2::ListenerRule (p. 1480) resource that specifies the conditions when an Elastic Load Balancing listener rule takes effect.

Syntax

JSON

```
{
  "Field" : String,
  "Values" : [ String, ... ]
}
```

YAML

```
Field: String
Values:
  - String
```

Properties

`Field`

The name of the condition that you want to define, such as `path-pattern` (which forwards requests based on the URL of the request).

For valid values, see the `Field` contents for the RuleCondition data type in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: No

Type: String

`Values`

The value for the field that you specified in the `Field` property.

Required: No

Type: List of String values

AWS::ElasticLoadBalancingV2::LoadBalancer

The `AWS::ElasticLoadBalancingV2::LoadBalancer` resource creates an Elastic Load Balancing Application or Network Load Balancer. For more information, see Getting Started in the *Elastic Load Balancing User Guide*.

> **Note**
> AWS CloudFormation does not automatically create tags (key–value pairs) for an Elastic Load Balancing load balancer. You must use the `Tags` (p. 1486) property to create tags to associate with the load balancer.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElasticLoadBalancingV2::LoadBalancer",
  "Properties" : {
    "IpAddressType" : String,
    "LoadBalancerAttributes" : [ LoadBalancerAttributes (p. 1489), ... ],
    "Name" : String,
    "Scheme" : String,
    "SecurityGroups" : [ String, ... ],
    "SubnetMappings" : [ SubnetMapping (p. 1490), ... ],
    "Subnets" : [ String, ... ],
    "Tags" : [ Resource Tag, ... ],
    "Type" : String
  }
}
```

YAML

```
Type: AWS::ElasticLoadBalancingV2::LoadBalancer
Properties:
  IpAddressType: String
  LoadBalancerAttributes:
    - LoadBalancerAttributes (p. 1489)
  Name: String
  Scheme: String
  SecurityGroups:
    - String
  SubnetMappings:
    - SubnetMapping (p. 1490)
  Subnets:
    - String
  Tags:
    - Resource Tag
  Type: String
```

Properties

For more information and valid parameter values, see the `CreateLoadBalancer` action in the Elastic Load Balancing API Reference version 2015-12-01.

`IpAddressType`

[Application Load Balancers] The type of IP addresses that are used by the load balancer's subnets, such as `ipv4` (for IPv4 addresses) or `dualstack` (for IPv4 and IPv6 addresses). For valid values, see

the `IpAddressType` parameter for the `CreateLoadBalancer` action in the *Elastic Load Balancing API Reference version 2015-12-01*. The default value is `ipv4`.

Required: No

Type: String

Update requires: No interruption (p. 120)

Note
If `Scheme` is `internal`, then `IpAddressType` must be `ipv4`.

`LoadBalancerAttributes`

Specifies the load balancer configuration.

Required: No

Type: A list of Elastic Load Balancing LoadBalancer LoadBalancerAttributes (p. 1489)

Update requires: No interruption (p. 120)

`Name`

Specifies a name for the load balancer. This name must be unique within your AWS account and can have a maximum of 32 alphanumeric characters and hyphens. A name can't begin or end with a hyphen.

Important
If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Scheme`

Specifies whether the load balancer is internal or Internet-facing. Valid values are `internet-facing` and `internal`. The default is `internet-facing`.

The nodes of an Internet-facing load balancer have public IP addresses. The DNS name of an Internet-facing load balancer is publicly resolvable to the public IP addresses of the nodes. Therefore, Internet-facing load balancers can route requests from clients over the Internet.

The nodes of an internal load balancer have only private IP addresses. The DNS name of an internal load balancer is publicly resolvable to the private IP addresses of the nodes. Therefore, internal load balancers can only route requests from clients with access to the VPC for the load balancer.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SecurityGroups`

[Application Load Balancers] Specifies a list of the IDs of the security groups to assign to the load balancer.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SubnetMappings`

The subnets to attach to the load balancer, specified as a list of `SubnetMapping` property types. You can specify only one subnet per Availability Zone. You must specify either subnets or subnet mappings.

[Application Load Balancers] You must specify subnets from at least two Availability Zones. You cannot specify your own Elastic IP addresses.

[Network Load Balancers] You can specify subnets from one or more Availability Zones. You can specify one Elastic IP address per subnet.

Required: No

Type: List of Elastic Load Balancing LoadBalancer SubnetMapping (p. 1490)

Update requires: Replacement (p. 121)

`Subnets`

The subnets to attach to the load balancer, specified as a list of subnet IDs. You can specify only one subnet per Availability Zone. You must specify either subnets or subnet mappings.

[Application Load Balancers] You must specify subnets from at least two Availability Zones.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this load balancer. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`Type`

Specifies the type of load balancer to create. Valid values are `application` and `network`.The default is `application`.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the ARN of the load balancer, for example:

```
arn:aws:elasticloadbalancing:us-west-2:123456789012:loadbalancer/app/my-internal-load-
balancer/50dc6c495c0c9188
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for the following attributes.

`CanonicalHostedZoneID`

The ID of the Amazon Route 53 hosted zone associated with the load balancer, for example `Z2P70J7EXAMPLE`.

`DNSName`

The DNS name for the load balancer, for example `my-load-balancer-424835706.us-west-2.elb.amazonaws.com`.

`LoadBalancerFullName`

The full name of the load balancer, for example `app/my-load-balancer/50dc6c495c0c9188`.

`LoadBalancerName`

The name of the load balancer, for example `my-load-balancer`.

`SecurityGroups`

The IDs of the security groups for the load balancer, for example `sg-123456a`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Load balancer with idle timeout period specified

The following example creates an internal load balancer with an idle timeout period of `50` seconds.

JSON

```
"loadBalancer" : {
  "Type": "AWS::ElasticLoadBalancingV2::LoadBalancer",
  "Properties": {
    "Scheme" : "internal",
    "Subnets" : [ {"Ref": "SubnetAZ1"}, {"Ref" : "SubnetAZ2"}],
    "LoadBalancerAttributes" : [
      { "Key" : "idle_timeout.timeout_seconds", "Value" : "50" }
    ],
    "SecurityGroups": [{"Ref": "SecurityGroup1"}, {"Ref" : "SecurityGroup2"}],
    "Tags" : [
      { "Key" : "key", "Value" : "value" },
      { "Key" : "key2", "Value" : "value2" }
    ]
  }
}
```

YAML

```
loadBalancer:
  Type: AWS::ElasticLoadBalancingV2::LoadBalancer
  Properties:
    Scheme: internal
```

```
    Subnets:
    - Ref: SubnetAZ1
    - Ref: SubnetAZ2
    LoadBalancerAttributes:
    - Key: idle_timeout.timeout_seconds
      Value: '50'
    SecurityGroups:
    - Ref: SecurityGroup1
    - Ref: SecurityGroup2
    Tags:
    - Key: key
      Value: value
    - Key: key2
      Value: value2
```

Load balancer with subnets

The following example creates a load balancer with two mapped subnets.

JSON

```
{
    "Parameters": {
        "FirstSubnet": {
            "Type": "String"
        },
        "SecondSubnet": {
            "Type": "String"
        },
        "ELBType": {
            "Type": "String"
        },
        "ELBIpAddressType": {
            "Type": "String"
        }
    },
    "Resources": {
        "loadBalancer": {
            "Type": "AWS::ElasticLoadBalancingV2::LoadBalancer",
            "Properties": {
                "SubnetMappings": [
                    {
                        "AllocationId": {
                            "Fn::GetAtt": [
                                "FirstEIP",
                                "AllocationId"
                            ]
                        },
                        "SubnetId": {
                            "Ref": "FirstSubnet"
                        }
                    },
                    {
                        "AllocationId": {
                            "Fn::GetAtt": [
                                "SecondEIP",
                                "AllocationId"
                            ]
                        },
                        "SubnetId": {
                            "Ref": "SecondSubnet"
                        }
                    }
                ],
```

```
                "Type": {
                    "Ref": "ELBType"
                },
                "IpAddressType": {
                    "Ref": "ELBIpAddressType"
                }
            }
        },
        "FirstEIP": {
            "Type": "AWS::EC2::EIP",
            "Properties": {
                "Domain": "vpc"
            }
        },
        "SecondEIP": {
            "Type": "AWS::EC2::EIP",
            "Properties": {
                "Domain": "vpc"
            }
        }
    }
}
```

YAML

```
Parameters:
  FirstSubnet:
    Type: String
  SecondSubnet:
    Type: String
  ELBType:
    Type: String
  ELBIpAddressType:
    Type: String
Resources:
  loadBalancer:
    Type: AWS::ElasticLoadBalancingV2::LoadBalancer
    Properties:
      SubnetMappings:
        - AllocationId: !GetAtt
            - FirstEIP
            - AllocationId
          SubnetId: !Ref FirstSubnet
        - AllocationId: !GetAtt
            - SecondEIP
            - AllocationId
          SubnetId: !Ref SecondSubnet
      Type: !Ref ELBType
      IpAddressType: !Ref ELBIpAddressType
  FirstEIP:
    Type: AWS::EC2::EIP
    Properties:
      Domain: vpc
  SecondEIP:
    Type: AWS::EC2::EIP
    Properties:
      Domain: vpc
```

Elastic Load Balancing LoadBalancer LoadBalancerAttributes

`LoadBalancerAttributes` is a property of the AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484) resource that configures settings for an Elastic Load Balancing Application load balancer. For more information, see Load Balancer Attributes in the *Application Load Balancers Guide*.

Syntax

JSON

```
{
  "Key" : String,
  "Value" : String
}
```

YAML

```
Key: String
Value: String
```

Properties

`Key`

The name of an attribute that you want to configure. For the list of attributes that you can configure, see the `Key` contents for the LoadBalancerAttribute data type in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: No

Type: String

`Value`

A value for the attribute.

Required: No

Type: String

Elastic Load Balancing LoadBalancer SubnetMapping

The `SubnetMapping` property type specifies the ID of a subnet to attach to an Elastic Load Balancing Application or Network Load Balancer.

`SubnetMappings` is a property of the AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484) resource.

Syntax

JSON

```
{
  "SubnetId" : String,
  "AllocationId" : String
}
```

YAML

```
SubnetId: String
AllocationId: String
```

Properties

`SubnetId`

The ID of the subnet.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`AllocationId`

[Network Load Balancer] The ID that represents the allocation of the Elastic IP address.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

AWS::ElasticLoadBalancingV2::TargetGroup

The `AWS::ElasticLoadBalancingV2::TargetGroup` resource creates an Elastic Load Balancing target group that routes requests to one or more registered targets, such as EC2 instances. For more information, see Getting Started in the *Elastic Load Balancing User Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ElasticLoadBalancingV2::TargetGroup",
  "Properties" : {
    "HealthCheckIntervalSeconds" : Integer,
    "HealthCheckPath" : String,
    "HealthCheckPort" : String,
    "HealthCheckProtocol" : String,
    "HealthCheckTimeoutSeconds" : Integer,
    "HealthyThresholdCount" : Integer,
    "Matcher" : Matcher (p. 1498),
    "Name" : String,
    "Port" : Integer,
    "Protocol" : String,
    "Tags" : [ Resource Tag (p. 2258), ... ],
    "TargetGroupAttributes" : [ TargetGroupAttributes (p. 1500), ... ],
    "Targets" : [ TargetDescription (p. 1499), ... ],
    "TargetType" : String,
    "UnhealthyThresholdCount" : Integer,
    "VpcId" : String
  }
}
```

YAML

```
Type: AWS::ElasticLoadBalancingV2::TargetGroup
Properties:
  HealthCheckIntervalSeconds: Integer
  HealthCheckPath: String
  HealthCheckPort: String
  HealthCheckProtocol: String
  HealthCheckTimeoutSeconds: Integer
  HealthyThresholdCount: Integer
  Matcher: Matcher (p. 1498)
  Name: String
```

```
  Port: Integer
  Protocol: String
  Tags:
    - Resource Tag (p. 2258)
  TargetGroupAttributes:
    - TargetGroupAttributes (p. 1500)
  Targets:
    - TargetDescription (p. 1499)
  TargetType: String
  UnhealthyThresholdCount: Integer
  VpcId: String
```

Properties

`HealthCheckIntervalSeconds`

The approximate number of seconds between health checks for an individual target.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`HealthCheckPath`

The ping path destination where Elastic Load Balancing sends health check requests.

Required: No

Type: String

Update requires: No interruption (p. 120)

`HealthCheckPort`

The port that the load balancer uses when performing health checks on the targets.

For valid and default values, see the `HealthCheckPort` parameter for the CreateTargetGroup action in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`HealthCheckProtocol`

The protocol that the load balancer uses when performing health checks on the targets, such as `HTTP` or `HTTPS`.

For valid and default values, see the `HealthCheckProtocol` parameter for the CreateTargetGroup action in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`HealthCheckTimeoutSeconds`

The number of seconds to wait for a response before considering that a health check has failed.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`HealthyThresholdCount`

The number of consecutive successful health checks that are required before an unhealthy target is considered healthy.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Matcher`

The HTTP codes that a healthy target uses when responding to a health check. If you specify TCP for the `Protocol` property, you must specify the range 200-399 for the `Matcher` property.

For more information about specifying this property, see Matcher in the Elastic Load Balancing API Reference version 2015-12-01.

Required: No

Type: Elastic Load Balancing TargetGroup Matcher (p. 1498)

Update requires: No interruption (p. 120)

`Name`

A name for the target group.

> **Important**
> This name must be unique per account, per region.
> The target group name should be shorter than 32 characters because AWS CloudFormation uses the target group name to create the name of the load balancer.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Port`

The port on which the targets receive traffic.

Required: Yes

Type: Integer

Update requires: Replacement (p. 121)

`Protocol`

The protocol to use for routing traffic to the targets.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) for the target group. Use tags to help manage resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120).

`TargetGroupAttributes`

Target group configurations.

Required: No

Type: List of Elastic Load Balancing TargetGroup TargetGroupAttributes (p. 1500)

Update requires: No interruption (p. 120)

`Targets`

The targets to add to this target group.

Required: No

Type: List of Elastic Load Balancing TargetGroup TargetDescription (p. 1499)

Update requires: No interruption (p. 120)

`TargetType`

The registration type of the targets in this target group. Valid values are `instance` and `ip`. The default is `instance`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`UnhealthyThresholdCount`

The number of consecutive failed health checks that are required before a target is considered unhealthy.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`VpcId`

The ID of the VPC in which your targets are located.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the target group's Amazon Resource Name (ARN), such as `arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/my-targets/73e2d6bc24d8a067`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`LoadBalancerArns`

A list of Amazon Resource Names (ARNs) of the load balancers that route traffic to this target group, such as `[ "arn:aws:elasticloadbalancing:us-west-2:123456789012:loadbalancer/app/my-load-balancer/50dc6c495c0c9188" ]`.

`TargetGroupFullName`

The full name of the target group, such as `targetgroup/my-target-group/cbf133c568e0d028`.

`TargetGroupName`

The name of the target group, such as `my-target-group`. This is the value of the target group's `Name` property.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Create a Target Group with EC2 Instances as Targets

The following examples creates a target group that includes the `Instance1` and `Instance2` EC2 instances as targets. The instances must respond with a `200` status code to pass health check requests.

JSON

```
"TargetGroup" : {
  "Type" : "AWS::ElasticLoadBalancingV2::TargetGroup",
  "Properties" : {
    "HealthCheckIntervalSeconds": 30,
    "HealthCheckProtocol": "HTTPS",
    "HealthCheckTimeoutSeconds": 10,
    "HealthyThresholdCount": 4,
    "Matcher" : {
      "HttpCode" : "200"
    },
    "Name": "MyTargets",
    "Port": 10,
    "Protocol": "HTTPS",
    "TargetGroupAttributes": [{
      "Key": "deregistration_delay.timeout_seconds",
      "Value": "20"
    }],
    "Targets": [
      { "Id": {"Ref" : "Instance1"}, "Port": 80 },
      { "Id": {"Ref" : "Instance2"}, "Port": 80 }
    ],
    "UnhealthyThresholdCount": 3,
    "VpcId": {"Ref" : "VPC"},
    "Tags" : [
      { "Key" : "key", "Value" : "value" },
      { "Key" : "key2", "Value" : "value2" }
    ]
  }
}
```

YAML

```
TargetGroup:
  Type: AWS::ElasticLoadBalancingV2::TargetGroup
  Properties:
    HealthCheckIntervalSeconds: 30
    HealthCheckProtocol: HTTPS
    HealthCheckTimeoutSeconds: 10
    HealthyThresholdCount: 4
    Matcher:
      HttpCode: '200'
    Name: MyTargets
    Port: 10
    Protocol: HTTPS
    TargetGroupAttributes:
    - Key: deregistration_delay.timeout_seconds
      Value: '20'
    Targets:
    - Id:
        Ref: Instance1
      Port: 80
    - Id:
        Ref: Instance2
      Port: 80
    UnhealthyThresholdCount: 3
    VpcId:
      Ref: VPC
    Tags:
    - Key: key
      Value: value
    - Key: key2
      Value: value2
```

Relate an Elastic Load Balancing Load Balancer to an Elastic Load Balancing Target Group

The following example creates an Elastic Load Balancing listener, associates it with a target group and a load balancer, and sets a target group attribute.

JSON

```
"ALBListener" : {
  "Type" : "AWS::ElasticLoadBalancingV2::Listener",
  "Properties" : {
    "DefaultActions" : [{
      "Type" : "forward",
      "TargetGroupArn" : { "Ref" : "ALBTargetGroup" }
    }],
    "LoadBalancerArn" : { "Ref" : "ApplicationLoadBalancer" },
    "Port" : "80",
    "Protocol" : "HTTP"
  }
},
"ApplicationLoadBalancer" : {
  "Type" : "AWS::ElasticLoadBalancingV2::LoadBalancer",
  "Properties" : {
    "Scheme" : "internet-facing",
    "Subnets" : [ {"Ref" : "PublicSubnetAz1"}, {"Ref" : "PublicSubnetAz2"}],
    "SecurityGroups" : [{"Ref": "ALBSecurityGroup"}]
  }
},
"ALBTargetGroup" : {
  "Type" : "AWS::ElasticLoadBalancingV2::TargetGroup",
  "Properties" : {
```

```
    "HealthCheckIntervalSeconds" : 60,
    "UnhealthyThresholdCount" : 10,
    "HealthCheckPath" : "/",
    "Name" : "MyTargetGroup",
    "Port" : 80,
    "Protocol" : "HTTP",
    "VpcId" : { "Ref": "MyVpc" }
    "TargetGroupAttributes" : [
      {
        "Key" : deregistration_delay.timeout_seconds,
        "Value" : 60
      }
    ]
  }
}
```

YAML

```
ALBListener:
  Type: AWS::ElasticLoadBalancingV2::Listener
  Properties:
    DefaultActions:
      - Type: forward
        TargetGroupArn:
          Ref: ALBTargetGroup
    LoadBalancerArn:
        Ref: ApplicationLoadBalancer
    Port: 80
    Protocol: HTTP
ApplicationLoadBalancer:
  Type: AWS::ElasticLoadBalancingV2::LoadBalancer
  Properties:
    Scheme: internet-facing
    Subnets:
      Ref: PublicSubnetAz1
      Ref: PublicSubnetAz2
    SecurityGroups:
      Ref: ALBSecurityGroup
ALBTargetGroup:
  Type: AWS::ElasticLoadBalancingV2::TargetGroup
  Properties:
    HealthCheckIntervalSeconds: 60
    UnhealthyThresholdCount: 10
    HealthCheckPath: /
    Name: MyTargetGroup
    Port: 80
    Protocol: HTTP
    VpcId:
      Ref: MyVpc
    TargetGroupAttributes:
      - Key: deregistration_delay.timeout_seconds
        Value: 60
```

Specify the Elastic Load Balancing Target Group type

The following example specifies the target group type as `instance`.

JSON

```
{
    "Parameters": {
        "CidrBlockForVPC": {
            "Type": "String"
```

```
        }
    },
    "Resources": {
        "VPC": {
            "Type": "AWS::EC2::VPC",
            "Properties": {
                "CidrBlock": {
                    "Ref": "CidrBlockForVPC"
                }
            }
        },
        "TargetGroup": {
            "Type": "AWS::ElasticLoadBalancingV2::TargetGroup",
            "Properties": {
                "Port": 1000,
                "Protocol": "HTTPS",
                "TargetType": "instance",
                "VpcId": {
                    "Ref": "VPC"
                }
            }
        }
    }
}
```

YAML

```
Parameters:
  CidrBlockForVPC:
    Type: String
Resources:
  VPC:
    Type: AWS::EC2::VPC
    Properties:
      CidrBlock: !Ref CidrBlockForVPC
  TargetGroup:
    Type: AWS::ElasticLoadBalancingV2::TargetGroup
    Properties:
      Port: 1000
      Protocol: HTTPS
      TargetType: instance
      VpcId: !Ref VPC
```

Elastic Load Balancing TargetGroup Matcher

`Matcher` is a property of the AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491) resource that specifies the HTTP codes that healthy targets must use when responding to an Elastic Load Balancing health check.

Syntax

JSON

```
{
  "HttpCode" : String
}
```

YAML

```
HttpCode: String
```

Properties

`HttpCode`

The HTTP codes that a healthy target must use when responding to a health check, such as `200,202` or `200-399`.

For valid and default values, see the `HttpCode` contents for the Matcher data type in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: No

Type: String

Elastic Load Balancing TargetGroup TargetDescription

`TargetDescription` is a property of the AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491) resource that specifies a target to add to an Elastic Load Balancing target group.

Syntax

JSON

```
{
  "AvailabilityZone" : String,
  "Id" : String,
  "Port" : Integer
}
```

YAML

```
AvailabilityZone: String
Id: String
Port: Integer
```

Properties

`AvailabilityZone`

The Availability Zone where the IP address is to be registered. For more information, see TargetDescription in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: No

Type: String

`Id`

The ID of the target, such as an EC2 instance ID. If the target type of the target group is `instance`, specify an instance ID. If the target type is `ip`, specify an IP address.

Required: Yes

Type: String

`Port`

The port number on which the target is listening for traffic.

Required: No

Type: Integer

Elastic Load Balancing TargetGroup TargetGroupAttributes

`TargetGroupAttributes` is a property of the AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491) resource that configures settings for an Elastic Load Balancing target group. For more information, see Target Group Attributes in the *Application Load Balancers Guide*.

Syntax

JSON

```
{
  "Key" : String,
  "Value" : String
}
```

YAML

```
Key: String
Value: String
```

Properties

`Key`

The name of the attribute that you want to configure. For the list of attributes that you can configure, see the `Key` contents for the TargetGroupAttribute data type in the *Elastic Load Balancing API Reference version 2015-12-01*.

Required: No

Type: String

`Value`

A value for the attribute.

Required: No

Type: String

Amazon EMR Resource Types Reference

This section contains reference information for all Amazon EMR resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::EMR::data-type-name
```

Topics

- AWS::EMR::Cluster (p. 1501)
- AWS::EMR::InstanceFleetConfig (p. 1541)

- AWS::EMR::InstanceGroupConfig (p. 1550)
- AWS::EMR::SecurityConfiguration (p. 1565)
- AWS::EMR::Step (p. 1568)

AWS::EMR::Cluster

The `AWS::EMR::Cluster` resource creates an Amazon EMR cluster. This cluster is a collection of EC2 instances that you can run big data frameworks on to process and analyze vast amounts of data. For more information, see Plan an Amazon EMR Cluster in the *Amazon EMR Management Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EMR::Cluster",
  "Properties" : {
    "AdditionalInfo" : JSON object,
    "Applications" : [ Applications, ... ],
    "AutoScalingRole" : String,
    "BootstrapActions" [ Bootstrap Actions, ... ],
    "Configurations" : [ Configurations, ... ],
    "CustomAmiId" : String,
    "EbsRootVolumeSize" : Integer,
    "Instances" : JobFlowInstancesConfig,
    "JobFlowRole" : String,
    "KerberosAttributes" : Amazon EMR Cluster KerberosAttributes,
    "LogUri" : String,
    "Name" : String,
    "ReleaseLabel" : String,
    "ScaleDownBehavior" : String,
    "SecurityConfiguration" : String,
    "ServiceRole" : String,
    "Tags" : [ Resource Tag, ... ],
    "VisibleToAllUsers" : Boolean
  }
}
```

YAML

```
Type: AWS::EMR::Cluster
Properties:
  AdditionalInfo: JSON object
  Applications:
    - Applications
  AutoScalingRole: String
  BootstrapActions:
    - Bootstrap Actions
  Configurations:
    - Configurations
  CustomAmiId: String
  EbsRootVolumeSize: Integer
  Instances:
    JobFlowInstancesConfig
  JobFlowRole: String
  KerberosAttributes" :
    Amazon EMR Cluster KerberosAttributes
  LogUri: String
```

```
  Name: String
  ReleaseLabel: String
  ScaleDownBehavior: String
  SecurityConfiguration: String
  ServiceRole: String
  Tags:
    - Resource Tag
  VisibleToAllUsers: Boolean
```

Properties

Note
For more information about the constraints and valid values of each property, see the Cluster data type in the *Amazon EMR API Reference*.

`AdditionalInfo`

(Intended for advanced uses only.) Additional features that you want to select. This is meta information about third-party applications that third-party vendors use for testing purposes.

Required: No

Type: JSON object

Update requires: Replacement (p. 121)

`Applications`

The software applications to deploy on the cluster, and the arguments that Amazon EMR passes to those applications.

Required: No

Type: List of Amazon EMR Cluster Application (p. 1518) property types

Update requires: Replacement (p. 121)

`AutoScalingRole`

An AWS Identity and Access Management (IAM) role for automatic scaling policies. The default role is `EMR_AutoScaling_DefaultRole`. The IAM role provides permissions that the automatic scaling feature requires to launch and terminate Amazon EC2 instances in an instance group.

Required: No

Type: String

Update requires: Replacement (p. 121)

`BootstrapActions`

A list of bootstrap actions that Amazon EMR runs before starting applications on the cluster.

Required: No

Type: List of Amazon EMR Cluster BootstrapActionConfig (p. 1520) property types

Update requires: Replacement (p. 121)

`Configurations`

The software configuration of the Amazon EMR cluster.

Required: No

Type: List of Amazon EMR Cluster Configurations (p. 1522) property types

Update requires: Replacement (p. 121)

`CustomAmiId`

A custom Amazon Linux AMI for the cluster (instead of an EMR-owned AMI). For more information, see Using a Custom AMI in the *Amazon EMR Management Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

Example: `"CustomAmiId" : "ami-7fb3bc69"`

`EbsRootVolumeSize`

The size, in GiB, of the EBS root device volume of the Linux AMI that's used for each EC2 instance.

Currently, AWS CloudFormation supports only Amazon EMR 4.0 and later software releases.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`Instances`

Configures the EC2 instances that run jobs in the Amazon EMR cluster.

Required: Yes

Type: Amazon EMR Cluster JobFlowInstancesConfig (p. 1529)

Update requires: Some interruptions (p. 121)

`JobFlowRole`

(Also called *instance profile* and *EC2 role*.) Accepts an instance profile that's associated with the role that you want to use. All EC2 instances in the cluster assume this role. For more information, see Create and Use IAM Roles for Amazon EMR in the *Amazon EMR Management Guide*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`KerberosAttributes`

Attributes for Kerberos configuration when Kerberos authentication is enabled using a security configuration.

Required: No

Type: Amazon EMR Cluster KerberosAttributes (p. 1532)

Update requires: Replacement (p. 121)

`LogUri`

An S3 bucket location that Amazon EMR writes logs files to from a job flow. If you don't specify a value, Amazon EMR doesn't write any log files.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Name`

A name for the Amazon EMR cluster.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ReleaseLabel`

The Amazon EMR software release label. A release is a set of software applications and components that you can install and configure on an Amazon EMR cluster. For more information, see About Amazon EMR Releases in the *Amazon EMR Release Guide*.

Currently, AWS CloudFormation supports only Amazon EMR 4.0 and later software releases.

Required: Conditional. If you specify the `Applications` property, you must specify this property.

Type: String

Update requires: Replacement (p. 121)

`ScaleDownBehavior`

Indicates how individual EC2 instances terminate when an automatic scale-in activity occurs or an instance group is resized. For more information, see Cluster in the Amazon EMR API Reference.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SecurityConfiguration`

The name of the security configuration that's applied to the cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ServiceRole`

The IAM role that Amazon EMR assumes to access AWS resources on your behalf. For more information, see Configure IAM Roles for Amazon EMR in the *Amazon EMR Management Guide*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) to help you identify the Amazon EMR cluster.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`VisibleToAllUsers`

Indicates whether the instances in the cluster are visible to all IAM users in the AWS account. If you specify `true`, all IAM users can view and (if they have permissions) manage the instances. If you specify `false`, only the IAM user that created the cluster can view and manage it.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

Default value: `false`

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the cluster ID, such as `j-1ABCD123AB1A`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`MasterPublicDNS`

The public DNS name of the master node (instance), such as `ec2-12-123-123-123.us-west-2.compute.amazonaws.com`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Create a Cluster with Two Core Nodes

The following example creates an Amazon EMR cluster with one master node and two core nodes. The specified IAM roles are the default roles provided by Amazon EMR. The example also assumes that the cluster is launched in an AWS Region with a default VPC and subnet. If you don't have these, use the `Ec2SubnetId` (p. 1529) property to specify the VPC and subnet for the cluster. Otherwise, AWS CloudFormation can't launch the cluster and returns the following status message: `ElasticMapReduce Cluster failed to stabilize`.

JSON

```
"TestCluster": {
  "Type": "AWS::EMR::Cluster",
  "Properties": {
    "Instances": {
      "MasterInstanceGroup": {
```

```
        "InstanceCount": 1,
        "InstanceType": "m3.xlarge",
        "Market": "ON_DEMAND",
        "Name": "Master"
      },
      "CoreInstanceGroup": {
        "InstanceCount": 2,
        "InstanceType": "m3.xlarge",
        "Market": "ON_DEMAND",
        "Name": "Core"
      },
      "TerminationProtected" : true
    },
    "Name": "TestCluster",
    "JobFlowRole": "EMR_EC2_DefaultRole",
    "ServiceRole": "EMR_DefaultRole",
    "ReleaseLabel": "emr-4.2.0",
    "Tags": [
      {
        "Key": "IsTest",
        "Value": "True"
      }
    ]
  }
}
```

YAML

```
TestCluster:
  Type: AWS::EMR::Cluster
  Properties:
    Instances:
      MasterInstanceGroup:
        InstanceCount: 1
        InstanceType: "m3.xlarge"
        Market: "ON_DEMAND"
        Name: "Master"
      CoreInstanceGroup:
        InstanceCount: 2
        InstanceType: "m3.xlarge"
        Market: "ON_DEMAND"
        Name: "Core"
      TerminationProtected: true
    Name: "TestCluster"

      -
        Key: "IsTest"
        Value: "True"
```

Create a Cluster with a Bootstrap Action

The following example creates an Amazon EMR cluster with a bootstrap action.

JSON

```
"TestCluster": {
  "Type": "AWS::EMR::Cluster",
  "Properties": {
    "BootstrapActions": [{
      "Name": "SomeBootStrapAction",
```

```
      "ScriptBootstrapAction": {
        "Path": "/path/to/s3"
      }
    }],
    "Instances": {
      "MasterInstanceGroup": {
        "InstanceCount": 1,
        "InstanceType": "m3.xlarge",
        "Market": "ON_DEMAND",
        "Name": "Master"
      },
      "CoreInstanceGroup": {
        "InstanceCount": 2,
        "InstanceType": "m3.xlarge",
        "Market": "ON_DEMAND",
        "Name": "Core"
      },
      "TerminationProtected": true
    },
    "Name": "TestCluster",
    "JobFlowRole": "EMR_EC2_DefaultRole",
    "ScaleDownBehavior": "TERMINATE_AT_TASK_COMPLETION",
    "ServiceRole": "EMR_DefaultRole",
    "ReleaseLabel": "emr-4.2.0",
    "Tags": [
      {
        "Key": "IsTest",
        "Value": "True"
      }
    ]
  }
}
```

YAML

```
TestCluster:
  Type: AWS::EMR::Cluster
  Properties:
    BootstrapActions:
      -
        Name: "SomeBootStrapAction"
        ScriptBootstrapAction:
          Path: "/path/to/s3"
    Instances:

Specify Root Volume Size

The following example template enables you to specify the size of the EBS root volume for an Amazon EMR cluster.

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Parameters" : {
    "InstanceType" : {
      "Type" : "String"
    },
    "ReleaseLabel" : {
      "Type" : "String"
    },
    "SubnetId" : {
      "Type" : "String"
    },
    "TerminationProtected" : {
      "Type" : "String",
      "Default" : "false"
    },
    "EbsRootVolumeSize" : {
      "Type" : "String"
    }
  },
  "Resources": {
    "cluster": {
      "Type": "AWS::EMR::Cluster",
      "Properties": {
        "EbsRootVolumeSize" : {"Ref" : "EbsRootVolumeSize"},
        "Instances": {

Amazon EMR Cluster Application

`Application` is a property of the AWS::EMR::Cluster (p. 1501) resource that adds an Amazon EMR (Amazon EMR) application bundle or third-party software to an Amazon EMR cluster.

Syntax

JSON

```
{
  "AdditionalInfo" : { String:String, ... },
  "Args" : [ String, ... ],
  "Name" : String,
  "Version" : String
}
```

YAML

```
AdditionalInfo:
```

```
  String: String
Args:
  - String
Name: String
Version: String
```

Properties

`AdditionalInfo`

Metadata about third-party applications that third-party vendors use for testing purposes.

Required: No

Type: String-to-string map

`Args`

Arguments that Amazon EMR passes to the application.

Required: No

Type: List of String values

`Name`

The name of the application to add to your cluster, such as `Hadoop` or `Hive`. For valid values, see the Applications parameter in the *Amazon EMR API Reference*.

Required: No

Type: String

`Version`

The version of the application.

Required: No

Type: String

Amazon EMR Cluster AutoScalingPolicy

`AutoScalingPolicy` is a subproperty of the Amazon EMR Cluster InstanceGroupConfig (p. 1525) property type that specifies the constraints and rules for an Auto Scaling group policy. For more information, see PutAutoScalingPolicy in the Amazon EMR API Reference.

Syntax

JSON

```
{
  "Constraints" : ScalingConstraints,
  "Rules" : ScalingRule
}
```

YAML

```
Constraints:
  - ScalingConstraints
```

```
Rules:
  - ScalingRule
```

Properties

`Constraints`

The upper and lower Amazon EC2 instance limits for an automatic scaling policy. Automatic scaling activity will not cause an instance group to grow above or below these limits.

Required: Yes

Type: Amazon EMR Cluster ScalingConstraints (p. 1536)

`Rules`

The scale-in and scale-out rules that comprise the automatic scaling policy.

Required: Yes

Type: Amazon EMR Cluster ScalingRule (p. 1537)

Amazon EMR Cluster BootstrapActionConfig

`BootstrapActionConfig` is a property of the AWS::EMR::Cluster (p. 1501) resource that specifies bootstrap actions that Amazon EMR (Amazon EMR) runs before it installs applications on the cluster nodes.

Syntax

JSON

```
{
  "Name" : String,
  "ScriptBootstrapAction" : ScriptBootstrapAction
}
```

YAML

```
Name: String
ScriptBootstrapAction: ScriptBootstrapAction
```

Properties

`Name`

The name of the bootstrap action to add to your cluster.

Required: Yes

Type: String

`ScriptBootstrapAction`

The script that the bootstrap action runs.

Required: Yes

Type: Amazon EMR Cluster ScriptBootstrapActionConfig (p. 1538)

Amazon EMR Cluster CloudWatchAlarmDefinition

`CloudWatchAlarmDefinition` is a subproperty of the Amazon EMR Cluster ScalingTrigger (p. 1538) property, which determines when to trigger an automatic scaling activity. Scaling activity begins when you satisfy the defined alarm conditions.

Syntax

JSON

```
{
  "ComparisonOperator" : String,
  "Dimensions" : [ MetricDimension, ... ],
  "EvaluationPeriods" : Integer,
  "MetricName" : String,
  "Namespace" : String,
  "Period" : Integer,
  "Statistic" : String,
  "Threshold" : Double,
  "Unit" : String
}
```

YAML

```
  ComparisonOperator: String
  Dimensions:
    - MetricDimension
  EvaluationPeriods: Integer
  MetricName: String
  Namespace: String
  Period: Integer
  Statistic: String
  Threshold: Double
  Unit: String
```

Properties

`ComparisonOperator`

Determines how the metric specified by `MetricName` is compared to the value specified by `Threshold`.

Valid values: `GREATER_THAN_OR_EQUAL`, `GREATER_THAN`, `LESS_THAN`, or `LESS_THAN_OR_EQUAL`.

Required: Yes

Type: String

`Dimensions`

A list of CloudWatch metric dimensions.

Required: No

Type: List of Amazon EMR Cluster MetricDimension (p. 1534)

`EvaluationPeriods`

The number of periods, expressed in seconds using `Period`, during which the alarm condition must exist before the alarm triggers automatic scaling activity. The default value is 1.

Required: No

Type: Integer

`MetricName`

The name of the CloudWatch metric that is watched to determine an alarm condition.

Required: Yes

Type: String

`Namespace`

The namespace for the CloudWatch metric. The default is `AWS/ElasticMapReduce`.

Required: No

Type: String

`Period`

The period, in seconds, over which the statistic is applied. EMR CloudWatch metrics are emitted every five minutes (300 seconds), so if an EMR CloudWatch metric is specified, specify 300.

Required: Yes

Type: Integer

`Statistic`

The statistic to apply to the metric associated with the alarm. The default is `AVERAGE`.

Valid values: `SAMPLE_COUNT`, `AVERAGE`, `SUM`, `MINIMUM`, or `MAXIMUM`.

Required: No

Type: String

`Threshold`

The value against which the specified statistic is compared.

Required: Yes

Type: Double

`Unit`

The unit of measure associated with the CloudWatch metric being watched. The value specified for Unit must correspond to the units specified in the CloudWatch metric.

For more information, see CloudWatchAlarmDefinition in the *Amazon Elastic MapReduce Documentation API Reference*.

Required: No

Type: String

Amazon EMR Cluster Configurations

`Configurations` is a property of the AWS::EMR::Cluster (p. 1501) resource that specifies the software configuration of an Amazon EMR (Amazon EMR) cluster. For example configurations, see Configuring Applications in the *Amazon EMR Release Guide*.

Syntax

JSON

```
{
  "Classification" : String,
  "ConfigurationProperties" : { String:String, ... },
  "Configurations" : [ Configuration, ... ]
}
```

YAML

```
Classification: String
ConfigurationProperties:
  String: String
Configurations:
  - Configuration
```

Properties

`Classification`

The name of an application-specific configuration file. For more information see, Configuring Applications in the *Amazon EMR Release Guide*.

Required: No

Type: String

`ConfigurationProperties`

The settings that you want to change in the application-specific configuration file. For more information see, Configuring Applications in the *Amazon EMR Release Guide*.

Required: No

Type: String-to-string map

`Configurations`

A list of configurations to apply to this configuration. You can nest configurations so that a single configuration can have its own configurations. In other words, you can configure a configuration. For more information see, Configuring Applications in the *Amazon EMR Release Guide*.

Required: No

Type: List of Amazon EMR Cluster Configurations (p. 1522)

Amazon EMR Cluster InstanceFleetConfig

The `InstanceFleetConfig` property type specifies a Spot instance fleet configuration for the cluster. For more information, see Configure Instance Fleets in the *Amazon EMR Management Guide*. `InstanceFleetConfig` is the property type for the `CoreInstanceFleet` and `MasterInstanceFleet` subproperties of the Amazon EMR Cluster JobFlowInstancesConfig (p. 1529) property type.

Note
The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

JSON

```
{
  "InstanceTypeConfigs" : [ InstanceTypeConfig (p. 1527) ],
  "LaunchSpecifications" : InstanceFleetProvisioningSpecifications (p. 1525),
  "Name" : String,
  "TargetOnDemandCapacity" : Integer,
  "TargetSpotCapacity" : Integer
}
```

YAML

```
InstanceTypeConfigs:
  - InstanceTypeConfig (p. 1527)
LaunchSpecifications:
  InstanceFleetProvisioningSpecifications (p. 1525)
Name: String
TargetOnDemandCapacity: Integer
TargetSpotCapacity: Integer
```

Properties

`InstanceTypeConfigs`

The instance type configurations that define the EC2 instances in the instance fleet. Duplicates not allowed.

Required: No

Type: List of Amazon EMR Cluster InstanceTypeConfig (p. 1527)

Update requires: Replacement (p. 121)

`LaunchSpecifications`

The launch specification for the instance fleet.

Required: No

Type: Amazon EMR Cluster InstanceFleetProvisioningSpecifications (p. 1525)

Update requires: Replacement (p. 121)

`Name`

The friendly name of the instance fleet. For constraints, see InstanceFleetConfig in the *Amazon EMR API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`TargetOnDemandCapacity`

The target capacity of On-Demand units for the instance fleet, which determines how many On-Demand instances to provision. For more information, see InstanceFleetConfig in the *Amazon EMR API Reference*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`TargetSpotCapacity`

The target capacity of Spot units for the instance fleet, which determines how many Spot instances to provision. For more information, see InstanceFleetConfig in the *Amazon EMR API Reference*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

Amazon EMR Cluster InstanceFleetProvisioningSpecifications

The `InstanceFleetProvisioningSpecifications` property specifies the launch specification for Spot instances in the fleet, which determines the defined duration and provisioning timeout behavior. `InstanceFleetProvisioningSpecifications` is the property type for the `LaunchSpecifications` property of the Amazon EMR Cluster InstanceFleetConfig (p. 1523) property type.

Note
The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SpotSpecification" : SpotProvisioningSpecification (p. 1540)
}
```

YAML

```
SpotSpecification:
  SpotProvisioningSpecification (p. 1540)
```

Properties

`SpotSpecification`

The launch specification for Spot instances in the fleet, which determines the defined duration and provisioning timeout behavior.

Required: Yes

Type: Amazon EMR Cluster SpotProvisioningSpecification (p. 1540)

Update requires: No interruption (p. 120)

Amazon EMR Cluster InstanceGroupConfig

`InstanceGroupConfig` is a property of the `CoreInstanceGroup` and `MasterInstanceGroup` properties of the job flow instances configuration (p. 1529). The `InstanceGroupConfig` property

specifies the settings for instances (nodes) in the core and master instance groups of an Amazon EMR cluster.

Syntax

JSON

```
{
  "AutoScalingPolicy" : AutoScalingPolicy,
  "BidPrice" : String,
  "Configurations" : [ Configuration, ... ],
  "EbsConfiguration" : EBSConfiguration,
  "InstanceCount" : Integer,
  "InstanceType" : String,
  "Market" : String,
  "Name" : String
}
```

YAML

```
AutoScalingPolicy:
  AutoScalingPolicy
BidPrice: String
Configurations:
  - Configuration
EbsConfiguration:
  EBSConfiguration
InstanceCount: Integer
InstanceType: String
Market: String
Name: String
```

Properties

`AutoScalingPolicy`

An automatic scaling policy for a core instance group or task instance group in an Amazon EMR cluster. An automatic scaling policy defines how an instance group dynamically adds and terminates EC2 instances in response to the value of a CloudWatch metric.

Required: No

Update requires: No interruption (p. 120)

Type: Amazon EMR Cluster AutoScalingPolicy (p. 1519)

`BidPrice`

When launching instances as Spot Instances, the bid price in USD for each EC2 instance in the instance group.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Configurations`

A list of configurations to apply to this instance group. For more information see, Configuring Applications in the *Amazon EMR Release Guide*.

Required: No

Type: List of Amazon EMR Cluster Configurations (p. 1522)

Update requires: Replacement (p. 121)

`EbsConfiguration`

Configures Amazon Elastic Block Store (Amazon EBS) storage volumes to attach to your instances.

Required: No

Type: Amazon EMR EbsConfiguration (p. 1559)

Update requires: Replacement (p. 121)

`InstanceCount`

The number of instances to launch in the instance group.

Required: Yes

Type: Integer

`InstanceType`

The EC2 instance type for all instances in the instance group. For more information, see Instance Configurations in the *Amazon EMR Management Guide*.

Required: Yes

Type: String

`Market`

The type of marketplace from which your instances are provisioned into this group, either `ON_DEMAND` or `SPOT`. For more information, see Amazon EC2 Purchasing Options.

Required: No

Type: String

`Name`

A name for the instance group.

Required: No

Type: String

Amazon EMR Cluster InstanceTypeConfig

Use the `InstanceTypeConfig` property to configure an instance types in an instance fleet. This propery determines which EC2 instances that Amazon EMR attempts to provision to fulfill On-Demand and Spot target capacities. You can configure a maximum of five instance types in a fleet. The `InstanceTypeConfigs` property of the Amazon EMR Cluster InstanceFleetConfig (p. 1523) resource contains a list of `InstanceTypeConfig` property types.

> **Note**
> The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "BidPrice" : String,
  "BidPriceAsPercentageOfOnDemandPrice" : Double,
  "Configurations" : [ Configuration (p. 1522), ...],
  "EbsConfiguration" : EbsConfiguration (p. 1559),
  "InstanceType" : String,
  "WeightedCapacity" : Integer
}
```

YAML

```
BidPrice: String
BidPriceAsPercentageOfOnDemandPrice: Double
Configurations:
  - Configuration (p. 1522)
EbsConfiguration:
  EbsConfiguration (p. 1559)
InstanceType: String
WeightedCapacity: Integer
```

Properties

`BidPrice`

The bid price for each EC2 Spot Instance type, as defined by `InstanceType`. `BidPrice` is expressed in USD. For more information, see InstanceTypeConfig in the *Amazon EMR API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`BidPriceAsPercentageOfOnDemandPrice`

The bid price, as a percentage of the On-Demand price, for each EC2 Spot instance as defined by `InstanceType`. `BidPriceAsPercentageOfOnDemandPrice`is expressed as a number. For more information, see InstanceTypeConfig in the *Amazon EMR API Reference*.

Required: No

Type: Double

Update requires: Replacement (p. 121)

`Configurations`

A configuration classification that applies when provisioning cluster instances. This can include configurations for applications and software that run on the cluster. Duplicates are not allowed.

Required: No

Type: List of Amazon EMR Cluster Configurations (p. 1522)

Update requires: Replacement (p. 121)

`EbsConfiguration`

The configuration of Amazon Elastic Block Store (Amazon EBS) that is attached to each instance as defined by `InstanceType`.

Required: No

Type: Amazon EMR EbsConfiguration (p. 1559)

Update requires: Replacement (p. 121)

`InstanceType`

An EC2 instance type, such as `m3.xlarge`. For constraints, see InstanceTypeConfig in the *Amazon EMR API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`WeightedCapacity`

The number of units that a provisioned instance of this type provides toward fulfilling the target capacities defined in `InstanceFleetConfig`. For more information, see InstanceTypeConfig in the *Amazon EMR API Reference*.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

Amazon EMR Cluster JobFlowInstancesConfig

Use the`JobFlowInstancesConfig`, which is a property of the AWS::EMR::Cluster (p. 1501) resource, to configure the EC2 instances (nodes) that will run jobs in an Amazon EMR cluster.

Note
When creating your cluster using `EmrManagedMasterSecurityGroup` and `EmrManagedSlaveSecurityGroup`, to avoid a `delete_failed` exception, use security groups created outside of the AWS CloudFormation stack or retain them on deletion.

Syntax

JSON

```
{
  "AdditionalMasterSecurityGroups" : [ String, ... ],
  "AdditionalSlaveSecurityGroups" : [ String, ... ],
  "CoreInstanceFleet" : InstanceFleetConfig,
  "CoreInstanceGroup" : InstanceGroupConfig,
  "Ec2KeyName" : String,
  "Ec2SubnetId" : String,
  "EmrManagedMasterSecurityGroup" : String,
  "EmrManagedSlaveSecurityGroup" : String,
  "HadoopVersion" : String,
  "MasterInstanceFleet" : InstanceFleetConfig,
  "MasterInstanceGroup" : InstanceGroupConfig,
  "Placement" : Placement,
  "ServiceAccessSecurityGroup" : String,
  "TerminationProtected" : Boolean
}
```

YAML

```
AdditionalMasterSecurityGroups:
  - String
```

```
AdditionalSlaveSecurityGroups:
  - String
CoreInstanceFleet:
  InstanceFleetConfig,
CoreInstanceGroup:
  InstanceGroupConfig
Ec2KeyName: String
Ec2SubnetId: String
EmrManagedMasterSecurityGroup: String
EmrManagedSlaveSecurityGroup: String
HadoopVersion: String
MasterInstanceFleet:
  InstanceFleetConfig
MasterInstanceGroup:
  InstanceGroupConfig
Placement:
  Placement
ServiceAccessSecurityGroup: String
TerminationProtected: Boolean
```

Properties

`AdditionalMasterSecurityGroups`

A list of additional EC2 security group IDs to assign to the master instance (master node) in your Amazon EMR cluster. Use this property to supplement the rules specified by the Amazon EMR managed master security group.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`AdditionalSlaveSecurityGroups`

A list of additional EC2 security group IDs to assign to the slave instances (slave nodes) in your Amazon EMR cluster. Use this property to supplement the rules specified by the Amazon EMR managed slave security group.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`CoreInstanceFleet`

The instance fleet settings for the core instances in your Amazon EMR cluster. Use this property with the `MasterInstanceFleet` property.

> **Note**
> The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Required: No

Type: Amazon EMR Cluster InstanceFleetConfig (p. 1523)

Update requires: Replacement (p. 121)

`CoreInstanceGroup`

The settings for the core instances in your Amazon EMR cluster. Use this property with the `MasterInstanceGroup` property.

Required: No

Type: Amazon EMR Cluster InstanceGroupConfig (p. 1525)

Update requires: Replacement (p. 121)

`Ec2KeyName`

The name of an Amazon Elastic Compute Cloud (Amazon EC2) key pair, which you can use to access the instances in your Amazon EMR cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Ec2SubnetId`

The ID of the subnet where you want to launch your instances.

Required: No

Type: String

Update requires: Replacement (p. 121)

`EmrManagedMasterSecurityGroup`

The ID of an EC2 security group (managed by Amazon EMR) that is assigned to the master instance (master node) in your Amazon EMR cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`EmrManagedSlaveSecurityGroup`

The ID of an EC2 security group (managed by Amazon EMR) that is assigned to the slave instances (slave nodes) in your Amazon EMR cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`HadoopVersion`

The Hadoop version for the job flow. For valid values, see the HadoopVersion parameter in the *Amazon EMR API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`MasterInstanceFleet`

The instance fleet settings for the master instance (master node).

> **Note**
> The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

You must use either `MasterInstanceFleet` or `MasterInstanceGroup` in your configuration. If you use `MasterInstanceFleet`, then you may also specify the `CoreInstanceFleet` property.

Required: No

Type: Amazon EMR Cluster InstanceFleetConfig (p. 1523)

Update requires: Replacement (p. 121)

`MasterInstanceGroup`

The settings for the master instance (master node).

You must use either `MasterInstanceGroup` or `MasterInstanceFleet` in your configuration. If you use `MasterInstanceGroup`, then you may also specify the `CoreInstanceGroup` property.

Required: No

Type: Amazon EMR Cluster InstanceGroupConfig (p. 1525)

Update requires: Replacement (p. 121)

`Placement`

The Availability Zone (AZ) in which the job flow runs.

Required: No

Type: Amazon EMR Cluster PlacementType (p. 1535)

Update requires: Replacement (p. 121)

`ServiceAccessSecurityGroup`

The ID of the EC2 security group (managed by Amazon EMR) that services use to access clusters in private subnets.

Required: No

Type: String

Update requires: Replacement (p. 121)

`TerminationProtected`

Indicates whether to prevent the EC2 instances from being terminated by an API call or user intervention. If you want to delete a stack with protected instances, update this value to `false` before you delete the stack. By default, AWS CloudFormation sets this property to `false`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

Amazon EMR Cluster KerberosAttributes

The `KerberosAttributes` property type specifies attributes for Kerberos configuration when Kerberos authentication is enabled using a security configuration.

`KerberosAttributes` is a property of the AWS::EMR::Cluster (p. 1501) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ADDomainJoinPassword" : String,
  "ADDomainJoinUser" : String,
  "CrossRealmTrustPrincipalPassword" : String,
  "KdcAdminPassword" : String,
  "Realm" : String
}
```

YAML

```
ADDomainJoinPassword: String
ADDomainJoinUser: String
CrossRealmTrustPrincipalPassword: String
KdcAdminPassword: String
Realm: String
```

Properties

`ADDomainJoinPassword`

The Active Directory password for `ADDomainJoinUser`.

Length Constraints: Minimum length of 0. Maximum length of 256.

Pattern: [\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*

Required: No

Type: String

Update requires: No interruption (p. 120)

`ADDomainJoinUser`

Required only when establishing a cross-realm trust with an Active Directory domain. A user with sufficient privileges to join resources to the domain.

Length Constraints: Minimum length of 0. Maximum length of 256.

Pattern: [\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*

Required: No

Type: String

Update requires: No interruption (p. 120)

`CrossRealmTrustPrincipalPassword`

Required only when establishing a cross-realm trust with a KDC in a different realm. The cross-realm principal password, which must be identical across realms.

Length Constraints: Minimum length of 0. Maximum length of 256.

Pattern: [\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*

Required: No

Type: String

Update requires: No interruption (p. 120)

`KdcAdminPassword`

The password used within the cluster for the kadmin service on the cluster-dedicated KDC, which maintains Kerberos principals, password policies, and keytabs for the cluster.

Length Constraints: Minimum length of 0. Maximum length of 256.

Pattern: [\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Realm`

The name of the Kerberos realm to which all nodes in a cluster belong. For example, `EC2.INTERNAL`.

Length Constraints: Minimum length of 0. Maximum length of 256.

Pattern: [\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*

Required: Yes

Type: String

Update requires: No interruption (p. 120)

See Also

- KerberosAttributes in the *Amazon EMR API Reference*
- Use Kerberos Authentication in the *Amazon EMR Management Guide*

Amazon EMR Cluster MetricDimension

The `MetricDimension` property type represents a CloudWatch dimension that you specify using a key–value pair. The `Dimensions` subproperty of the Amazon EMR Cluster CloudWatchAlarmDefinition (p. 1521) property contains a list of one or more `MetricDimension` property types.

Syntax

JSON

```
{
  "Key" : String,
  "Value" : String
}
```

YAML

```
  Key: String
  Value: String
```

Properties

By default, Amazon EMR uses one dimension whose key (known as a `Name` in CloudWatch) is `JobFlowID` and whose value is a variable representing the cluster ID, which is `${emr.clusterId}`. This enables the rule to bootstrap when the cluster ID becomes available.

`Key`

The dimension name.

Required: Yes

Type: String

`Value`

The dimension value.

Required: Yes

Type: String

Amazon EMR Cluster PlacementType

The `PlacementType` property type specifies the Availability Zone (AZ) in which the job flow runs. `PlacementType` is the property type for the `Placement` subproperty of the Amazon EMR Cluster JobFlowInstancesConfig (p. 1529) property type.

Syntax

JSON

```
{
  "AvailabilityZone" : String
}
```

YAML

```
AvailabilityZone: String
```

Properties

`AvailabilityZone`

The Amazon Elastic Compute Cloud (Amazon EC2) AZ for the job flow. For more information, see http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-regions-availability-zones.html in the *Amazon EC2 User Guide for Linux Instances*.

Required: Yes

Type: String

Amazon EMR Cluster ScalingAction

The `ScalingAction` property type specifies the scaling actions for an Auto Scaling group policy. `ScalingAction` is the property type for the `Action` subproperty of the Amazon EMR Cluster ScalingRule (p. 1537) property type.

Syntax

JSON

```
{
  "Market" : String,
  "SimpleScalingPolicyConfiguration" : SimpleScalingPolicyConfiguration
}
```

YAML

```
  Market: String
  SimpleScalingPolicyConfiguration: SimpleScalingPolicyConfiguration
```

Properties

`Market`

Not available for instance groups. Instance groups use the market type specified for the group.

Valid values: `ON_DEMAND` or `SPOT`

Required: No

Type: String

Update requires: No interruption (p. 120)

`SimpleScalingPolicyConfiguration`

The type of adjustment the automatic scaling activity makes when triggered, and the periodicity of the adjustment.

Required: Yes

Type: Amazon EMR Cluster SimpleScalingPolicyConfiguration (p. 1539)

Update requires: No interruption (p. 120)

Amazon EMR Cluster ScalingConstraints

The `ScalingConstraints` property type specifies the upper and lower Amazon EC2 instance limits for an automatic scaling policy. `ScalingConstraints` is the property type for the `Constraints` subproperty of the Amazon EMR Cluster AutoScalingPolicy (p. 1519) property type.

Syntax

JSON

```
{
  "MaxCapacity" : Integer,
  "MinCapacity" : Integer
}
```

YAML

```
MaxCapacity: Integer
MinCapacity: Integer
```

Properties

`MaxCapacity`

The upper boundary of EC2 instances in an instance group beyond which scaling activities are not allowed to grow. Scale-out activities will not add instances beyond this boundary.

Required: Yes

Type: Integer

`MinCapacity`

The lower boundary of EC2 instances in an instance group below which scaling activities are not allowed to shrink. Scale-in activities will not terminate instances below this boundary.

Required: Yes

Type: Integer

Amazon EMR Cluster ScalingRule

The `ScalingRule` property type represents a scale-in or scale-out rule that defines scaling activity, including the CloudWatch metric alarm that triggers activity, how Amazon EC2 instances are added or removed, and the periodicity of adjustments. The `Rules` subproperty of the Amazon EMR Cluster JobFlowInstancesConfig (p. 1529) property contains a list of one or more `ScalingRule` property types.

Syntax

JSON

```
{
  "Action" : ScalingAction,
  "Description" : String,
  "Name" : String,
  "Trigger" : ScalingTrigger
}
```

YAML

```
  Action: ScalingAction
  Description: String
  Name: String
  Trigger: ScalingTrigger
```

Properties

`Action`

The conditions that trigger an automatic scaling activity.

Required: Yes

Type: Amazon EMR Cluster ScalingAction (p. 1535)

`Description`

A friendly, more verbose description of the automatic scaling rule.

Required: No

Type: String

`Name`

The name used to identify an automatic scaling rule. Rule names must be unique within a scaling policy.

Required: Yes

Type: String

`Trigger`

The CloudWatch alarm definition that determines when automatic scaling activity is triggered.

Required: Yes

Type: Amazon EMR Cluster ScalingTrigger (p. 1538)

Amazon EMR Cluster ScalingTrigger

The `ScalingTrigger` property type specifies the conditions that trigger an automatic scaling activity. `ScalingTrigger` is the property type for the `Trigger` subproperty of the Amazon EMR Cluster ScalingRule (p. 1537) property type.

Syntax

JSON

```
{
  "CloudWatchAlarmDefinition" : CloudWatchAlarmDefinition
}
```

YAML

```
  CloudWatchAlarmDefinition: CloudWatchAlarmDefinition
```

Properties

`CloudWatchAlarmDefinition`

The definition of a CloudWatch metric alarm. When the defined alarm conditions are met along with other trigger parameters, scaling activity begins.

Required: Yes

Type: Amazon EMR Cluster CloudWatchAlarmDefinition (p. 1521)

Update requires: No interruption (p. 120)

Amazon EMR Cluster ScriptBootstrapActionConfig

`ScriptBootstrapActionConfig` is a property of the Amazon EMR Cluster BootstrapActionConfig (p. 1520) property that specifies the arguments and location of the bootstrap script that Amazon EMR (Amazon EMR) runs before it installs applications on the cluster nodes.

Syntax

JSON

```
{
  "Args" : [ String, ... ],
  "Path" : String
}
```

YAML

```
Args:
  - String
Path: String
```

Properties

`Args`

A list of command line arguments to pass to the bootstrap action script.

Required: No

Type: List of String values

`Path`

The location of the script that Amazon EMR runs during a bootstrap action. Specify a location in an S3 bucket or your local file system.

Required: Yes

Type: String

Amazon EMR Cluster SimpleScalingPolicyConfiguration

`SimpleScalingPolicyConfiguration` is a subproperty of the Amazon EMR Cluster ScalingAction (p. 1535) property. It specifies an automatic scaling configuration that describes how the policy adds or removes instances, the cooldown period, and the number of Amazon EC2 instances that will be added each time the CloudWatch metric alarm condition is satisfied.

Syntax

JSON

```
{
   "AdjustmentType" : String,
   "CoolDown" : Integer,
   "ScalingAdjustment" : String
 }
```

YAML

```
   AdjustmentType: String
   CoolDown: Integer
   ScalingAdjustment: String
```

Properties

Note
For more information about the constraints and valid values of each property, see the SimpleScalingPolicyConfiguration data type in the *Amazon EMR API Reference*.

`AdjustmentType`

The way in which Amazon EC2 instances are added (if `ScalingAdjustment` is a positive number) or terminated (if `ScalingAdjustment` is a negative number) each time the scaling activity is triggered. `CHANGE_IN_CAPACITY` is the default.

Required: No

Type: String

`CoolDown`

The amount of time, in seconds, after a scaling activity completes before any further trigger-related scaling activities can start. The default value is 0.

Required: No

Type: Integer

`ScalingAdjustment`

The amount by which to scale in or scale out, based on the specified `AdjustmentType`. A positive value adds to the instance group's Amazon EC2 instance count while a negative number removes instances. If `AdjustmentType` is set to `EXACT_CAPACITY`, the number should only be a positive integer. If `AdjustmentType` is set to `PERCENT_CHANGE_IN_CAPACITY`, the value should express the percentage as a decimal.

Required: Yes

Type: Integer

Amazon EMR Cluster SpotProvisioningSpecification

The `SpotProvisioningSpecification` property specifies the duration and timeout behavior for Spot instances in the instance fleet for Amazon EMR. `SpotProvisioningSpecification` is the property type for the `SpotSpecification` subproperty of the Amazon EMR Cluster InstanceFleetProvisioningSpecifications (p. 1525) property type.

Note
The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "BlockDurationMinutes" : Integer,
  "TimeoutAction" : String,
  "TimeoutDurationMinutes" : Integer
}
```

YAML

```
BlockDurationMinutes: Integer
TimeoutAction: String
TimeoutDurationMinutes: Integer
```

Properties

`BlockDurationMinutes`

The defined duration for Spot instances (also known as Spot blocks) in minutes. For more information, see SpotProvisioningSpecification in the *Amazon EMR API Reference*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`TimeoutAction`

The action to take when TargetSpotCapacity has not been fulfilled when the TimeoutDurationMinutes has expired. For more information, see SpotProvisioningSpecification in the *Amazon EMR API Reference*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`TimeoutDurationMinutes`

The spot provisioning timeout period in minutes. For more information, see SpotProvisioningSpecification in the *Amazon EMR API Reference*.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

AWS::EMR::InstanceFleetConfig

Use the `AWS::EMR::InstanceFleetConfig` resource to configure a Spot Instance fleet for an Amazon EMR cluster. For more information, see Configure Instance Fleets in the *Amazon EMR Management Guide*.

> **Note**
> The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EMR::InstanceFleetConfig",
  "Properties" : {
    "ClusterId" : String,
```

```
    "InstanceFleetType" : String,
    "InstanceTypeConfigs" : [ InstanceTypeConfig (p. 1546), ... ],
    "LaunchSpecifications" : InstanceFleetProvisioningSpecifications (p. 1546),
    "Name" : String,
    "TargetOnDemandCapacity" : Integer,
    "TargetSpotCapacity" : Integer
  }
}
```

YAML

```
Type: AWS::EMR::InstanceFleetConfig
Properties:
  ClusterId: String
  InstanceFleetType: String
  InstanceTypeConfigs:
    - InstanceTypeConfig (p. 1546)
  LaunchSpecifications:
    InstanceFleetProvisioningSpecifications (p. 1546)
  Name: String
  TargetOnDemandCapacity: Integer
  TargetSpotCapacity: Integer
```

Properties

For more information about each property, including constraints and valid values, see InstanceFleetConfig in the *Amazon EMR API Reference*.

`ClusterId`

The ID of the target cluster.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`InstanceFleetType`

The node type that the instance fleet hosts. Valid values are `MASTER`, `CORE`, and `TASK`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`InstanceTypeConfigs`

The instance type configurations that define the EC2 instances in the instance fleet. Duplicates not allowed.

Required: No

Type: List of Amazon EMR InstanceFleetConfig InstanceTypeConfig (p. 1546)

Update requires: Replacement (p. 121)

`LaunchSpecifications`

The launch specification for the instance fleet.

Required: No

Type: Amazon EMR InstanceFleetConfig InstanceFleetProvisioningSpecifications (p. 1546)

Update requires: Replacement (p. 121)

`Name`

The friendly name of the instance fleet. For constraints, see InstanceFleetConfig in the *Amazon EMR API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`TargetOnDemandCapacity`

The target capacity of On-Demand units for the instance fleet. This determines how many On-Demand Instances to provision. For more information, see InstanceFleetConfig in the *Amazon EMR API Reference*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`TargetSpotCapacity`

The target capacity of Spot units for the instance fleet. This determines how many Spot Instances to provision. For more information, see InstanceFleetConfig in the *Amazon EMR API Reference*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

Amazon EMR InstanceFleetConfig Configuration

Use the `Configuration` property to configure fleet instances for Amazon EMR and applications and software bundled with Amazon EMR. For more information, see Configuring Applications in the *Amazon EMR Release Guide*. `Configuration` is a subproperty of the Amazon EMR InstanceFleetConfig InstanceTypeConfig (p. 1546) property.

Note
The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
"Classification" : String,
"ConfigurationProperties" : { String:String, ... },
"Configurations" : [ Configuration (p. 1543), ... ]
```

YAML

```
Classification: String
ConfigurationProperties:
```

```
  String: String
Configurations:
  - Configuration (p. 1543)
```

Properties

`Classification`

The application-specific configuration file.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ConfigurationProperties`

Within a configuration classification, a set of properties that represent the settings that you want to change in the configuration file. Duplicates not allowed.

Required: No

Type: String to String map

Update requires: Replacement (p. 121)

`Configurations`

The list of additional configurations to apply within a configuration object. Duplicates not allowed.

Required: No

Type: List of Amazon EMR InstanceFleetConfig Configuration (p. 1543)

Update requires: Replacement (p. 121)

Amazon EMR InstanceFleetConfig EbsBlockDeviceConfig

Use the `EbsBlockDeviceConfig` property to specify the settings for the Amazon EBS volumes that Amazon EMR associates with your instances. The `EbsBlockDeviceConfigs` subproperty of the Amazon EMR InstanceFleetConfig EbsConfiguration (p. 1545) property contains a list of `EbsBlockDeviceConfig` property types.

> **Note**
> The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "VolumeSpecification" : VolumeSpecification (p. 1549),
  "VolumesPerInstance" : Integer
}
```

YAML

```
VolumeSpecification:
```

```
  VolumeSpecification (p. 1549)
VolumesPerInstance: Integer
```

Properties

`VolumeSpecification`

Amazon EBS volume specifications, such as volume type, IOPS, and size (GiB), for the EBS volume attached to an EC2 instance in the fleet.

Required: Yes

Type: Amazon EMR InstanceFleetConfig VolumeSpecification (p. 1549)

Update requires: Replacement (p. 121)

`VolumesPerInstance`

The number of Amazon EBS volumes with a specific volume configuration that are associated with every instance in the fleet.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

Amazon EMR InstanceFleetConfig EbsConfiguration

Use the `EbsConfiguration` property to specify the Amazon EBS configuration of an Amazon EMR fleet instance. `EbsConfiguration` is a subproperty of the Amazon EMR InstanceFleetConfig InstanceTypeConfig (p. 1546) property.

Note
The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "EbsBlockDeviceConfigs" : [ EbsBlockDeviceConfig (p. 1544), ...],
  "EbsOptimized" : Boolean
}
```

YAML

```
EbsBlockDeviceConfigs:
  - EbsBlockDeviceConfig (p. 1544)
EbsOptimized: Boolean
```

Properties

`EbsBlockDeviceConfigs`

A list of Amazon EBS volume specifications that are attached to an instance. Duplicates not allowed.

Required: No

Type: List of Amazon EMR InstanceFleetConfig EbsBlockDeviceConfig (p. 1544)

Update requires: Replacement (p. 121)

`EbsOptimized`

Indicates whether an Amazon EBS volume is EBS-optimized.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

Amazon EMR InstanceFleetConfig InstanceFleetProvisioningSpecifications

Use the `InstanceFleetProvisioningSpecifications` property type to create or modify the launch specification for Spot Instances in the fleet. This determines the defined duration and provisioning timeout behavior. `InstanceFleetProvisioningSpecifications` is the property type for the `LaunchSpecifications` property of the AWS::EMR::InstanceFleetConfig (p. 1541) resource.

> **Note**
> The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SpotSpecification" : SpotProvisioningSpecification (p. 1548)
}
```

YAML

```
SpotSpecification:
  SpotProvisioningSpecification (p. 1548)
```

Properties

`SpotSpecification`

The launch specification for Spot Instances in the fleet. This determines the defined duration and provisioning timeout behavior.

Required: Yes

Type: Amazon EMR InstanceFleetConfig SpotProvisioningSpecification (p. 1548)

Update requires: No interruption (p. 120)

Amazon EMR InstanceFleetConfig InstanceTypeConfig

Use the `InstanceTypeConfig` property to configure each instance type in an instance fleet. This configuration determines which EC2 instances that Amazon EMR attempts to provision to fulfill On-

Demand and Spot target capacities. You can configure a maximum of five instance types in a fleet. For a list of `InstanceTypeConfig` property types, see the `InstanceTypeConfigs` property of the AWS::EMR::InstanceFleetConfig (p. 1541) resource.

> **Note**
> The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "BidPrice" : String,
  "BidPriceAsPercentageOfOnDemandPrice" : Double,
  "Configurations" : [ Configuration (p. 1543), ... ],
  "EbsConfiguration" : EbsConfiguration (p. 1545),
  "InstanceType" : String,
  "WeightedCapacity" : Integer
}
```

YAML

```
BidPrice: String
BidPriceAsPercentageOfOnDemandPrice: Double
Configurations:
  - Configuration (p. 1543)
EbsConfiguration:
  EbsConfiguration (p. 1545)
InstanceType: String
WeightedCapacity: Integer
```

Properties

For more information about each property, including constraints and valid values, see see InstanceTypeConfig in the *Amazon EMR API Reference*.

`BidPrice`

The bid price for each EC2 Spot Instance type as defined by `InstanceType`. `BidPrice` is expressed in USD. For more information, see InstanceTypeConfig in the *Amazon EMR API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`BidPriceAsPercentageOfOnDemandPrice`

The bid price, as a percentage of the On-Demand price, for each EC2 Spot Instance as defined by `InstanceType`. `BidPriceAsPercentageOfOnDemandPrice` is expressed as a number. For more information, see InstanceTypeConfig in the *Amazon EMR API Reference*.

Required: No

Type: Double

Update requires: Replacement (p. 121)

`Configurations`

A configuration classification that applies when provisioning cluster instances. You can use this property to configure applications and software that run on the cluster. Duplicates are not allowed.

Required: No

Type: List of Amazon EMR InstanceFleetConfig Configuration (p. 1543)

Update requires: Replacement (p. 121)

`EbsConfiguration`

The configuration of Amazon Elastic Block Store (Amazon EBS) that is attached to each instance as defined by `InstanceType`.

Required: No

Type: Amazon EMR InstanceFleetConfig EbsConfiguration (p. 1545)

Update requires: Replacement (p. 121)

`InstanceType`

An EC2 instance type, such as `m3.xlarge`. For constraints, see InstanceTypeConfig in the *Amazon EMR API Reference.*

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`WeightedCapacity`

The number of units that a provisioned instance of this type provides toward fulfilling the target capacities defined in `InstanceFleetConfig`. For more information, see InstanceTypeConfig in the *Amazon EMR API Reference*.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

Amazon EMR InstanceFleetConfig SpotProvisioningSpecification

Use the `SpotProvisioningSpecification` property to specify the duration and timeout behavior for Spot Instances in the instance fleet for Amazon EMR. `SpotProvisioningSpecification` is the property type for the `SpotSpecification` subproperty of the Amazon EMR InstanceFleetConfig InstanceFleetProvisioningSpecifications (p. 1546) property type.

Note
The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "BlockDurationMinutes" : Integer,
  "TimeoutAction" : String,
  "TimeoutDurationMinutes" : Integer
}
```

YAML

```
BlockDurationMinutes: Integer
TimeoutAction: String
TimeoutDurationMinutes: Integer
```

Properties

`BlockDurationMinutes`

The defined duration for Spot Instances (also known as Spot blocks) in minutes. For more information, see SpotProvisioningSpecification in the *Amazon EMR API Reference*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`TimeoutAction`

The action to take when the capacity for the target Spot Instance, as specified in `TargetSpotCapacity`, has not been fulfilled before the time specified in `TimeoutDurationMinutes` has expired. For more information, see SpotProvisioningSpecification in the *Amazon EMR API Reference*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`TimeoutDurationMinutes`

The timeout period for spot provisioning, in minutes. For more information, see SpotProvisioningSpecification in the *Amazon EMR API Reference*.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

Amazon EMR InstanceFleetConfig VolumeSpecification

Use the `VolumeSpecification` property to specify settings—such as volume type, IOPS, and size (GiB)—for the Amazon EBS volume attached to an EC2 instance in the fleet. `VolumeSpecification` is a subproperty of the Amazon EMR InstanceFleetConfig EbsBlockDeviceConfig (p. 1544) property.

> **Note**
> The instance fleet configuration is available only in Amazon EMR versions 4.8.0 and later, excluding 5.0.x versions.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Iops" : Integer,
  "SizeInGB" : Integer,
  "VolumeType" : String
}
```

YAML

```
Iops: Integer
SizeInGB: Integer
VolumeType: String
```

Properties

`Iops`

The number of I/O operations per second (IOPS) that the volume supports.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`SizeInGB`

The volume size, in gibibytes (GiB). For valid values, see VolumeSpecification in the *Amazon EMR API Reference*.

Required: Yes

Type: Integer

Update requires: Replacement (p. 121)

`VolumeType`

The volume type. For valid values, see VolumeSpecification in the *Amazon EMR API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

AWS::EMR::InstanceGroupConfig

The `AWS::EMR::InstanceGroupConfig` resource configures a task instance group for an Amazon EMR cluster.

> **Note**
> You can't delete an instance group. If you remove an instance group, AWS CloudFormation sets the instance count to zero (`0`).

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EMR::InstanceGroupConfig",
  "Properties" : {
    "AutoScalingPolicy" : AutoScalingPolicy,
    "BidPrice" : String,
    "Configurations" : [ Configuration, ... ],
    "EbsConfiguration" : EBSConfiguration,
    "InstanceCount" : Integer,
    "InstanceRole" : String,
    "InstanceType" : String,
    "JobFlowId": String,
    "Market" : String,
    "Name" : String
  }
}
```

YAML

```
Type: AWS::EMR::InstanceGroupConfig
Properties:
  AutoScalingPolicy:
    AutoScalingPolicy
  BidPrice: String
  Configurations:
    - Configuration
  EbsConfiguration" :
    EBSConfiguration
  InstanceCount" : Integer
  InstanceRole" : String
  InstanceType" : String
  JobFlowId": String
  Market" : String
  Name" : String
```

Properties

Note
For more information about the constraints and valid values of each property, see the InstanceGroupConfig in the Amazon EMR API Reference.

`AutoScalingPolicy`

An automatic scaling policy for a core instance group or task instance group in an Amazon EMR cluster. An automatic scaling policy defines how an instance group dynamically adds and terminates EC2 instances in response to the value of a CloudWatch metric. For more information, see PutAutoScalingPolicy in the Amazon EMR API Reference.

Required: No

Type: Amazon EMR InstanceGroupConfig AutoScalingPolicy (p. 1554)

Update requires: No interruption (p. 120)

`BidPrice`

The bid price in USD for each Amazon EC2 instance in the instance group when launching instances (nodes) as Spot Instances.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Configurations`

A list of configurations to apply to this instance group. For more information see, Configuring Applications in the *Amazon EMR Release Guide*.

Required: No

Type: List of Amazon EMR Cluster Configurations (p. 1522)

Update requires: Replacement (p. 121)

`EbsConfiguration`

Configures Amazon Elastic Block Store (Amazon EBS) storage volumes to attach to your instances.

Required: No

Type: Amazon EMR EbsConfiguration (p. 1559)

Update requires: Replacement (p. 121)

`InstanceCount`

The number of instances to launch in the instance group.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

`InstanceRole`

The role of the servers in the Amazon EMR cluster, such as `TASK`. For more information, see Instance Groups in the *Amazon EMR Management Guide*.

> **Note**
> Currently, the only valid value is `TASK`. You configure the master and core instance groups as part of the AWS::EMR::Cluster (p. 1501) resource.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`InstanceType`

The EC2 instance type for all instances in the instance group. For more information, see Instance Configurations in the *Amazon EMR Management Guide*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`JobFlowId`

The ID of an Amazon EMR cluster that you want to associate this instance group with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Market`

The type of marketplace from which your instances are provisioned into this group, either `ON_DEMAND` or `SPOT`. For more information, see Amazon EC2 Purchasing Options.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Name`

A name for the instance group.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the instance group ID, such as `ig-ABC12DEF3456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example adds a task instance group to the `TestCluster` cluster. The instance group contains two m3.xlarge instances.

JSON

```
"TestInstanceGroupConfig": {
  "Type": "AWS::EMR::InstanceGroupConfig",
  "Properties": {
    "InstanceCount": 2,
    "InstanceType": "m3.xlarge",
    "InstanceRole": "TASK",
    "Market": "ON_DEMAND",
    "Name": "cfnTask2",
    "JobFlowId": {
      "Ref": "cluster"
    }
  }
}
```

YAML

```
TestInstanceGroupConfig:
  Type: AWS::EMR::InstanceGroupConfig
  Properties:
    InstanceCount: 2
```

```
    InstanceType: "m3.xlarge"
    InstanceRole: "TASK"
    Market: "ON_DEMAND"
    Name: "cfnTask2"
    JobFlowId:
      Ref: "cluster"
```

Amazon EMR InstanceGroupConfig AutoScalingPolicy

`AutoScalingPolicy` is a property of the AWS::EMR::InstanceGroupConfig (p. 1550) resource that specifies the constraints and rules for an Auto Scaling group policy. For more information, see PutAutoScalingPolicy in the Amazon EMR API Reference.

Syntax

JSON

```
{
  "Constraints" : ScalingConstraints,
  "Rules" : [ ScalingRule ]
}
```

YAML

```
Constraints:
  ScalingConstraints
Rules:
  - ScalingRule
```

Properties

`Constraints`

The upper and lower Amazon EC2 instance limits for an automatic scaling policy. Automatic scaling activity doesn't cause an instance group to grow above or below these limits.

Required: Yes

Type: Amazon EMR InstanceGroupConfig ScalingConstraints (p. 1561)

Update requires: No interruption (p. 120)

`Rules`

The scale-in and scale-out rules that compose the automatic scaling policy.

Required: Yes

Type: List of Amazon EMR InstanceGroupConfig ScalingRule (p. 1562)

Update requires: No interruption (p. 120)

Example

The following example defines an `AutoScalingPolicy` for an `InstanceGroupConfig` resource.

JSON

```
"MyInstanceGroupConfig": {
```

```
"Type": "AWS::EMR::InstanceGroupConfig",
"Properties": {
  "InstanceCount": 1,
  "InstanceType": {
    "Ref": "InstanceType"
  },
  "InstanceRole": "TASK",
  "Market": "ON_DEMAND",
  "Name": "cfnTask",
  "JobFlowId": {
    "Ref": "MyCluster"
  },
  "AutoScalingPolicy": {
    "Constraints": {
      "MinCapacity": {
        "Ref": "MinCapacity"
      },
      "MaxCapacity": {
        "Ref": "MaxCapacity"
      }
    },
    "Rules": [
      {
        "Name": "Scale-out",
        "Description": "Scale-out policy",
        "Action": {
          "SimpleScalingPolicyConfiguration": {
            "AdjustmentType": "CHANGE_IN_CAPACITY",
            "ScalingAdjustment": 1,
            "CoolDown": 300
          }
        },
        "Trigger": {
          "CloudWatchAlarmDefinition": {
            "Dimensions": [
              {
                "Key": "JobFlowId",
                "Value": "${emr.clusterId}"
              }
            ],
            "EvaluationPeriods": 1,
            "Namespace": "AWS/ElasticMapReduce",
            "Period": 300,
            "ComparisonOperator": "LESS_THAN",
            "Statistic": "AVERAGE",
            "Threshold": 15,
            "Unit": "PERCENT",
            "MetricName": "YARNMemoryAvailablePercentage"
          }
        }
      },
      {
        "Name": "Scale-in",
        "Description": "Scale-in policy",
        "Action": {
          "SimpleScalingPolicyConfiguration": {
            "AdjustmentType": "CHANGE_IN_CAPACITY",
            "ScalingAdjustment": -1,
            "CoolDown": 300
          }
        },
        "Trigger": {
          "CloudWatchAlarmDefinition": {
            "Dimensions": [
              {
                "Key": "JobFlowId",
```

```
                "Value": "${emr.clusterId}"
              }
            ],
            "EvaluationPeriods": 1,
            "Namespace": "AWS/ElasticMapReduce",
            "Period": 300,
            "ComparisonOperator": "GREATER_THAN",
            "Statistic": "AVERAGE",
            "Threshold": 75,
            "Unit": "PERCENT",
            "MetricName": "YARNMemoryAvailablePercentage"
          }
        }
      }
    ]
  }
 }
}
```

YAML

```
MyInstanceGroupConfig:

            Unit: PERCENT
            MetricName: YARNMemoryAvailablePercentage
```

Amazon EMR InstanceGroupConfig CloudWatchAlarmDefinition

The `CloudWatchAlarmDefinition` property specifies the conditions that trigger an automatic scaling activity. `CloudWatchAlarmDefinition` is a subproperty of the Amazon EMR InstanceGroupConfig ScalingTrigger (p. 1563) property type.

Syntax

JSON

```
{
  "ComparisonOperator" : String,
  "Dimensions" : [ MetricDimension, ... ],
  "EvaluationPeriods" : Integer,
  "MetricName" : String,
  "Namespace" : String,
  "Period" : Integer,
  "Statistic" : String,
  "Threshold" : Double,
  "Unit" : String
}
```

YAML

```
  ComparisonOperator: String
  Dimensions:
    - MetricDimension
  EvaluationPeriods: Integer
  MetricName: String
  Namespace: String
  Period: Integer
  Statistic: String
  Threshold: Double
  Unit: String
```

Properties

`ComparisonOperator`

Determines how the metric specified by `MetricName` is compared to the value specified by `Threshold`.

Valid values: `GREATER_THAN_OR_EQUAL`, `GREATER_THAN`, `LESS_THAN`, or `LESS_THAN_OR_EQUAL`.

Required: Yes

Type: String

`Dimensions`

A list of CloudWatch metric dimensions.

Required: No

Type: List of Amazon EMR InstanceGroupConfig MetricDimension (p. 1560)

`EvaluationPeriods`

The number of periods, expressed in seconds using the `Period` property, during which the alarm condition must exist before the alarm triggers automatic scaling activity. The default value is 1.

Required: No

Type: Integer

`MetricName`

The name of the CloudWatch metric that is watched to determine an alarm condition.

Required: Yes

Type: String

`Namespace`

The namespace for the CloudWatch metric. The default is `AWS/ElasticMapReduce`.

Required: No

Type: String

`Period`

The period, in seconds, over which the statistic for applying the metric associated with the alarm is applied. You specify the statistic in the `Statistic` property. CloudWatch metrics for Amazon EMR are emitted every five minutes (300 seconds). If you specify a CloudWatch metric for Amazon EMR, specify 300.

Required: Yes

Type: Integer

`Statistic`

The statistic to apply to the metric associated with the alarm. The default is `AVERAGE`.

Valid values: `SAMPLE_COUNT`, `AVERAGE`, `SUM`, `MINIMUM`, and `MAXIMUM`.

Required: No

Type: String

`Threshold`

The value against which the specified statistic is compared.

Required: Yes

Type: Double

`Unit`

The unit of measure associated with the CloudWatch metric being watched. Specify the unit specified in the CloudWatch metric.

For more information, see CloudWatchAlarmDefinition in the *Amazon EMR API Reference*.

Required: No

Type: String

Amazon EMR EbsConfiguration

`EbsConfiguration` is a property of the Amazon EMR Cluster InstanceGroupConfig (p. 1525) property and the AWS::EMR::InstanceGroupConfig (p. 1550) resource that defines Amazon Elastic Block Store (Amazon EBS) storage volumes to attach to your Amazon EMR (Amazon EMR) instances.

Syntax

JSON

```
{
  "EbsBlockDeviceConfigs" : [ EbsBlockDeviceConfig, ... ],
  "EbsOptimized" : Boolean
}
```

YAML

```
EbsBlockDeviceConfigs:
  - EbsBlockDeviceConfig
EbsOptimized: Boolean
```

Properties

`EbsBlockDeviceConfigs`

Configures the block storage devices that are associated with your EMR instances.

Required: No

Type: List of Amazon EMR EbsConfiguration EbsBlockDeviceConfigs (p. 1559)

`EbsOptimized`

Indicates whether the instances are optimized for Amazon EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal EBS I/O performance. For more information about fees and supported instance types, see EBS-Optimized Instances in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: Boolean

Default value: `false`

Amazon EMR EbsConfiguration EbsBlockDeviceConfigs

`EbsBlockDeviceConfigs` is a property of the Amazon EMR EbsConfiguration (p. 1559) property that defines the settings for the Amazon Elastic Block Store (Amazon EBS) volumes that Amazon EMR (Amazon EMR) associates with your instances.

Syntax

JSON

```
{
```

```
  "VolumeSpecification" : VolumeSpecification,
  "VolumesPerInstance" : Integer
}
```

YAML

```
VolumeSpecification:
  VolumeSpecification
VolumesPerInstance: Integer
```

Properties

`VolumeSpecification`

The settings for the Amazon EBS volumes.

Required: Yes

Type: Amazon EMR EbsConfiguration EbsBlockDeviceConfig VolumeSpecification (p. 1565)

`VolumesPerInstance`

The number of Amazon EBS volumes that you want to create for each instance in the EMR cluster or instance group. The number cannot be 0.

Required: No

Type: Integer

Amazon EMR InstanceGroupConfig MetricDimension

The `MetricDimension` property type represents a CloudWatch dimension that you specify using a key–value pair. The `Dimensions` subproperty of the Amazon EMR InstanceGroupConfig CloudWatchAlarmDefinition (p. 1557) property contains a list of one or more `MetricDimension` property types.

Syntax

JSON

```
{
  "Key" : String,
  "Value" : String
}
```

YAML

```

  Key: String
  Value: String
```

Properties

By default, Amazon EMR uses one dimension whose key (known as a `Name` in CloudWatch) is `JobFlowID` and whose value is a variable representing the cluster ID, which is `${emr.clusterId}`. This enables the rule to bootstrap when the cluster ID becomes available.

`Key`

The dimension name.

Required: Yes

Type: String

`Value`

The dimension value.

Required: Yes

Type: String

Amazon EMR InstanceGroupConfig ScalingAction

The `ScalingAction` property type specifies the scaling actions for an Auto Scaling group policy. `ScalingAction` is the property type for the `Action` subproperty of the Amazon EMR InstanceGroupConfig ScalingRule (p. 1562) property type.

Syntax

JSON

```
{
  "Market" : String,
  "SimpleScalingPolicyConfiguration" : SimpleScalingPolicyConfiguration
}
```

YAML

```
  Market: String
  SimpleScalingPolicyConfiguration: SimpleScalingPolicyConfiguration
```

Properties

`Market`

Not available for instance groups. Instance groups use the market type specified for the group.

Valid values: `ON_DEMAND` or `SPOT`.

Required: No

Type: String

`SimpleScalingPolicyConfiguration`

The type of adjustment that the automatic scaling activity makes when triggered, and the periodicity of the adjustment.

Required: Yes

Type: Amazon EMR InstanceGroupConfig SimpleScalingPolicyConfiguration (p. 1564)

Amazon EMR InstanceGroupConfig ScalingConstraints

The `ScalingConstraints` property type specifies the upper and lower EC2 instance limits for an automatic scaling policy. `ScalingConstraints` is the property type for the `Constraints` subproperty of the Amazon EMR InstanceGroupConfig AutoScalingPolicy (p. 1554) property type.

Syntax

JSON

```
{
  "MaxCapacity" : Integer,
  "MinCapacity" : Integer
}
```

YAML

```
MaxCapacity: Integer
MinCapacity: Integer
```

Properties

`MaxCapacity`

For autoscaling, the maximum number of EC2 instances in an instance group. Scale-out activities add instances only up to this boundary.

Required: Yes

Type: Integer

`MinCapacity`

For autoscaling, the minimum number of EC2 instances in an instance group. Scale-in activities do not terminate instances below this boundary.

Required: Yes

Type: Integer

Amazon EMR InstanceGroupConfig ScalingRule

The `ScalingRule` property type represents a scale-in or scale-out rule that defines scaling activity, including the CloudWatch metric alarm that triggers activity, how EC2 instances are added or removed, and the periodicity of adjustments. The `Rules` subproperty of the Amazon EMR InstanceGroupConfig AutoScalingPolicy (p. 1554) property contains a list of one or more `ScalingRule` property types.

Syntax

JSON

```
{
  "Action" : ScalingAction,
  "Description" : String,
  "Name" : String,
  "Trigger" : ScalingTrigger
}
```

YAML

```

  Action: ScalingAction
  Description: String
  Name: String
  Trigger: ScalingTrigger
```

Properties

`Action`

The conditions that trigger an automatic scaling activity.

Required: Yes

Type: Amazon EMR InstanceGroupConfig ScalingAction (p. 1561)

`Description`

A friendly, more verbose description of the automatic scaling rule.

Required: No

Type: String

`Name`

The identifier of the automatic scaling rule. Rule names must be unique within a scaling policy.

Required: Yes

Type: String

`Trigger`

The CloudWatch alarm definition that determines when automatic scaling activity is triggered.

Required: Yes

Type: Amazon EMR InstanceGroupConfig ScalingTrigger (p. 1563)

Amazon EMR InstanceGroupConfig ScalingTrigger

The `ScalingTrigger` property type specifies the conditions that trigger an automatic scaling activity. `ScalingTrigger` is the property type for the `Trigger` subproperty of the Amazon EMR InstanceGroupConfig ScalingRule (p. 1562) property type.

Syntax

JSON

```
{
  "CloudWatchAlarmDefinition" : CloudWatchAlarmDefinition
}
```

YAML

```
  CloudWatchAlarmDefinition: CloudWatchAlarmDefinition
```

Properties

`CloudWatchAlarmDefinition`

The definition of a CloudWatch metric alarm. When the defined alarm conditions are met along with other trigger parameters, scaling activity begins.

Required: Yes

Type: Amazon EMR InstanceGroupConfig CloudWatchAlarmDefinition (p. 1557)

Amazon EMR InstanceGroupConfig SimpleScalingPolicyConfiguration

`SimpleScalingPolicyConfiguration` specifies an automatic scaling configuration that describes how the policy adds or removes instances, the cooldown period, and the number of EC2 instances that are added when the CloudWatch metric alarm condition is met. `SimpleScalingPolicyConfiguration` is a subproperty of the Amazon EMR InstanceGroupConfig ScalingAction (p. 1561) property type.

Syntax

JSON

```
{
  "AdjustmentType" : String,
  "CoolDown" : Integer,
  "ScalingAdjustment" : String
}
```

YAML

```
  AdjustmentType: String
  CoolDown: Integer
  ScalingAdjustment: String
```

Properties

Note
For more information about each property, including constraints and valid values, see SimpleScalingPolicyConfiguration in the *Amazon EMR API Reference*.

`AdjustmentType`

The way in which EC2 instances are added (if `ScalingAdjustment` is a positive number) or terminated (if `ScalingAdjustment` is a negative number) when the scaling activity is triggered. `CHANGE_IN_CAPACITY` is the default value.

Required: No

Type: String

`CoolDown`

The amount of time, in seconds, after a scaling activity completes before any further trigger-related scaling activities can start. The default value is 0.

Required: No

Type: Integer

`ScalingAdjustment`

The amount by which to scale the instance group, based on the specified `AdjustmentType`. A positive value adds to the instance group's EC2 instance count. A negative number removes instances. If `AdjustmentType` is set to `EXACT_CAPACITY`, specify only a positive integer. If `AdjustmentType` is set to `PERCENT_CHANGE_IN_CAPACITY`, express the value of the percentage as a decimal. For example, `-0.20` indicates a decrease in 20% increments of cluster capacity.

Required: Yes

Type: Integer

Amazon EMR EbsConfiguration EbsBlockDeviceConfig VolumeSpecification

`VolumeSpecification` is a property of the Amazon EMR EbsConfiguration (p. 1559) property that configures the Amazon Elastic Block Store (Amazon EBS) volumes that Amazon EMR (Amazon EMR) associates with your instances.

Syntax

JSON

```
{
  "Iops" : Integer,
  "SizeInGB" : Integer,
  "VolumeType" : String
}
```

YAML

```
Iops: Integer
SizeInGB: Integer
VolumeType: String
```

Properties

`Iops`

The number of I/O operations per second (IOPS) that the volume supports. For more information, see Iops for the `EbsBlockDevice` action in the *Amazon EC2 API Reference*.

Required: No

Type: Integer

`SizeInGB`

The volume size, in Gibibytes (GiB). For more information about specifying the volume size, see VolumeSize for the `EbsBlockDevice` action in the *Amazon EC2 API Reference*.

Required: Yes

Type: Integer

`VolumeType`

The volume type, such as `standard` or `io1`. For more information about specifying the volume type, see VolumeType for the `EbsBlockDevice` action in the *Amazon EC2 API Reference*.

Required: Yes

Type: String

AWS::EMR::SecurityConfiguration

The `AWS::EMR::SecurityConfiguration` resource creates a security configuration that is stored in the Amazon EMR web service. You can specify the security configuration when creating a cluster. For more information, see Specifying Amazon EMR Encryption Options Using a Security Configuration in the *Amazon EMR Release Guide*.

Topics

- Syntax (p. 1566)

- Properties (p. 1566)
- Return Values (p. 1566)
- Example (p. 1567)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EMR::SecurityConfiguration",
  "Properties" : {
    "Name" : String,
    "SecurityConfiguration" : String
  }
}
```

YAML

```
Type: AWS::EMR::SecurityConfiguration
Properties:
  Name: String
  SecurityConfiguration: String
```

Properties

For more information about each property, including constraints and valid values, see CreateSecurityConfiguration in the *Amazon EMR API Reference*.

`Name`

The name of the security configuration. For a list of valid parameters for encryption settings, see AWS CLI Security Configuration JSON Reference in the *Amazon EMR Release Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SecurityConfiguration`

The security configuration details in JSON format.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the security configuration name, such as `mySecurityConfiguration`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example enables both in-transit data encryption and local disk encryption, as well as specifying Kerberos attributes. For additional encryption configuration examples, see Creating a Security Configuration Using the AWS CLI in the *Amazon EMR Release Guide*.

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "securityConfiguration": {
            "Type": "AWS::EMR::SecurityConfiguration",
            "Properties": {
                "SecurityConfiguration": {
                    "EncryptionConfiguration": {
                        "EnableInTransitEncryption": true,
                        "EnableAtRestEncryption": true,
                        "InTransitEncryptionConfiguration": {
                            "TLSCertificateConfiguration": {
                                "CertificateProviderType": "PEM",
                                "S3Object": "arn:aws:s3:::MyConfigStore/artifacts/
MyCerts.zip"
                            }
                        },
                        "AtRestEncryptionConfiguration": {
                            "S3EncryptionConfiguration": {
                                "EncryptionMode": "SSE-KMS",
                                "AwsKmsKey": "arn:aws:kms:us-

              CrossRealmTrustConfiguration:
                Realm: AD.DOMAIN.COM
                Domain: ad.domain.com
                AdminServer: ad.domain.com
                KdcServer: ad.domain.com
```

AWS::EMR::Step

The `AWS::EMR::Step` resource creates a unit of work (a job flow step) that you submit to an Amazon EMR (Amazon EMR) cluster. The job flow step contains instructions for processing data on the cluster.

> **Note**
> You can't delete work flow steps. During a stack update, if you remove a step, AWS CloudFormation takes no action.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::EMR::Step",
  "Properties" : {
    "ActionOnFailure" : String,
    "HadoopJarStep" : HadoopJarStepConfig,
    "JobFlowId" : String,
    "Name" : String
  }
}
```

YAML

```
Type: AWS::EMR::Step
Properties:
  ActionOnFailure: String
```

```
  HadoopJarStep:
    HadoopJarStepConfig
  JobFlowId: String
  Name: String
```

Properties

`ActionOnFailure`

The action to take if the job flow step fails. Currently, AWS CloudFormation supports `CONTINUE` and `CANCEL_AND_WAIT`.

- `CANCEL_AND_WAIT`: If the step fails, cancel the remaining steps. If the cluster has auto-terminate disabled, the cluster will not terminate.

  `CONTINUE`: If the step fails, continue to the next step.

For more information, see Managing Cluster Termination in the *Amazon EMR Management Guide*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`HadoopJarStep`

The JAR file that includes the main function that Amazon EMR executes.

Required: Yes

Type: Amazon EMR Step HadoopJarStepConfig (p. 1570)

Update requires: Replacement (p. 121)

`JobFlowId`

The ID of a cluster in which you want to run this job flow step.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Name`

A name for the job flow step.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the step ID, such as `s-1A2BC3D4EFG56`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a step that submits work to the `TestCluster` cluster. The step runs the `pi` program in the `hadoop-mapreduce-examples-2.6.0.jar` file with 5 maps and 10 samples, specified in the `Args` property.

JSON

```
"TestStep": {
  "Type": "AWS::EMR::Step",
  "Properties": {
    "ActionOnFailure": "CONTINUE",
    "HadoopJarStep": {
      "Args": [
        "5",
        "10"
      ],
      "Jar": "s3://emr-cfn-test/hadoop-mapreduce-examples-2.6.0.jar",
      "MainClass": "pi"
    },
    "Name": "TestStep",
    "JobFlowId": {
      "Ref": "TestCluster"
    }
  }
}
```

YAML

```
TestStep:
  Type: AWS::EMR::Step
  Properties:
    ActionOnFailure: "CONTINUE"
    HadoopJarStep:
      Args:
        - "5"
        - "10"
      Jar: "s3://emr-cfn-test/hadoop-mapreduce-examples-2.6.0.jar"
      MainClass: "pi"
    Name: "TestStep"
    JobFlowId:
      Ref: "TestCluster"
```

Amazon EMR Step HadoopJarStepConfig

`HadoopJarStepConfig` is a property of the AWS::EMR::Step (p. 1568) resource that specifies a JAR file and runtime settings that Amazon EMR (Amazon EMR) executes.

Syntax

JSON

```
{
  "Args" : [ String, ... ],
  "Jar" : String,
  "MainClass" : String,
  "StepProperties" : [ KeyValue, ... ]
}
```

YAML

```
Args:
  - String
Jar: String
MainClass: String
StepProperties:
  - KeyValue
```

Properties

`Args`

A list of command line arguments passed to the JAR file's main function when the function is executed.

Required: No

Type: List of String values

`Jar`

A path to the JAR file that Amazon EMR runs for the job flow step.

Required: Yes

Type: String

`MainClass`

The name of the main class in the specified JAR file. If you don't specify a value, you must specify a main class in the JAR file's manifest file.

Required: No

Type: String

`StepProperties`

A list of Java properties that are set when the job flow step runs. You can use these properties to pass key-value pairs to your main function in the JAR file.

Required: No

Type: List of Amazon EMR Step KeyValue (p. 1571)

Amazon EMR Step KeyValue

`KeyValue` is a property of the Amazon EMR Step HadoopJarStepConfig (p. 1570) property that specifies key-value pairs, which are passed to a JAR file that Amazon EMR (Amazon EMR) executes.

Syntax

JSON

```
{
  "Key" : String,
  "Value" : String
}
```

YAML

```
Key: String
Value: String
```

Properties

`Key`

The unique identifier of a key-value pair.

Required: No

Type: String

`Value`

The value part of the identified key.

Required: No

Type: String

Amazon GameLift Resource Types Reference

This section contains reference information for all Amazon GameLift resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::GameLift::data-type-name
```

Topics

- AWS::GameLift::Alias (p. 1572)
- AWS::GameLift::Build (p. 1575)
- AWS::GameLift::Fleet (p. 1578)

AWS::GameLift::Alias

The `AWS::GameLift::Alias` resource creates an alias for an Amazon GameLift (GameLift) fleet, which you can use to anonymize your fleet. You can reference the alias instead of a specific fleet when you create game sessions. For more information, see the CreateAlias action in the *Amazon GameLift API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::GameLift::Alias",
  "Properties" : {
    "Name" : String,
    "Description" : String,
```

```
    "RoutingStrategy" : RoutingStrategy (p. 1574)
  }
}
```

YAML

```
Type: AWS::GameLift::Alias
Properties:
  Name: String
  Description: String
  RoutingStrategy:
    RoutingStrategy (p. 1574)
```

Properties

`Description`

Information that helps you identify the purpose of this alias.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

An identifier to associate with this alias. Alias names don't need to be unique.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoutingStrategy`

A routing configuration that specifies where traffic is directed for this alias, such as to a fleet or to a message.

Required: Yes

Type: Amazon GameLift Alias RoutingStrategy (p. 1574)

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the alias ID, such as `myalias-a01234b56-7890-1de2-f345-g67h8i901j2k`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a terminal alias named `TerminalAlias` with a generic terminal message.

JSON

```
"AliasResource": {
```

```
  "Type": "AWS::GameLift::Alias",
  "Properties": {
    "Name": "TerminalAlias",
    "Description": "A terminal alias",
    "RoutingStrategy": {
      "Type": "TERMINAL",
      "Message": "Terminal routing strategy message"
    }
  }
}
```

YAML

```
AliasResource:
  Type: AWS::GameLift::Alias
  Properties:
    Name: "TerminalAlias"
    Description: "A terminal alias"
    RoutingStrategy:
      Type: "TERMINAL"
      Message: "Terminal routing strategy message"
```

Amazon GameLift Alias RoutingStrategy

`RoutingStrategy` is a property of the AWS::GameLift::Alias (p. 1572) resource that configures the routing strategy for an Amazon GameLift (GameLift) alias. For more information, see the RoutingStrategy data type in the *Amazon GameLift API Reference*.

Syntax

JSON

```
{
  "FleetId" : String,
  "Message" : String,
  "Type" : String
}
```

YAML

```
FleetId: String
Message: String
Type: String
```

Properties

`FleetId`

A unique identifier of a GameLift fleet to associate with the alias.

Required: Conditional. If you specify `SIMPLE` for the `Type` property, you must specify this property.

Type: String

`Message`

A text message that GameLift displays for the `Terminal` routing type.

Required: Conditional. If you specify `TERMINAL` for the `Type` property, you must specify this property.

Type: String

`Type`

The type of routing strategy. For the `SIMPLE` type, traffic is routed to an active GameLift fleet. For the `Terminal` type, GameLift returns an exception with the message that you specified in the `Message` property.

Required: Yes

Type: String

AWS::GameLift::Build

The `AWS::GameLift::Build` resource creates a build that includes all of the components to run your game server in an Amazon GameLift (GameLift) fleet.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::GameLift::Build",
  "Properties" : {
    "Name" : String,
    "StorageLocation" : StorageLocation (p. 1577),
    "Version" : String
  }
}
```

YAML

```
Type: AWS::GameLift::Build
Properties:
  Name: String
  StorageLocation:
    StorageLocation (p. 1577)
  Version: String
```

Properties

`Name`

An identifier to associate with this build. Build names don't need to be unique.

Required: No

Type: String

Update requires: No interruption (p. 120)

`StorageLocation`

The Amazon Simple Storage Service (Amazon S3) location where your build package files are located.

Required: No, but we recommend that you specify a location. If you don't specify this property, you must manually upload your build package files to GameLift.

Type: Amazon GameLift Build StorageLocation (p. 1577)

Update requires: Replacement (p. 121)

`Version`

A version to associate with this build. Version is useful if you want to track updates to your build package files. Versions don't need to be unique.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the build ID, such as `mybuild-a01234b56-7890-1de2-f345-g67h8i901j2k`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a GameLift build named `MyGameServerBuild`. The build package is located in an S3 bucket, specified by the `S3Bucket` and `S3Key` input parameters. The example also creates the AWS Identity and Access Management (IAM) role that GameLift assumes so that it has permissions to download the build package files.

JSON

```
"BuildResource": {
  "Type": "AWS::GameLift::Build",
  "Properties": {
    "Name": "MyGameServerBuild",
    "Version": "v15",
    "StorageLocation": {
      "Bucket": "mybucket",
      "Key": "buildpackagefiles/",
      "RoleArn": { "Fn::GetAtt": [ "IAMRole", "Arn" ] }
    }
  }
},
"IAMRole": {
  "Type": "AWS::IAM::Role",
  "Properties": {
    "AssumeRolePolicyDocument": {
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": { "Service": [ "gamelift.amazonaws.com" ] },
          "Action": [ "sts:AssumeRole" ]
        }
      ]
    },
    "Path": "/",
    "Policies": [
```

```
      {
        "PolicyName": "gamelift-s3-access-policy",
        "PolicyDocument": {
          "Version": "2012-10-17",
          "Statement": [
            {
              "Effect": "Allow",
              "Action": [ "s3:GetObject" ],
              "Resource": [ "arn:aws:s3:::mybucket/*" ]
            }
          ]
        }
      }
    ]
  }
}
```

YAML

```
BuildResource:
  Type: AWS::GameLift::Build
  Properties:
    Name: "MyGameServerBuild"
    Version: "v15"
    StorageLocation:
      Bucket: "mybucket"
      Key: "buildpackagefiles/"
      RoleArn:
        Fn::GetAtt:
          - "IAMRole"
          - "Arn"
IAMRole:
  Type: AWS::IAM::Role
  Properties:

      Version: "2012-10-17"
      Statement:
        -
          Effect: "Allow"
          Principal:
            Service:
              - "gamelift.amazonaws.com"
          Action:
            - "sts:AssumeRole"
    Path: "/"
    Policies:
      -
        PolicyName: "gamelift-s3-access-policy"
        PolicyDocument:
          Version: "2012-10-17"
          Statement:
            -
              Effect: "Allow"
              Action:
                - "s3:GetObject"
              Resource:
                - "arn:aws:s3:::mybucket/*"
```

Amazon GameLift Build StorageLocation

`StorageLocation` is a property of the AWS::GameLift::Build (p. 1575) resource that specifies the location of an Amazon GameLift (GameLift) build package files, such as the game server binaries. For more information, see Uploading a Build to Amazon GameLift in the *Amazon GameLift Developer Guide*.

Syntax

JSON

```
{
  "Bucket" : String,
  "Key" : String,
  "RoleArn" : String
}
```

YAML

```
Bucket: String
Key: String
RoleArn: String
```

Properties

`Bucket`

The S3 bucket where the GameLift build package files are stored.

Required: Yes

Type: String

`Key`

The prefix (folder name) where the GameLift build package files are located.

Required: Yes

Type: String

`RoleArn`

An AWS Identity and Access Management (IAM) role Amazon Resource Name (ARN) that GameLift can assume to retrieve the build package files from Amazon Simple Storage Service (Amazon S3).

Required: Yes

Type: String

AWS::GameLift::Fleet

The `AWS::GameLift::Fleet` resource creates an Amazon GameLift (GameLift) fleet to host game servers. A fleet is a set of EC2 instances, each of which is a host in the fleet. For more information, see the CreateFleet action in the *Amazon GameLift API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Type" : "AWS::GameLift::Fleet",
  "Properties" : {
    "BuildId" : String,
    "Description" : String,
    "DesiredEC2Instances" : Integer,
    "EC2InboundPermissions" : [ EC2InboundPermission (p. 1582), ... ],
    "EC2InstanceType" : String,
    "LogPaths" : [ String, ... ],
    "MaxSize" : Integer,
    "MinSize" : Integer,
    "Name" : String,
    "ServerLaunchParameters" : String,
    "ServerLaunchPath" : String
  }
}
```

YAML

```
Type: AWS::GameLift::Fleet
Properties:
  BuildId: String
  Description: String
  DesiredEC2Instances: Integer
  EC2InboundPermissions:
    - EC2InboundPermission (p. 1582)
  EC2InstanceType: String
  LogPaths:
    [ String, ... ]
  MaxSize: Integer
  MinSize: Integer
  Name: String
  ServerLaunchParameters: String
  ServerLaunchPath: String
```

Properties

`BuildId`

The unique identifier for the build that you want to use with this fleet.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Description`

Information that helps you identify the purpose of this fleet.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DesiredEC2Instances`

The number of EC2 instances that you want in this fleet.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

`EC2InboundPermissions`

The incoming traffic, expressed as IP ranges and port numbers, that is permitted to access the game server. If you don't specify values, no traffic is permitted to your game servers.

Required: No

Type: List of Amazon GameLift Fleet EC2InboundPermission (p. 1582)

Update requires: No interruption (p. 120)

`EC2InstanceType`

The type of EC2 instances that the fleet uses. EC2 instance types define the CPU, memory, storage, and networking capacity of the fleet's hosts. For more information about the instance types that are supported by GameLift, see the EC2InstanceType parameter in the *Amazon GameLift API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`LogPaths`

The path to game-session log files that are generated by your game server, with the slashes (\) escaped. After a game session has been terminated, GameLift captures and stores the logs in an S3 bucket.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`MaxSize`

The maximum number of EC2 instances that you want to allow in this fleet. By default, AWS CloudFormation, sets this property to `1`.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`MinSize`

The minimum number of EC2 instances that you want to allow in this fleet. By default, AWS CloudFormation, sets this property to `0`.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Name`

An identifier to associate with this fleet. Fleet names don't need to be unique.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ServerLaunchParameters`

The parameters that are required to launch your game server. Specify these parameters as a string of command-line parameters, such as `+sv_port 33435 +start_lobby`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ServerLaunchPath`

The location of your game server that GameLift launches. You must escape the slashes (`\`) and use the following pattern: `C:\\game\\`*`launchpath`*. For example, if your game server files are in the `MyGame` folder, the path should be `C:\\game\\MyGame\\server.exe`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the fleet ID, such as `myfleet-a01234b56-7890-1de2-f345-g67h8i901j2k`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a GameLift fleet named `MyGameFleet` with two inbound permissions. The fleet uses a `Ref` intrinsic function to specify a build, which can be declared elsewhere in the same template. For the log path and server launch path, the example uses the escape character (`\`) to escape the slashes (`\`).

JSON

```
"FleetResource": {
  "Type": "AWS::GameLift::Fleet",
  "Properties": {
    "Name": "MyGameFleet",
    "Description": "A fleet for my game",
    "BuildId": { "Ref": "BuildResource" },
    "ServerLaunchPath": "c:\\game\\TestApplicationServer.exe",
    "LogPaths": [
      "c:\\game\\testlog.log",
      "c:\\game\\testlog2.log"
    ],
    "EC2InstanceType": "t2.small",
    "DesiredEC2Instances": "2",
    "EC2InboundPermissions": [
      {
        "FromPort": "1234",
```

```
        "ToPort": "1324",
        "IpRange": "0.0.0.0/24",
        "Protocol": "TCP"
      },
      {
        "FromPort": "1356",
        "ToPort": "1578",
        "IpRange": "192.168.0.0/24",
        "Protocol": "UDP"
      }
    ]
  }
}
```

YAML

```
FleetResource:
  Type: AWS::GameLift::Fleet
  Properties:
    Name: "MyGameFleet"
    Description: "A fleet for my game"
    BuildId:
      Ref: "BuildResource"
    ServerLaunchPath: "c:\\game\\TestApplicationServer.exe"
    LogPaths:
      - "c:\\game\\testlog.log"
      - "c:\\game\\testlog2.log"
    EC2InstanceType: "t2.small"
    DesiredEC2Instances: "2"
    EC2InboundPermissions:
      -
        FromPort: "1234"
        ToPort: "1324"
        IpRange: "0.0.0.0/24"
        Protocol: "TCP"
      -
        FromPort: "1356"
        ToPort: "1578"
        IpRange: "192.168.0.0/24"
        Protocol: "UDP"
```

Amazon GameLift Fleet EC2InboundPermission

`EC2InboundPermission` is a property of the AWS::GameLift::Fleet (p. 1578) resource that specifies the traffic that is permitted to access your game servers in an Amazon GameLift (GameLift) fleet.

Syntax

JSON

```
{
  "FromPort" : Integer,
  "IpRange" : String,
  "Protocol" : String,
  "ToPort" : Integer
}
```

YAML

```
FromPort: Integer
IpRange: String
```

```
Protocol: String
ToPort: Integer
```

Properties

`FromPort`

The starting value for a range of allowed port numbers. This value must be lower than the `ToPort` value.

Required: Yes

Type: Integer

`IpRange`

The range of allowed IP addresses in CIDR notation.

Required: Yes

Type: String

`Protocol`

The network communication protocol that is used by the fleet. For valid values, see the IpPermission data type in the *Amazon GameLift API Reference*.

Required: Yes

Type: String

`ToPort`

The ending value for a range of allowed port numbers. This value must be higher than the `FromPort` value.

Required: Yes

Type: Integer

AWS Glue Resource Types Reference

This section contains reference information for all AWS Glue resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::Glue::data-type-name
```

Topics

- AWS::Glue::Classifier (p. 1584)
- AWS::Glue::Connection (p. 1588)
- AWS::Glue::Crawler (p. 1592)
- AWS::Glue::Database (p. 1601)
- AWS::Glue::DevEndpoint (p. 1604)

- AWS::Glue::Job (p. 1606)
- AWS::Glue::Partition (p. 1612)
- AWS::Glue::Table (p. 1621)
- AWS::Glue::Trigger (p. 1632)

AWS::Glue::Classifier

The `AWS::Glue::Classifier` resource creates an AWS Glue classifier that categorizes data sources and specifies schemas. For more information, see Adding Classifiers to a Crawler and Classifier Structure in the *AWS Glue Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Glue::Classifier",
  "Properties" : {
    "GrokClassifier" : GrokClassifier (p. 1585)
    "JsonClassifier" : JsonClassifier (p. 1586)
    "XMLClassifier" : XMLClassifier (p. 1587)
  }
}
```

YAML

```
Type: AWS::Glue::Classifier
Properties:
  GrokClassifier:
    GrokClassifier (p. 1585)
  JsonClassifier:
    JsonClassifier (p. 1586)
  XMLClassifier:
    XMLClassifier (p. 1587)
```

Properties

`GrokClassifier`

A classifier that uses `grok`.

Required: No

Type: GrokClassifier (p. 1585)

Update requires: No interruption (p. 120)

`JsonClassifier`

A classifier for JSON content.

Required: No

Type: JsonClassifier (p. 1586)

Update requires: No interruption (p. 120)

`XMLClassifier`

A classifier for XML content.

Required: No

Type: XMLClassifier (p. 1587)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS Glue Classifier GrokClassifier

The `GrokClassifier` property type specifies an AWS Glue classifier that uses `grok`.

`GrokClassifier` is a property of the AWS::Glue::Classifier (p. 1584) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "CustomPatterns" : String,
  "GrokPattern" : String,
  "Classification" : String,
  "Name" : String
}
```

YAML

```
CustomPatterns: String
GrokPattern: String
Classification: String
Name: String
```

Properties

For more information, see GrokClassifier Structure in the *AWS Glue Developer Guide*.

`CustomPatterns`

Custom grok patterns that are used by this classifier. It must match the URI address multi-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`GrokPattern`

The grok pattern that's used by this classifier. It must match the Logstash grok string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\t]*`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Classification`

The data form that the classifier matches—such as Twitter, JSON, or Omniture logs.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the classifier. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: Replacement (p. 121)

AWS Glue Classifier JsonClassifier

The `JsonClassifier` property type specifies an AWS Glue classifier for JSON content.

`JsonClassifier` is a property of the AWS::Glue::Classifier (p. 1584) resource type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "JsonPath" : String,
  "Name" : String
}
```

YAML

```
JsonPath: String
Name: String
```

Properties

`JsonPath`

A JsonPath string defining the JSON data for the classifier to classify. AWS Glue supports a subset of JsonPath, as described in Writing JsonPath Custom Classifiers.

Required: Yes

Type: String

Update requires: No Interruption (p. 120)

`Name`

The name of the classifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

See Also

- JsonClassifier Structure in the *AWS Glue Developer Guide*

AWS Glue Classifier XMLClassifier

The `XMLClassifier` property type specifies specifies an AWS Glue classifier for XML content.

`XMLClassifier` is a property of the AWS::Glue::Classifier (p. 1584) resource type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Classification" : String,
  "Name" : String,
  "RowTag" : String
}
```

YAML

```
Classification: String
Name: String
RowTag: String
```

Properties

`Classification`

An identifier of the data format that the classifier matches.

Required: Yes

Type: String

Update requires: No Interruption (p. 120)

`Name`

The name of the classifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`RowTag`

The XML tag designating the element that contains each record in an XML document being parsed. Note that this cannot identify a self-closing element (closed by />). An empty row element that contains only attributes can be parsed as long as it ends with a closing tag. For example, `<row item_a="A" item_b="B"></row>` is okay, but `<row item_a="A" item_b="B" />` is not.

Required: Yes

Type: String

Update requires: No Interruption (p. 120)

See Also

- XMLClassifier Structure in the *AWS Glue Developer Guide*

AWS::Glue::Connection

The `AWS::Glue::Connection` resource specifies an AWS Glue connection to a data source. For more information, see Adding a Connection to Your Data Store and Connection Structure in the *AWS Glue Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Glue::Connection",
  "Properties" : {
    "ConnectionInput" : ConnectionInput (p. 1589),
    "CatalogId" : String
  }
}
```

YAML

```
Type: AWS::Glue::Connection
Properties:
  ConnectionInput:
    ConnectionInput (p. 1589)
  CatalogId: String
```

Properties

`ConnectionInput`

The connection that you want to create.

Required: Yes

Type: ConnectionInput (p. 1589)

Update requires: No interruption (p. 120)

`CatalogId`

The ID of the data catalog to create the catalog object in. Currently, this should be the AWS account ID.

> **Note**
> To specify the account ID, you can use the `Ref` intrinsic function with the `AWS::AccountId` pseudo parameter—for example `!Ref AWS::AccountId`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the `ConnectionInput` name.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS Glue Connection ConnectionInput

The `ConnectionInput` property type specifies the AWS Glue connection to create.

`ConnectionInput` is a property of the AWS::Glue::Connection (p. 1588) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Description" : String,
  "ConnectionType" : String,
  "MatchCriteria" : [ String, ... ],
  "PhysicalConnectionRequirements" : PhysicalConnectionRequirements (p. 1591),
  "ConnectionProperties" : JSON object,
  "Name" : String
}
```

YAML

```
Description: String
ConnectionType: String
MatchCriteria:
  - String
PhysicalConnectionRequirements:
  PhysicalConnectionRequirements (p. 1591)
ConnectionProperties: JSON object
Name: String
```

Properties

For more information, see ConnectionInput Structure in the *AWS Glue Developer Guide*.

`Description`

The description of the connection.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ConnectionType`

The type of the connection. Valid values are `JDBC` or `SFTP`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`MatchCriteria`

A list of UTF-8 strings that specify the criteria that you can use in selecting this connection.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`PhysicalConnectionRequirements`

A map of physical connection requirements that are needed to make the connection, such as VPC and SecurityGroup.

Required: Yes

Type: PhysicalConnectionRequirements (p. 1591)

Update requires: No interruption (p. 120)

`ConnectionProperties`

UTF-8 string–to–UTF-8 string key-value pairs that specify the parameters for this connection.

Required: Yes

Type: JSON object

Update requires: No interruption (p. 120)

`Name`

The name of the connection.

Required: No

Type: String

Update requires: Replacement (p. 121)

AWS Glue Connection PhysicalConnectionRequirements

The `PhysicalConnectionRequirements` property type specifies the physical connection requirements that are needed to make an AWS Glue connection, such as VPC and SecurityGroup.

`PhysicalConnectionRequirements` is a property of the AWS Glue Connection ConnectionInput (p. 1589) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "AvailabilityZone" : String,
  "SecurityGroupIdList" : [ String, ... ],
  "SubnetId" : String
}
```

YAML

```
AvailabilityZone: String
SecurityGroupIdList:
  - String
SubnetId: String
```

Properties

For more information, see PhysicalConnectionRequirements Structure in the *AWS Glue Developer Guide*.

`AvailabilityZone`

The connection's Availability Zone. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`SecurityGroupIdList`

A list of UTF-8 strings that specify the security group IDs that are used by the connection.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`SubnetId`

The subnet ID that's used by the connection. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

AWS::Glue::Crawler

The `AWS::Glue::Crawler` resource specifies an AWS Glue crawler. For more information, see Cataloging Tables with a Crawler and Crawler Structure in the *AWS Glue Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Glue::Crawler",
  "Properties" : {
    "Role" : String,
    "Classifiers" : [ String, ... ],
    "Configuration" : String,
    "Description" : String,
    "SchemaChangePolicy" : SchemaChangePolicy (p. 1600),
    "Schedule" : Schedule (p. 1599),
    "DatabaseName" : String,
    "Targets" : Targets (p. 1601),
    "TablePrefix" : String,
    "Name" : String
  }
}
```

YAML

```
Type: AWS::Glue::Crawler
Properties:
  Role: String
  Classifiers:
    - String
  Configuration: String
  Description: String
  SchemaChangePolicy:
    SchemaChangePolicy (p. 1600)
  Schedule:
    Schedule (p. 1599)
  DatabaseName: String
  Targets:
    Targets (p. 1601)
  TablePrefix: String
  Name: String
```

Properties

`Role`

The Amazon Resource Name (ARN) of an IAM role that's used to access customer resources, such as Amazon S3 data.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Classifiers`

A list of UTF-8 strings that specify the custom classifiers that are associated with the crawler.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Configuration`

Crawler configuration information. This versioned JSON string allows users to specify aspects of a crawler's behavior. For more information, see Configuring a Crawler..

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

A description of the crawler and where it should be used. It must match the URI address multi-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`SchemaChangePolicy`

The policy that specifies update and delete behaviors for the crawler.

Required: No

Type: SchemaChangePolicy (p. 1600)

Update requires: No interruption (p. 120)

`Schedule`

The schedule for the crawler.

Required: No

Type: Schedule (p. 1599)

Update requires: No interruption (p. 120)

`DatabaseName`

The name of the database where the crawler's output is stored.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Targets`

The crawler targets.

Required: Yes

Type: Targets (p. 1601)

Update requires: No interruption (p. 120)

`TablePrefix`

The table prefix that's used for catalog tables that are created.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the crawler. Must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following example creates a crawler for an Amazon S3 target.

JSON

```
{
    "Description": "AWS Glue Crawler Test",
    "Resources": {
        "MyRole": {
            "Type": "AWS::IAM::Role",
            "Properties": {
                "AssumeRolePolicyDocument": {
                    "Version": "2012-10-17",
                    "Statement": [
                        {
                            "Effect": "Allow",
                            "Principal": {
                                "Service": [
                                    "glue.amazonaws.com"
                                ]
                            },
                            "Action": [
                                "sts:AssumeRole"
                            ]
                        }
                    ]
                },
```

```
                "Path": "/",
                "Policies": [
                    {
                        "PolicyName": "root",

```

Crawler Configuration

The following example specifies the crawler configuration that controls a crawler's behavior.

```
{
"Type" : "AWS::Glue::Crawler",
"Properties" : {
"Role" : "role1",
"Classifiers" : [ ],
"Description" : "example classifier",
"SchemaChangePolicy" : "",
"Schedule" : Schedule,
"DatabaseName" : "test",
"Targets" : [],
"TablePrefix" : "test-",
"Name" : "my-crawler",
"Configuration" : "{\"Version\":1.0,\"CrawlerOutput\":{\"Partitions\":
{\"AddOrUpdateBehavior\":\"InheritFromTable\"},\"Tables\":{\"AddOrUpdateBehavior\":
\"MergeNewColumns\"}}}"
}
```

AWS Glue Crawler JdbcTarget

The `JdbcTarget` property type specifies a JDBC target for an AWS Glue crawl.

The `JdbcTargets` property of the Targets (p. 1601) property type contains a list of `JdbcTarget` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ConnectionName" : String,
  "Path" : String,
  "Exclusions" : [ String, ... ]
}
```

YAML

```
ConnectionName: String
Path: String
Exclusions:
  - String
```

Properties

For more information, see JdbcTarget Structure in the *AWS Glue Developer Guide*.

`ConnectionName`

The name of the connection to use for the JDBC target.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Path`

The path of the JDBC target.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Exclusions`

A list of UTF-8 strings that specify the items to exclude from the crawl.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

AWS Glue Crawler S3Target

The `S3Target` property type specifies an Amazon S3 target for an AWS Glue crawl.

The `S3Targets` property of the Targets (p. 1601) property type contains a list of `S3Target` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Path" : String,
  "Exclusions" : [ String, ... ]
}
```

YAML

```
Path: String
Exclusions:
  - String
```

Properties

For more information, see S3Target Structure in the *AWS Glue Developer Guide*.

`Path`

The path to the Amazon S3 target.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Exclusions`

A list of UTF-8 strings that specify the Amazon S3 objects to exclude from the crawl.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

AWS Glue Crawler Schedule

The `Schedule` property type schedules an event for an AWS Glue crawler using a `cron` statement.

`Schedule` is a property of the AWS::Glue::Crawler (p. 1592) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ScheduleExpression" : String
}
```

YAML

```
ScheduleExpression: String
```

Properties

For more information, see Schedule Structure in the *AWS Glue Developer Guide*.

`ScheduleExpression`

A `cron` expression that you can use as an Amazon CloudWatch Events event to schedule something. For example, to run something every day at 12:15 UTC, you would specify: `cron(15 12 * * ? *)`.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Glue Crawler SchemaChangePolicy

The `SchemaChangePolicy` property type specifies update and delete behaviors for an AWS Glue crawler.

`SchemaChangePolicy` is a property of the AWS::Glue::Crawler (p. 1592) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "UpdateBehavior" : String,
  "DeleteBehavior" : String
}
```

YAML

```
UpdateBehavior: String
DeleteBehavior: String
```

Properties

For more information, see SchemaChangePolicy Structure in the *AWS Glue Developer Guide*.

`UpdateBehavior`

The update behavior. Valid values are `LOG` or `UPDATE_IN_DATABASE`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DeleteBehavior`

The deletion behavior. Valid values are `LOG`, `DELETE_FROM_DATABASE`, or `DEPRECATE_IN_DATABASE`.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Glue Crawler Targets

The `Targets` property type specifies AWS Glue crawler targets.

`Targets` is a property of the AWS::Glue::Crawler (p. 1592) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "S3Targets" : [ S3Target (p. 1598), ... ],
  "JdbcTargets" : [ JdbcTarget (p. 1597), ... ]
}
```

YAML

```
S3Targets:
  - S3Target (p. 1598)
JdbcTargets:
  - JdbcTarget (p. 1597)
```

Properties

For more information, see CrawlerTargets Structure in the *AWS Glue Developer Guide*.

`S3Targets`

The Amazon S3 crawler targets.

Required: No

Type: List of S3Target (p. 1598)

Update requires: No interruption (p. 120)

`JdbcTargets`

The JDBC crawler targets.

Required: No

Type: List of JdbcTarget (p. 1597)

Update requires: No interruption (p. 120)

AWS::Glue::Database

The `AWS::Glue::Database` resource specifies a logical grouping of tables in AWS Glue. For more information, see Defining a Database in Your Data Catalog and Database Structure in the *AWS Glue Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Glue::Database",
  "Properties" : {
    "DatabaseInput" : DatabaseInput (p. 1602),
    "CatalogId" : String
  }
}
```

YAML

```
Type: AWS::Glue::Database
Properties:
  DatabaseInput:
    DatabaseInput (p. 1602)
  CatalogId: String
```

Properties

`DatabaseInput`

The metadata of the database.

Required: Yes

Type: DatabaseInput (p. 1602)

Update requires: No interruption (p. 120)

`CatalogId`

The ID of the data catalog to create the catalog object in. Currently, this should be the AWS account ID.

> **Note**
> To specify the account ID, you can use the `Ref` intrinsic function with the `AWS::AccountId` pseudo parameter—for example `!Ref AWS::AccountId`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the `DatabaseInput` name.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS Glue Database DatabaseInput

The `DatabaseInput` property type specifies the metadata that is used to create or update an AWS Glue database.

`DatabaseInput` is a property of the AWS::Glue::Database (p. 1601) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "LocationUri" : String,
  "Description" : String,
  "Parameters" : JSON object,
  "Name" : String
}
```

YAML

```
LocationUri: String
Description: String
Parameters: JSON object
Name: String
```

Properties

For more information, see DatabaseInput Structure in the *AWS Glue Developer Guide*.

`LocationUri`

The location of the database (for example, an HDFS path). It must match the URI address multi-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the database. It must match the URI address multi-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Parameters`

UTF-8 string–to–UTF-8 string key-value pairs that specify the properties that are associated with the database.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`Name`

The name of the database. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: Replacement (p. 121)

AWS::Glue::DevEndpoint

The `AWS::Glue::DevEndpoint` resource specifies a development endpoint where a developer can remotely debug ETL scripts for AWS Glue. For more information, see DevEndpoint Structure in the *AWS Glue Developer Guide*.

Topics

- Syntax (p. 1604)
- Properties (p. 1604)
- See Also (p. 1606)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Glue::DevEndpoint",
  "Properties" : {
    "EndpointName" : String,
    "ExtraJarsS3Path" : String,
    "ExtraPythonLibsS3Path" : String,
    "NumberOfNodes" : Integer,
    "PublicKey" : String,
    "RoleArn" : String,
    "SecurityGroupIds" : [ String, ... ],
    "SubnetId" : String
  }
}
```

YAML

```
Type: AWS::Glue::DevEndpoint
Properties:
  EndpointName: String
  ExtraJarsS3Path: String
  ExtraPythonLibsS3Path: String
  NumberOfNodes: Integer
  PublicKey: String
  RoleArn: String
  SecurityGroupIds:
    - String
  SubnetId: String
```

Properties

`EndpointName`

The name of the endpoint.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ExtraJarsS3Path`

The path to one or more Java Jars in an Amazon S3 bucket to load in your endpoint.

> **Note**
> You can currently use only pure Java/Scala libraries on a DevEndpoint.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ExtraPythonLibsS3Path`

The path to one or more Python libraries in an Amazon S3 bucket to load in your endpoint.

> **Note**
> You can currently use only pure Python libraries on a DevEndpoint. Libraries that rely on C extensions, such as the pandas Python data analysis library, aren't supported yet.

Required: No

Type: String

Update requires: No interruption (p. 120)

`NumberOfNodes`

The number of nodes that the endpoint uses.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`PublicKey`

The public key for the endpoint to use for authentication.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoleArn`

The Amazon Resource Name (ARN) of the IAM role for the endpoint. It must match the AWS ARN string pattern: `arn:aws:iam::\d{12}:role/.*`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`SecurityGroupIds`

A list of UTF-8 strings that specify the security group IDs for the endpoint.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SubnetId`

The subnet ID for the endpoint.

Required: No

Type: String

Update requires: No interruption (p. 120)

- DevEndpoint Structure in the *AWS Glue Developer Guide*

AWS::Glue::Job

The `AWS::Glue::Job` resource specifies an AWS Glue job in the data catalog. For more information, see Adding Jobs in AWS Glue and Job Structure in the *AWS Glue Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Glue::Job",
  "Properties" : {
    "Role" : String,
    "DefaultArguments" : JSON object,
    "Connections" : ConnectionsList (p. 1610),
    "MaxRetries" : Double,
    "Description" : String,
    "LogUri" : String,
    "Command" : JobCommand (p. 1612),
    "AllocatedCapacity" : Double,
    "ExecutionProperty" : ExecutionProperty (p. 1611),
    "Name" : String
  }
}
```

YAML

```
Type: AWS::Glue::Job
Properties:
  Role: String
  DefaultArguments: JSON object
  Connections:
    ConnectionsList (p. 1610)
```

```
  MaxRetries: Double
  Description: String
  LogUri: String
  Command:
    JobCommand (p. 1612)
  AllocatedCapacity: Double
  ExecutionProperty:
    ExecutionProperty (p. 1611)
  Name: String
```

Properties

`Role`

The role that's associated with the job.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`DefaultArguments`

UTF-8 string–to–UTF-8 string key-value pairs that specify the default parameters for the job.

You can specify arguments here that your own job-execution script consumes, as well as arguments that AWS Glue itself consumes. For information about how to specify and consume your own Job arguments, see the Passing and Accessing Python Parameters in AWS Glue in the *AWS Glue Developer Guide*.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`Connections`

The connections that are used by the job.

Required: No

Type: ConnectionsList (p. 1610)

Update requires: No interruption (p. 120)

`MaxRetries`

The maximum number of times to retry this job if it fails.

Required: No

Type: Double

Update requires: No interruption (p. 120)

`Description`

The description of the job.

Required: No

Type: String

Update requires: No interruption (p. 120)

`LogUri`

The location of the logs for the job.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Command`

The code that executes a job.

Required: Yes

Type: JobCommand (p. 1612)

Update requires: No interruption (p. 120)

`AllocatedCapacity`

The number of capacity units that are allocated to this job.

Required: No

Type: Double

Update requires: No interruption (p. 120)

`ExecutionProperty`

The execution property of the job, which specifies the maximum number of concurrent runs that are allowed for the job.

Required: No

Type: ExecutionProperty (p. 1611)

Update requires: No interruption (p. 120)

`Name`

The name of the job. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following example creates a job with an associated role.

JSON

```
{
  "Description": "AWS Glue Job Test",
  "Resources": {
    "MyJobRole": {
      "Type": "AWS::IAM::Role",
      "Properties": {
        "AssumeRolePolicyDocument": {
          "Version": "2012-10-17",
          "Statement": [
            {
              "Effect": "Allow",
              "Principal": {
                "Service": [
                  "glue.amazonaws.com"
                ]
              },
              "Action": [
                "sts:AssumeRole"
              ]
            }
          ]
        },
        "Path": "/",
        "Policies": [
          {
            "PolicyName": "root",
            "PolicyDocument": {
              "Version": "2012-10-17",
              "Statement": [
                {
                  "Effect": "Allow",
                  "Action": "*",
                  "Resource": "*"
                }
              ]
            }
          }
        ]
      }
    },
    "MyJob": {
      "Type": "AWS::Glue::Job",
      "Properties": {
        "Command": {
          "Name": "glueetl",
          "ScriptLocation": "s3://aws-glue-scripts//prod-job1"
        },
        "DefaultArguments": {
          "--job-bookmark-option": "job-bookmark-enable"
        },
        "ExecutionProperty": {
          "MaxConcurrentRuns": 2
        },
        "MaxRetries": 0,
        "Name": "cf-job1",
        "Role": {
          "Ref": "MyJobRole"
        }
```

```
      }
    }
  }
}
```

YAML

```
---
Description: "AWS Glue Job Test"
Resources:

      Name: cf-job1
      Role: !Ref MyJobRole
```

AWS Glue Job ConnectionsList

The `ConnectionsList` property type specifies the connections that are used by an AWS Glue job.

`ConnectionsList` is the property type for the `Connections` property of the AWS::Glue::Job (p. 1606) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Connections" : [ String, ... ]
}
```

YAML

```
Connections:
  - String
```

Properties

For more information, see ConnectionsList Structure in the *AWS Glue Developer Guide*.

`Connections`

A list of UTF-8 strings that specifies the connections that are used by the job.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

AWS Glue Job ExecutionProperty

The `ExecutionProperty` property type specifies the maximum number of concurrent runs allowed for an AWS Glue job.

`ExecutionProperty` is a property of the AWS::Glue::Job (p. 1606) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "MaxConcurrentRuns" : Integer
}
```

YAML

```
MaxConcurrentRuns: Integer
```

Properties

For more information, see ExecutionProperty Structure in the *AWS Glue Developer Guide*.

`MaxConcurrentRuns`

The maximum number of concurrent runs that are allowed for the job.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

AWS Glue Job JobCommand

The `JobCommand` property type specifies code that executes an AWS Glue job.

`JobCommand` is the property type for the `Command` property of the AWS::Glue::Job (p. 1606) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ScriptLocation" : String,
  "Name" : String
}
```

YAML

```
ScriptLocation: String
Name: String
```

Properties

For more information, see JobCommand Structure in the *AWS Glue Developer Guide*.

`ScriptLocation`

The location of a script that executes a job.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the job command.

Required: No

Type: String

Valid values: `glueetl`

Update requires: No interruption (p. 120)

AWS::Glue::Partition

The `AWS::Glue::Partition` resource creates an AWS Glue partition, which represents a slice of table data. For more information, see CreatePartition Action and Partition Structure in the *AWS Glue Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Glue::Partition",
  "Properties" : {
    "TableName" : String,
    "DatabaseName" : String,
    "CatalogId" : String,
    "PartitionInput" : PartitionInput (p. 1616)
  }
}
```

YAML

```
Type: AWS::Glue::Partition
Properties:
  TableName: String
  DatabaseName: String
  CatalogId: String
  PartitionInput:
    PartitionInput (p. 1616)
```

Properties

`TableName`

The name of the metadata table to create the partition in.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`DatabaseName`

The name of the catalog database to create the partition in. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`CatalogId`

The ID of the data catalog to create the catalog object in. Currently, this should be the AWS account ID.

> **Note**
> To specify the account ID, you can use the `Ref` intrinsic function with the `AWS::AccountId` pseudo parameter—for example `!Ref AWS::AccountId`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`PartitionInput`

The metadata of the partition.

Required: Yes

Type: PartitionInput (p. 1616)

Update requires: Some interruptions (p. 121)

See Also

- CreatePartition Action in the *AWS Glue Developer Guide*
- Partition Structure in the *AWS Glue Developer Guide*

AWS Glue Partition Column

The `Column` property type specifies a column for an AWS Glue partition.

The `Columns` property of the StorageDescriptor (p. 1619) property type contains a list of `Column` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Comment" : String,
  "Type" : String,
  "Name" : String
}
```

YAML

```
Comment: String
Type: String
Name: String
```

Properties

`Comment`

A free-form text comment. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Type`

The data type of the column data. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the column. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

AWS Glue Partition Order

The `Order` property type specifies the sort order of a column in an AWS Glue partition.

The `SortColumns` property of the StorageDescriptor (p. 1619) property type contains a list of `Order` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Column" : String,
  "SortOrder" : Integer
}
```

YAML

```
Column: String
SortOrder: Integer
```

Properties

`Column`

The name of the column. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`SortOrder`

Indicates whether the column is sorted in ascending order (`1`) or descending order (`0`).

Required: No

Type: Integer

Update requires: No interruption (p. 120)

AWS Glue Partition PartitionInput

The `PartitionInput` property type specifies the metadata that's used to create or update an AWS Glue partition.

`PartitionInput` is a property of the AWS::Glue::Partition (p. 1612) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Parameters" : JSON object,
  "StorageDescriptor" : StorageDescriptor (p. 1619),
  "Values" : [ String, ... ]
}
```

YAML

```
Parameters:
  JSON object
StorageDescriptor:
  StorageDescriptor (p. 1619)
Values:
  - String
```

Properties

`Parameters`

UTF-8 string–to–UTF-8 string key-value pairs that specify the parameters for the partition.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`StorageDescriptor`

Information about the physical storage of the partition.

Required: No

Type: StorageDescriptor (p. 1619)

Update requires: No interruption (p. 120)

`Values`

A list of UTF-8 strings that specify the values of the partition.

Required: Yes

Type: List of String values

Update requires: Replacement (p. 121)

See Also

- PartitionInput in the *AWS Glue Developer Guide*

AWS Glue Partition SerdeInfo

The `SerdeInfo` property type specifies information about a serialization/deserialization program (SerDe), which serves as an extractor and loader for an AWS Glue partition.

`SerdeInfo` is a property of the StorageDescriptor (p. 1619) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Parameters" : JSON object,
  "SerializationLibrary" : String,
  "Name" : String
}
```

YAML

```
Parameters:
  JSON object
SerializationLibrary: String
Name: String
```

Properties

`Parameters`

UTF-8 string–to–UTF-8 string key-value pairs that specify the initialization parameters for the SerDe.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`SerializationLibrary`

The serialization library. This is usually the class that implements the SerDe, such as `org.apache.hadoop.hive.serde2.columnar.ColumnarSerDe`. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the SerDe. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Glue Partition SkewedInfo

The `SkewedInfo` property type specifies skewed values (values that occur with very high frequency) in an AWS Glue partition.

`SkewedInfo` is a property of the StorageDescriptor (p. 1619) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SkewedColumnNames" : [ String, ... ],
  "SkewedColumnValues" : [ String, ... ],
  "SkewedColumnValueLocationMaps" : JSON object
}
```

YAML

```
SkewedColumnNames:
  - String
SkewedColumnValues:
  - String
SkewedColumnValueLocationMaps:
  JSON object
```

Properties

`SkewedColumnNames`

A list of UTF-8 strings that specify the names of columns that contain skewed values.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SkewedColumnValues`

A list of UTF-8 strings that specify values that appear so frequently that they're considered to be skewed.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SkewedColumnValueLocationMaps`

UTF-8 string–to–UTF-8 string key-value pairs that map skewed values to the columns that contain them.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

AWS Glue Partition StorageDescriptor

The `StorageDescriptor` property type describes the physical storage of AWS Glue partition data.

`StorageDescriptor` is a property of the PartitionInput (p. 1616) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "StoredAsSubDirectories" : Boolean,
  "Parameters" : JSON object,
  "BucketColumns" : [ String, ... ],
  "SkewedInfo" : SkewedInfo (p. 1618),
  "InputFormat" : String,
  "NumberOfBuckets" : Integer,
  "OutputFormat" : String,
  "Columns" : [ Column (p. 1614), ... ],
  "SerdeInfo" : SerdeInfo (p. 1617),
  "SortColumns" : [ Order (p. 1615), ... ],
  "Compressed" : Boolean,
  "Location" : String
}
```

YAML

```
StoredAsSubDirectories: Boolean
Parameters:
  JSON object
BucketColumns:
  - String
SkewedInfo:
  SkewedInfo (p. 1618)
InputFormat: String
NumberOfBuckets: Integer
OutputFormat: String
Columns:
  - Column (p. 1614)
SerdeInfo:
  SerdeInfo (p. 1617)
SortColumns:
  - Order (p. 1615)
Compressed: Boolean
Location: String
```

Properties

`StoredAsSubDirectories`

Indicates whether the partition data is stored in subdirectories.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Parameters`

UTF-8 string–to–UTF-8 string key-value pairs that specify user-supplied properties.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`BucketColumns`

A list of UTF-8 strings that specify reducer grouping columns, clustering columns, and bucketing columns in the partition.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SkewedInfo`

Information about values that appear very frequently in a column (skewed values).

Required: No

Type: SkewedInfo (p. 1618)

Update requires: No interruption (p. 120)

`InputFormat`

The input format: `SequenceFileInputFormat` (binary), `TextInputFormat`, or a custom format. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`NumberOfBuckets`

The number of buckets.

Required: Conditional. You must specify this property if the partition contains any dimension columns.

Type: Integer

Update requires: No interruption (p. 120)

`OutputFormat`

The output format: `SequenceFileOutputFormat` (binary), `IgnoreKeyTextOutputFormat`, or a custom format. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Columns`

The columns in the partition.

Required: No

Type: List of Column (p. 1614)

Update requires: No interruption (p. 120)

`SerdeInfo`

Information about a serialization/deserialization program (SerDe), which serves as an extractor and loader.

Required: No

Type: SerdeInfo (p. 1617)

Update requires: No interruption (p. 120)

`SortColumns`

The sort order of each bucket in the partition.

Required: No

Type: List of Order (p. 1615)

Update requires: No interruption (p. 120)

`Compressed`

Indicates whether the data in the partition is compressed.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Location`

The physical location of the partition. By default, this takes the form of the warehouse location, followed by the database location in the warehouse, followed by the partition name. It must match the URI address multi-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS::Glue::Table

The `AWS::Glue::Table` resource specifies tabular data in the AWS Glue data catalog. For more information, see Defining Tables in the AWS Glue Data Catalog and Table Structure in the *AWS Glue Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Glue::Table",
  "Properties" : {
    "TableInput" : TableInput (p. 1630),
    "DatabaseName" : String,
    "CatalogId" : String
  }
}
```

YAML

```
Type: AWS::Glue::Table
Properties:
  TableInput:
    TableInput (p. 1630)
  DatabaseName: String
  CatalogId: String
```

Properties

`TableInput`

The metadata of the table.

Required: Yes

Type: TableInput (p. 1630)

Update requires: Some interruptions (p. 121)

`DatabaseName`

The name of the catalog database for the table. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`CatalogId`

The ID of the data catalog to create the catalog object in. Currently, this should be the AWS account ID.

> **Note**
> To specify the account ID, you can use the `Ref` intrinsic function with the `AWS::AccountId` pseudo parameter—for example `!Ref AWS::AccountId`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the `TableInput` name.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS Glue Table Column

The `Column` property type specifies a column for an AWS Glue table.

The `PartitionKeys` property of the TableInput (p. 1630) property type and the `Columns` property of the StorageDescriptor (p. 1627) property type contain a list of `Column` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Comment" : String,
  "Type" : String,
  "Name" : String
}
```

YAML

```
Comment: String
Type: String
Name: String
```

Properties

For more information, see Column Structure in the *AWS Glue Developer Guide*.

`Comment`

A free-form text comment. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Type`

The data type of the column data. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the column. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

See Also

- Column Structure in the *AWS Glue Developer Guide*

AWS Glue Table Order

The `Order` property type specifies the sort order of a column in an AWS Glue table.

The `SortColumns` property of the StorageDescriptor (p. 1627) property type contains a list of `Order` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Column" : String,
  "SortOrder" : Integer
}
```

YAML

```
Column: String
SortOrder: Integer
```

Properties

For more information, see Order Structure in the *AWS Glue Developer Guide*.

`Column`

The name of the column. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`SortOrder`

Indicates whether the column is sorted in ascending order (`1`) or descending order (`0`).

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

See Also

- Order Structure in the *AWS Glue Developer Guide*

AWS Glue Table SerdeInfo

The `SerdeInfo` property type specifies information about a serialization/deserialization program (SerDe), which serves as an extractor and loader for an AWS Glue table.

`SerdeInfo` is a property of the StorageDescriptor (p. 1627) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Parameters" : JSON object,
  "SerializationLibrary" : String,
  "Name" : String
}
```

YAML

```
Parameters: JSON object
SerializationLibrary: String
Name: String
```

Properties

For more information, see SerDeInfo Structure in the *AWS Glue Developer Guide*.

`Parameters`

UTF-8 string–to–UTF-8 string key-value pairs that specify the initialization parameters for the SerDe.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`SerializationLibrary`

The serialization library. This is usually the class that implements the SerDe, such as `org.apache.hadoop.hive.serde2.columnar.ColumnarSerDe`. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the SerDe. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- SerDeInfo Structure in the *AWS Glue Developer Guide*

AWS Glue Table SkewedInfo

The `SkewedInfo` property type specifies skewed values (values that occur with very high frequency) in an AWS Glue table.

`SkewedInfo` is a property of the StorageDescriptor (p. 1627) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SkewedColumnNames" : [ String, ... ],
  "SkewedColumnValues" : [ String, ... ],
  "SkewedColumnValueLocationMaps" : JSON object
}
```

YAML

```
SkewedColumnNames:
  - String
SkewedColumnValues:
  - String
SkewedColumnValueLocationMaps: JSON object
```

Properties

For more information, see SkewedInfo Structure in the *AWS Glue Developer Guide*.

`SkewedColumnNames`

A list of UTF-8 strings that specify the names of columns that contain skewed values.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SkewedColumnValues`

A list of UTF-8 strings that specify values that appear so frequently that they're considered to be skewed.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SkewedColumnValueLocationMaps`

UTF-8 string–to–UTF-8 string key-value pairs that map skewed values to the columns that contain them.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

- SkewedInfo Structure in the *AWS Glue Developer Guide*

AWS Glue Table StorageDescriptor

The `StorageDescriptor` property type describes the physical storage of AWS Glue table data.

`StorageDescriptor` is a property of the TableInput (p. 1630) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "StoredAsSubDirectories" : Boolean,
  "Parameters" : JSON object,
  "BucketColumns" : [ String, ... ],
  "SkewedInfo" : SkewedInfo (p. 1626),
  "InputFormat" : String,
  "NumberOfBuckets" : Integer,
  "OutputFormat" : String,
  "Columns" : [ Column (p. 1623), ... ],
  "SerdeInfo" : SerdeInfo (p. 1625),
  "SortColumns" : [ Order (p. 1624), ... ],
  "Compressed" : Boolean,
  "Location" : String
}
```

YAML

```
StoredAsSubDirectories: Boolean
Parameters: JSON object
BucketColumns:
  - String
SkewedInfo:
  SkewedInfo (p. 1626)
InputFormat: String
NumberOfBuckets: Integer
OutputFormat: String
Columns:
  - Column (p. 1623)
```

```
SerdeInfo:
  SerdeInfo (p. 1625)
SortColumns:
  - Order (p. 1624)
Compressed: Boolean
Location: String
```

Properties

For more information, see StorageDescriptor Structure in the *AWS Glue Developer Guide*.

`StoredAsSubDirectories`

Indicates whether the table data is stored in subdirectories.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Parameters`

UTF-8 string–to–UTF-8 string key-value pairs that specify user-supplied properties.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`BucketColumns`

A list of UTF-8 strings that specify reducer grouping columns, clustering columns, and bucketing columns in the table.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SkewedInfo`

Information about values that appear very frequently in a column (skewed values).

Required: No

Type: SkewedInfo (p. 1626)

Update requires: No interruption (p. 120)

`InputFormat`

The input format: `SequenceFileInputFormat` (binary), `TextInputFormat`, or a custom format. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`NumberOfBuckets`

The number of buckets.

Required: Conditional. You must specify this property if the table contains any dimension columns.

Type: Integer

Update requires: No interruption (p. 120)

`OutputFormat`

The output format: `SequenceFileOutputFormat` (binary), `IgnoreKeyTextOutputFormat`, or a custom format. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Columns`

The columns in the table.

Required: No

Type: List of Column (p. 1623)

Update requires: No interruption (p. 120)

`SerdeInfo`

Information about a serialization/deserialization program (SerDe), which serves as an extractor and loader.

Required: No

Type: SerdeInfo (p. 1625)

Update requires: No interruption (p. 120)

`SortColumns`

The sort order of each bucket in the table.

Required: No

Type: List of Order (p. 1624)

Update requires: No interruption (p. 120)

`Compressed`

Indicates whether the data in the table is compressed.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Location`

The physical location of the table. By default, this takes the form of the warehouse location, followed by the database location in the warehouse, followed by the table name. It must match the URI address multi-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- StorageDescriptor Structure in the *AWS Glue Developer Guide*

AWS Glue Table TableInput

The `TableInput` property type specifies the metadata that's used to create or update an AWS Glue table.

`TableInput` is a property of the AWS::Glue::Table (p. 1621) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Owner" : String,
  "ViewOriginalText" : String,
  "Description" : String,
  "TableType" : String,
  "Parameters" : JSON object,
  "ViewExpandedText" : String,
  "StorageDescriptor" : StorageDescriptor (p. 1627),
  "PartitionKeys" : [ Column (p. 1623), ... ],
  "Retention" : Integer,
  "Name" : String
}
```

YAML

```
Owner: String
ViewOriginalText: String
Description: String
TableType: String
Parameters: JSON object
ViewExpandedText: String
StorageDescriptor:
  StorageDescriptor (p. 1627)
PartitionKeys:
  - Column (p. 1623)
Retention: Integer
Name: String
```

Properties

For more information, see TableInput Structure in the *AWS Glue Developer Guide*.

`Owner`

The owner of the table. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`ViewOriginalText`

The original text of the view, if the table is a view. Otherwise, it's `null`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the table. It must match the URI address multi-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\r\n\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`TableType`

The type of the table, such as `EXTERNAL_TABLE` or `VIRTUAL_VIEW`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Parameters`

UTF-8 string–to–UTF-8 string key-value pairs that specify the properties that are associated with the table.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`ViewExpandedText`

The expanded text of the view, if the table is a view. Otherwise it's `null`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`StorageDescriptor`

Information about the physical storage of the table.

Required: No

Type: StorageDescriptor (p. 1627)

Update requires: No interruption (p. 120)

`PartitionKeys`

The columns in the table.

Required: No

Type: List of Column (p. 1623)

Update requires: No interruption (p. 120)

`Retention`

The retention time for the table.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Name`

The name of the table. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: Yes

Type: String

Update requires: Replacement (p. 121)

AWS::Glue::Trigger

The `AWS::Glue::Trigger` resource specifies triggers that run AWS Glue jobs. For more information, see Triggering Jobs in AWS Glue and Trigger Structure in the *AWS Glue Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Glue::Trigger",
  "Properties" : {
    "Type" : String,
    "Description" : String,
    "Actions" : [ Action (p. 1638), ... ],
    "Schedule" : String,
    "Name" : String,
    "Predicate" : Predicate (p. 1639)
  }
}
```

YAML

```
Type: AWS::Glue::Trigger
Properties:
  Type: String
  Description: String
  Actions:
```

```
    - Action (p. 1638)
  Schedule: String
  Name: String
  Predicate:
    Predicate (p. 1639)
```

Properties

`Type`

The type of job trigger. Valid values are `SCHEDULED`, `CONDITIONAL`, or `ON_DEMAND`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the job trigger.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Actions`

The actions that the job trigger initiates when it fires.

Required: Yes

Type: List of Action (p. 1638)

Update requires: No interruption (p. 120)

`Schedule`

The `cron` schedule expression for the job trigger.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the job trigger.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Predicate`

The predicate of the job trigger, which determines when the trigger fires.

Required: No

Type: Predicate (p. 1639)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

On-Demand Trigger

The following example creates an on-demand trigger that triggers one job.

JSON

```
{
  "Resources": {
    "OnDemandJobTrigger": {
      "Type": "AWS::Glue::Trigger",
      "Properties": {
        "Type": "ON_DEMAND",
        "Description": "DESCRIPTION_ON_DEMAND",
        "Actions": [
          {
            "JobName": "prod-job2"
          }
        ],
        "Name": "prod-trigger1-ondemand"
      }
    }
  }
}
```

YAML

```
Resources:
  OnDemandJobTrigger:
    Type: AWS::Glue::Trigger
    Properties:
      Type: ON_DEMAND
      Description: DESCRIPTION_ON_DEMAND
      Actions:
        - JobName: prod-job2
      Name: prod-trigger1-ondemand
```

Scheduled Trigger

The following example creates a scheduled trigger that runs every two hours and triggers two jobs. Note that it declares an argument for `prod-job3`.

JSON

```
{
  "Resources": {
    "ScheduledJobTrigger": {
```

```
      "Type": "AWS::Glue::Trigger",
      "Properties": {
        "Type": "SCHEDULED",
        "Description": "DESCRIPTION_SCHEDULED",
        "Schedule": "cron(0 */2 * * ? *)",
        "Actions": [
          {
            "JobName": "prod-job2"
          },
          {
            "JobName": "prod-job3",
            "Arguments": {
              "--job-bookmark-option": "job-bookmark-enable"
            }
          }
        ],
        "Name": "prod-trigger1-scheduled"
      }
    }
  }
}
```

YAML

```
Resources:
  ScheduledJobTrigger:
    Type: AWS::Glue::Trigger
    Properties:
      Type: SCHEDULED
      Description: DESCRIPTION_SCHEDULED
      Schedule: cron(0 */2 * * ? *)
      Actions:
        - JobName: prod-job2
        - JobName: prod-job3
          Arguments:
            '--job-bookmark-option': job-bookmark-enable
      Name: prod-trigger1-scheduled
```

Conditional Trigger

The following example creates a conditional trigger that starts a job based on the successful completion of the job run.

JSON

```
{
  "Description": "AWS Glue Trigger Test",
  "Resources": {
    "MyJobTriggerRole": {
      "Type": "AWS::IAM::Role",
      "Properties": {
        "AssumeRolePolicyDocument": {
          "Version": "2012-10-17",
          "Statement": [
            {
              "Effect": "Allow",
              "Principal": {
                "Service": [
                  "glue.amazonaws.com"
                ]
              },
              "Action": [
                "sts:AssumeRole"
```

```
              ]
            }
          ]
        },
        "Path": "/",
        "Policies": [
          {
            "PolicyName": "root",
            "PolicyDocument": {
              "Version": "2012-10-17",
              "Statement": [
                {
                  "Effect": "Allow",
                  "Action": "*",
                  "Resource": "*"
                }
              ]
            }
          }
        ]
      }
    },
    "MyJob": {
      "Type": "AWS::Glue::Job",
      "Properties": {
        "Name": "MyJobTriggerJob",
        "LogUri": "wikiData",
        "Role": {
          "Ref": "MyJobTriggerRole"
        },
        "Command": {
          "Name": "glueetl",
          "ScriptLocation": "s3://testdata-bucket/s3-target/create-delete-job-xtf-ETL-s3-
json-to-csv.py"
        },
        "DefaultArguments": {
          "--job-bookmark-option": "job-bookmark-enable"
        },
        "MaxRetries": 0
      }
    },
    "MyJobTrigger": {
      "Type": "AWS::Glue::Trigger",
      "Properties": {
        "Name": "MyJobTrigger",
        "Type": "CONDITIONAL",
        "Description": "Description for a conditional job trigger",
        "Actions": [
          {
            "JobName": {
              "Ref": "MyJob"
            },
            "Arguments": {
              "--job-bookmark-option": "job-bookmark-enable"
            }
          }
        ],
        "Predicate": {
          "Conditions": [
            {
              "LogicalOperator": "EQUALS",
              "JobName": {
                "Ref": "MyJob"
              },
              "State": "SUCCEEDED"
            }
```

```
          ]
        }
      }
    }
  }
}
```

YAML

```
---

```

AWS Glue Trigger Action

The `Action` property type specifies the actions that an AWS Glue job trigger initiates when it fires.

`Action` is a property of the AWS::Glue::Trigger (p. 1632) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "JobName" : String,
  "Arguments" : JSON object
}
```

YAML

```
JobName: String
Arguments: JSON object
```

Properties

`JobName`

The name of the associated job. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Arguments`

UTF-8 string–to–UTF-8 string key-value pairs that specify the arguments for the action.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

See Also

- Action Structure in the *AWS Glue Developer Guide*

AWS Glue Trigger Condition

The `Condition` property type specifies a condition for an AWS Glue job trigger predicate.

The `Conditions` property of the Predicate (p. 1639) property type contains a list of `Condition` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "LogicalOperator" : String,
  "JobName" : String,
  "State" : String
}
```

YAML

```
LogicalOperator: String
JobName: String
State: String
```

Properties

`LogicalOperator`

The logical operator for the condition.

Valid values: `EQUALS`

Required: No

Type: String

Update requires: No interruption (p. 120)

`JobName`

The name of the associated job. It must match the single-line string pattern: `[\u0020-\uD7FF\uE000-\uFFFD\uD800\uDC00-\uDBFF\uDFFF\t]*`

Required: No

Type: String

Update requires: No interruption (p. 120)

`State`

The state of the condition.

Valid values: `SUCCEEDED`

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- Condition Structure in the *AWS Glue Developer Guide*

AWS Glue Trigger Predicate

The `Predicate` property type specifies the predicate of an AWS Glue job trigger, which determines when it fires.

`Predicate` is a property of the AWS::Glue::Trigger (p. 1632) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Logical" : String,
  "Conditions" : [ Condition (p. 1638), ... ]
}
```

YAML

```
Logical: String
Conditions:
  - Condition (p. 1638)
```

Properties

`Logical`

The logical operator for the predicate.

Valid values: `AND`

Required: Optional field if only one condition is listed. If multiple conditions are listed, then this field is required.

Type: String

Update requires: No interruption (p. 120)

`Conditions`

The conditions that determine when the trigger fires.

Required: No

Type: List of Condition (p. 1638)

Update requires: No interruption (p. 120)

See Also

- Predicate Structure in the *AWS Glue Developer Guide*

Amazon GuardDuty Resource Types Reference

This section contains reference information for all Amazon GuardDuty resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::GuardDuty::data-type-name
```

Topics

- AWS::GuardDuty::Detector (p. 1641)
- AWS::GuardDuty::Filter (p. 1642)
- AWS::GuardDuty::Master (p. 1647)
- AWS::GuardDuty::Member (p. 1649)
- AWS::GuardDuty::IPSet (p. 1652)
- AWS::GuardDuty::ThreatIntelSet (p. 1654)

AWS::GuardDuty::Detector

The `AWS::GuardDuty::Detector` resource creates a single Amazon GuardDuty detector. A detector is an object that represents the GuardDuty service. You must create a detector for GuardDuty to become operational.

Topics

- Syntax (p. 1641)
- Properties (p. 1641)
- Return Values (p. 1642)
- Examples (p. 1642)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::GuardDuty::Detector",
  "Properties" : {
    "Enable" : Boolean,
    "FindingPublishingFrequency : String
  }
}
```

YAML

```
Type: AWS::GuardDuty::Detector
Properties:
  Enable: Boolean
  FindingPublishingFrequency: String
```

Properties

`Enable`

A Boolean value that specifies whether the detector is to be enabled.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

`FindingPublishingFrequency`

Specifies the frequency of notifications sent about the subsequent finding occurrences. Valid values include only the following: FIFTEEN_MINUTES, ONE_HOUR, SIX_HOURS.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::GuardDuty::Detector` resource to the intrinsic `Ref` function, the function returns the unique ID of the created detector.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Declaring a GuardDuty Detector Resource

The following example shows how to declare an `AWS::GuardDuty::Detector` resource to create a GuardDuty detector.

JSON

```
"mydetector": {
  "Type": "AWS::GuardDuty::Detector",
  "Properties": {
    "Enable": true,
    "FindingPublishingFrequency": "FIFTEEN_MINUTES"
  }
}
```

YAML

```
mydetector:
  Type: AWS::GuardDuty::Detector
  Properties:
    Enable: true
    FindingPublishingFrequency: FIFTEEN_MINUTES
```

AWS::GuardDuty::Filter

You can use the `AWS::GuardDuty::Filter` resource to create a GuardDuty filter using the specified finding criteria.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::GuardDuty::Filter",
  "Properties" : {
    "Action" : String,
    "Description" : String,
    "DetectorId" : String,
    "FindingCriteria" : FindingCriteria (p. 1646),
    "Rank" : Integer,
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::GuardDuty::Filter"
Properties:
  Action: String
  Description: String
  DetectorId: String
  FindingCriteria: FindingCriteria (p. 1646)
  Rank: Integer
  Name: String
```

Properties

`Action`

Specifies the action that is to be applied to the findings that match the filter. Valid values are: NOOP | ARCHIVE

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the filter.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`DetectorId`

The ID of the detector that specifies the GuardDuty service whose findings you want to filter.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`FindingCriteria`

Represents the criteria to be used in the filter for querying findings.

Required: Yes

Type: FindingCriteria (p. 1646)

Update requires: No interruption (p. 120)

`Rank`

Specifies the position of the filter in the list of current filters. Also specifies the order in which this filter is applied to the findings.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

`Name`

The name of the filter.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::GuardDuty::Filter` resource to the intrinsic `Ref` function, the function returns the name of the created filter, such as `SampleFilter`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Declaring a GuardDuty Member Resource

The following example shows how to declare an AWS::GuardDuty::Filter resource to create a filter for your GuardDuty findings.

JSON

```
{
  "Type": "AWS::GuardDuty::Filter",
  "Properties": {
    "Action": "ARCHIVE",
    "Description": "SampleFilter",
    "DetectorId": "a12abc34d567e8fa901bc2d34e56789f0",
    "FindingCriteria": {
      "Criterion": {
        "updatedAt": {
          "Gte": 0
        }
      }
    },
    "Rank": 1,
    "Name": "SampleFilter"
```

```
  }
}
```

YAML

```
Type: "AWS::GuardDuty::Filter"
Properties:
 Action : "ARCHIVE"
 Description : "SampleFilter"
 DetectorId : "a12abc34d567e8fa901bc2d34e56789f0"
 FindingCriteria :
   Criterion:
      "updatedAt":
          Gte: 0
 Rank : 1
 Name : "SampleFilter"
```

Amazon GuardDuty Filter Condition

The `Condition` property type specifies the condition to be applied to a single field when filtering through GuardDuty findings.

`Condition` is a property of the FindingCriteria (p. 1646) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Lt" : Integer,
  "Gte" : Integer,
  "Neq" : [ String, ... ],
  "Eq" : [ String, ... ],
  "Lte" : Integer
}
```

YAML

```
Lt: Integer
Gte: Integer
Neq:
  - String
Eq:
  - String
Lte: Integer
```

Properties

`Lt`

Represents the "less than" condition to be applied to a single field when filtering through findings.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Gte`

Represents the "greater than equal" condition to be applied to a single field when filtering through findings.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Neq`

Represents the "not equal to" condition to be applied to a single field when filtering through findings.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Eq`

Represents the "equal to" condition to be applied to a single field when filtering through findings.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Lte`

Represents the "less than equal" condition to be applied to a single field when filtering through findings.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

Amazon GuardDuty Filter FindingCriteria

The `FindingCriteria` property type specifies the attributes to be used in the filter and the conditions to be applied to the selected attributes for filtering through your GuardDuty findings.

`FindingCriteria` is a property of the AWS::GuardDuty::Filter (p. 1642) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Criterion" : Json,
  "ItemType" : Condition (p. 1645)
}
```

YAML

```
Criterion: Json
ItemType: Condition (p. 1645)
```

Properties

`Criterion`

Specifies the finding attributes (for example, region, type, severity, etc.) that you want to include in the finding criteria for a filter.

Required: No

Type: Json

Update requires: No interruption (p. 120)

`ItemType`

Specifies the condition to be applied to a single field when filtering through findings.

Required: No

Type: Condition (p. 1645)

Update requires: No interruption (p. 120)

AWS::GuardDuty::Master

You can use the `AWS::GuardDuty::Master` resource in a GuardDuty member account to accept an invitation to be managed by a GuardDuty master account. The GuardDuty master account must have already invited the current account (by calling the InviteMembers API operation or by creating an `AWS::GuardDuty::Member` resource) before the current account can use the `AWS::GuardDuty::Master` resource to accept the master account's invitation.

Topics

- Syntax (p. 1647)
- Properties (p. 1648)
- Return Values (p. 1649)
- Examples (p. 1649)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::GuardDuty::Master",
```

```
  "Properties" : {
    "DetectorId" : String,
    "MasterId" : String,
    "InvitationId" : String
  }
}
```

YAML

```
Type: AWS::GuardDuty::Master
Properties:
  DetectorId: String
  MasterId: String
  InvitationId: String
```

Properties

`DetectorId`

The detector ID of the AWS account that is accepting an invitation to become a GuardDuty member account.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`MasterId`

The account ID of the master GuardDuty account whose invitation you're accepting.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`InvitationId`

The ID of the invitation that is sent to the AWS account by the GuardDuty master account. There are several ways to retrieve the invitationId:

- By calling the ListInvitation API operation with the GuardDuty member account's credentials. (You can also run the following CLI command: `aws guardduty list-invitations`.) In the returned results, locate the invitation details (including the invitationID) from the GuardDuty master account ID that you would like to accept.
- The email account associated with the GuardDuty member account should have received an invitation email from the master account when they invited the current account. This email contains an acceptance link which has the invitationId.
- If you access the member account's Personal Health Dashboard, you can also see the same invitation email from the master account (with the invitationId included as part of the invitation acceptance link).
- If the value for InvitationId is not specified, it can be retrieved by calling ListInvitations and receiving the invitation from the given master account ID.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::GuardDuty::Master` resource to the intrinsic `Ref` function, the function returns the unique ID of the GuardDuty master account, such as `012345678901`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Declaring a GuardDuty Master Resource

The following example shows how to declare an `AWS::GuardDuty::Master` resource to create a GuardDuty master account.

JSON

```
"GDmaster": {
  "Type": "AWS::GuardDuty::Master",
  "Properties": {
    "DetectorId": "a12abc34d567e8fa901bc2d34e56789f0",
    "MasterId": "012345678901",
    "InvitationId": "84b097800250d17d1872b34c4daadcf5"
   }
}
```

YAML

```
GDmaster:
  Type: AWS::GuardDuty::Master
  Properties:
    DetectorId: "a12abc34d567e8fa901bc2d34e56789f0"
    MasterId: "012345678901"
    InvitationId: "84b097800250d17d1872b34c4daadcf5"
```

AWS::GuardDuty::Member

You can use the `AWS::GuardDuty::Member` resource to add an AWS account as a GuardDuty member account to the current GuardDuty master account. If the value of the `Status` property is not provided or is set to `Created`, a member account is only created. If the value of the `Status` property is set to `Invited`, a member account is created and invited. `AWS::GuardDuty::Member` resource has to be created with the `Status` property set to `Invited` before the `AWS::GuardDuty::Master` resource can be created in a GuardDuty member account.

Topics

- Syntax (p. 1650)
- Properties (p. 1650)
- Return Values (p. 1651)
- Examples (p. 1651)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::GuardDuty::Member",
  "Properties" : {
    "Status" : String,
    "MemberId" : String,
    "Email" : String,
    "Message" : String,
    "DetectorId" : String,
    "DisableEmailNotification" : Boolean
  }
}
```

YAML

```
Type: AWS::GuardDuty::Member
Properties:
  Status: String
  MemberId: String
  Email: String
  Message: String
  DetectorId: String
  DisableEmailNotification: Boolean
```

Properties

`Status`

You can use this property to update the status of the relationship between the member account and its master account. Valid values are Created | Invited | Disabled | Enabled | Removed | Resigned. If the value for this property is not provided or set to Created, a member account is only created. If the value of this property is set to Invited, a member account is created and invited.

Required: No

Type: String

Update requires: No interruption (p. 120)

`MemberId`

The account ID of the member GuardDuty account.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Email`

The email address of the GuardDuty member account.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Message`

The invitation message that you want to send to the account that you invite to GuardDuty as a member.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DetectorId`

The unique ID of the detector in a GuardDuty master account.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`DisableEmailNotification`

Specifies whether an email notification is sent to the accounts that you want to invite to GuardDuty as members. When set to 'True', email notification is not sent to the invitees.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::GuardDuty::Member` resource to the intrinsic `Ref` function, the function returns the unique ID of the GuardDuty member account, such as `012345678901`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Declaring a GuardDuty Member Resource

The following example shows how to declare an AWS::GuardDuty::Member resource to create a GuardDuty member account.

JSON

```
"GDmaster": {
  "Type": "AWS::GuardDuty::Member",
  "Properties": {
    "Status": "Invited",
    "MemberId": "012345678901",
    "Email": "guarddutymember@amazon.com",
    "Message": "You are invited to enable Amazon Guardduty.",
    "DetectorId": "a12abc34d567e8fa901bc2d34e56789f0",
```

```
    "DisableEmailNotification": true
    }
}
```

YAML

```
GDmaster:
  Type: AWS::GuardDuty::Member
  Properties:
    Status: "Invited"
    MemberId: "012345678901"
    Email: "guarddutymember@amazon.com"
    Message: "You are invited to enable Amazon Guardduty."
    DetectorId: "a12abc34d567e8fa901bc2d34e56789f0"
    DisableEmailNotification: true
```

AWS::GuardDuty::IPSet

The `AWS::GuardDuty::IPSet` resource creates an Amazon GuardDuty IP set. An IP set is a list of trusted IP addresses that have been whitelisted for secure communication with your AWS environment.

Topics

- Syntax (p. 1652)
- Properties (p. 1653)
- Return Values (p. 1653)
- Examples (p. 1654)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::GuardDuty::IPSet",
  "Properties" : {
    "Activate" : Boolean,
    "DetectorId" : String,
    "Format" : String,
    "Location" : String,
    "Name" : String
  }
}
```

YAML

```
Type: AWS::GuardDuty::IPSet
Properties:
  Activate: Boolean
  DetectorId: String
  Format: String
  Location: String
  Name: String
```

Properties

`Activate`

A Boolean value that indicates whether GuardDuty is to start using the uploaded IP set.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

`DetectorId`

The detector ID that specifies the GuardDuty service for which an IP set is to be created.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Format`

The format of the file that contains the IP set. Valid values are TXT, STIX, and OTX_CSV.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Location`

The URI of the file that contains the IP set.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Name`

The friendly name to identify the IP set. This name is displayed in all findings that are triggered by activity that involves IP addresses included in this IP set.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::GuardDuty::IPSet` resource to the intrinsic `Ref` function, the function returns the unique ID of the created IP set.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Declaring a GuardDuty IPSet Resource

The following example shows how to declare an AWS::GuardDuty::IPSet resource to create a GuardDuty IP set.

JSON

```
"myipset”: {
  "Type": "AWS::GuardDuty::IPSet",
  "Properties": {
    "Activate": true,
    "DetectorId": "12abc34d567e8f4912ab3d45e67891f2",
    "Format": "TXT",
    "Location": "https://s3-us-west-2.amazonaws.com/mybucket/myipset.txt",
    "Name": "MyIPSet"
  }
}
```

YAML

```
myipset:
  Type: AWS::GuardDuty::IPSet
  Properties:
    Activate: true
    DetectorId: "12abc34d567e8f4912ab3d45e67891f2"
    Format: "TXT"
    Location: "https://s3-us-west-2.amazonaws.com/mybucket/myipset.txt"
    Name: "MyIPSet"
```

AWS::GuardDuty::ThreatIntelSet

The `AWS::GuardDuty::ThreatIntelSet` resource creates a ThreatIntelSet. A ThreatIntelSet consists of known malicious IP addresses. GuardDuty generates findings based on ThreatIntelSets.

Topics

- Syntax (p. 1654)
- Properties (p. 1655)
- Return Values (p. 1656)
- Examples (p. 1656)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::GuardDuty::ThreatIntelSet",
  "Properties" : {
    "Activate" : Boolean,
    "DetectorId" : String,
    "Format" : String,
    "Location" : String,
    "Name" : String
  }
```

```
}
```

YAML

```
Type: AWS::GuardDuty::ThreatIntelSet
Properties:
  Activate: Boolean
  DetectorId: String
  Format: String
  Location: String
  Name: String
```

Properties

`Activate`

A Boolean value that indicates whether GuardDuty should start using the uploaded ThreatIntelSet.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

`DetectorId`

The detector ID that specifies the GuardDuty service for which an ThreatIntelSet is to be created.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Format`

The format of the file that contains the ThreatIntelSet. Valid values are TXT, STIX, OTX_CSV, ALIEN_VAULT, PROOF_POINT, and FIRE_EYE.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Location`

The URI of the file that contains the ThreatIntelSet.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Name`

A friendly ThreatIntelSet name that is displayed in all findings generated by activity that involves IP addresses included in this ThreatIntelSet.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::GuardDuty::ThreatIntelSet` resource to the intrinsic `Ref` function, the function returns the unique ID of the created threatIntelSet.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Declaring a GuardDuty ThreatIntelSet resource

The following example shows how to declare an AWS::GuardDuty::ThreatIntelSet resource to create a GuardDuty ThreatIntelSet.

JSON

```
"mythreatintelset": {
  "Type": "AWS::GuardDuty::ThreatIntelSet",
  "Properties": {
    "Activate": true,
    "DetectorId": "12abc34d567e8f4912ab3d45e67891f2",
    "Format": "TXT",
    "Location": "https://s3-us-west-2.amazonaws.com/mybucket/mythreatintelset.txt",
    "Name": "MyThreatIntelSet"
  }
}
```

YAML

```
mythreatintelset:
  Type: AWS::GuardDuty::ThreatIntelSet
  Properties:
    Activate: true
    DetectorId: "12abc34d567e8f4912ab3d45e67891f2"
    Format: "TXT"
    Location: "https://s3-us-west-2.amazonaws.com/mybucket/mythreatintelset.txt"
    Name: "MyThreatIntelSet"
```

AWS Identity and Access Management Resource Types Reference

This section contains reference information for all AWS Identity and Access Management resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::IAM::data-type-name
```

Topics

- AWS::IAM::AccessKey (p. 1657)
- AWS::IAM::Group (p. 1658)

- AWS::IAM::InstanceProfile (p. 1660)
- AWS::IAM::ManagedPolicy (p. 1662)
- AWS::IAM::Policy (p. 1666)
- AWS::IAM::Role (p. 1670)
- AWS::IAM::ServiceLinkedRole (p. 1676)
- AWS::IAM::User (p. 1678)
- AWS::IAM::UserToGroupAddition (p. 1681)

AWS::IAM::AccessKey

The AWS::IAM::AccessKey resource type generates a secret access key and assigns it to an IAM user or AWS account.

This type supports updates. For more information about updating stacks, see AWS CloudFormation Stacks Updates (p. 120).

Topics

- Syntax (p. 1657)
- Properties (p. 1657)
- Return Values (p. 1658)
- Template Examples (p. 1658)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type": "AWS::IAM::AccessKey",
   "Properties": {
      "Serial (p. 1657)": Integer,
      "Status (p. 1658)": String,
      "UserName (p. 1658)": String
   }
}
```

YAML

```
Type: AWS::IAM::AccessKey
Properties:
  Serial (p. 1657): Integer
  Status (p. 1658): String
  UserName (p. 1658): String
```

Properties

`Serial`

This value is specific to AWS CloudFormation and can only be *incremented*. Incrementing this value notifies AWS CloudFormation that you want to rotate your access key. When you update your stack, AWS CloudFormation will replace the existing access key with a new key.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`Status`

The status of the access key. By default, AWS CloudFormation sets this property value to `Active`.

Required: No

Type: String

Valid values: `Active` or `Inactive`

Update requires: No interruption (p. 120)

`UserName`

The name of the user that the new key will belong to.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

Specifying this resource ID to the intrinsic `Ref` function will return the `AccessKeyId`. For example: `AKIAIOSFODNN7EXAMPLE`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`SecretAccessKey`

Returns the secret access key for the specified `AWS::IAM::AccessKey` resource. For example: `wJalrXUtnFEMI/K7MDENG/bPxRfiCYzEXAMPLEKEY`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Template Examples

To view AWS::IAM::AccessKey snippets, see Declaring an IAM Access Key Resource (p. 396).

AWS::IAM::Group

The `AWS::IAM::Group` resource creates an AWS Identity and Access Management (IAM) group.

This type supports updates. For more information about updating stacks, see AWS CloudFormation Stacks Updates (p. 120).

Topics

- Syntax (p. 1659)
- Properties (p. 1659)
- Return Values (p. 1660)
- Template Examples (p. 1660)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type": "AWS::IAM::Group",
   "Properties": {
      "GroupName": String,
      "ManagedPolicyArns": [ String, ... ],
      "Path": String,
      "Policies": [ Policies, ... ]
   }
}
```

YAML

```
Type: AWS::IAM::Group
Properties:
  GroupName: String
  ManagedPolicyArns: [ String, ... ]
  Path: String
  Policies:
    - Policies
```

Properties

`GroupName`

A name for the IAM group. For valid values, see the `GroupName` parameter for the `CreateGroup` action in the *IAM API Reference*. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the group name.

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

If you specify a name, you must specify the `CAPABILITY_NAMED_IAM` value to acknowledge your template's capabilities. For more information, see Acknowledging IAM Resources in AWS CloudFormation Templates (p. 15).

> **Warning**
> Naming an IAM resource can cause an unrecoverable error if you reuse the same template in multiple regions. To prevent this, we recommend using `Fn::Join` and `AWS::Region` to create a region-specific name, as in the following example: `{"Fn::Join": ["", [{"Ref": "AWS::Region"}, {"Ref": "MyResourceName"}]]}`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ManagedPolicyArns`

One or more managed policy ARNs to attach to this group.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Path`

The path to the group. For more information about paths, see IAM Identifiers in the *IAM User Guide*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Policies`

The policies to associate with this group. For information about policies, see Overview of IAM Policies in the *IAM User Guide*.

Required: No

Type: List of IAM Policies (p. 1669)

Update requires: No interruption (p. 120)

Return Values

Ref

Specifying this resource ID to the intrinsic `Ref` function will return the `GroupName`. For example: `mystack-mygroup-1DZETITOWEKVO`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

Returns the Amazon Resource Name (ARN) for the `AWS::IAM::Group` resource. For example: `arn:aws:iam::123456789012:group/mystack-mygroup-1DZETITOWEKVO`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Template Examples

To view AWS::IAM::Group snippets, see Declaring an IAM Group Resource (p. 397)

AWS::IAM::InstanceProfile

The `AWS::IAM::InstanceProfile` resource creates an AWS Identity and Access Management (IAM) instance profile that can be used with IAM roles for EC2 instances.

For more information about IAM roles, see Working with Roles in the *AWS Identity and Access Management User Guide*.

Topics

- Syntax (p. 1661)
- Properties (p. 1661)
- Return Values (p. 1662)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type": "AWS::IAM::InstanceProfile",
   "Properties": {
      "Path (p. 1661)": String,
      "Roles (p. 1661)": [ IAM Roles ],
      "InstanceProfileName (p. 1662)": String
   }
}
```

YAML

```
Type: AWS::IAM::InstanceProfile
Properties:
  Path (p. 1661): String
  Roles (p. 1661):
    - IAM Roles
  InstanceProfileName (p. 1662): String
```

Properties

`Path`

The path associated with this IAM instance profile. For information about IAM paths, see Friendly Names and Paths in the *AWS Identity and Access Management User Guide*.

By default, AWS CloudFormation specifies `/` for the path.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Roles`

The name of an existing IAM role to associate with this instance profile. Currently, you can assign a maximum of one role to an instance profile.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`InstanceProfileName`

The name of the instance profile that you want to create. This parameter allows (per its regex pattern) a string consisting of upper and lowercase alphanumeric characters with no spaces. You can also include any of the following characters: `= , . @ -`.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyProfile" }
```

For the `IAM::InstanceProfile` with the logical ID `MyProfile`, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

Returns the Amazon Resource Name (ARN) for the instance profile. For example:

```
{"Fn::GetAtt" : ["MyProfile", "Arn"] }
```

This returns a value such as `“arn:aws:iam::1234567890:instance-profile/MyProfile-ASDNSDLKJ”`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

AWS::IAM::ManagedPolicy

`AWS::IAM::ManagedPolicy` creates an AWS Identity and Access Management (IAM) managed policy for your AWS account, which you can use to apply permissions to IAM users, groups, and roles. For more information about managed policies, see Managed Policies and Inline Policies in the *IAM User Guide* guide.

Topics

- Syntax (p. 1663)
- Properties (p. 1663)
- Return Values (p. 1665)
- Example (p. 1665)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type": "AWS::IAM::ManagedPolicy",
  "Properties": {
    "Description" : String,
    "Groups" : [ String, ... ],
    "Path" : String,
    "PolicyDocument" : JSON object,
    "Roles" : [ String, ... ],
    "Users" : [ String, ... ],
    "ManagedPolicyName" : String
  }
}
```

YAML

```
Type: AWS::IAM::ManagedPolicy
Properties:
  Description: String
  Groups:
    - String
  Path: String
  PolicyDocument: JSON object
  Roles:
    - String
  Users:
    - String
  ManagedPolicyName: String
```

Properties

`Description`

A description of the IAM policy. For example, describe the permissions that are defined in the policy.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Groups`

The names of IAM groups to attach to this policy.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Path`

The path for the IAM policy. By default, the path is `/`. For more information, see IAM Identifiers in the *IAM User Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PolicyDocument`

Policies that define the permissions for this managed policy. For more information about policy syntax, see IAM Policy Elements Reference in *IAM User Guide*.

Required: Yes

Type: JSON object

> **Note**
> AWS Identity and Access Management (IAM) requires that policies be in JSON format. However, for templates formatted in YAML, you can create an IAM policy in either JSON or YAML format. AWS CloudFormation always converts a policy to JSON format before submitting it to IAM.

Update requires: No interruption (p. 120)

`Roles`

The names of IAM roles to attach to this policy.

> **Note**
> If a policy has a `Ref` to a role and if a resource (such as `AWS::ECS::Service`) also has a `Ref` to the same role, add a `DependsOn` attribute to the resource so that the resource depends on the policy. This dependency ensures that the role's policy is available throughout the resource's lifecycle. For example, when you delete a stack with an `AWS::ECS::Service` resource, the `DependsOn` attribute ensures that the `AWS::ECS::Service` resource can complete its deletion before its role's policy is deleted.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Users`

The names of users to attach to this policy.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`ManagedPolicyName`

A custom, friendly name for your IAM managed policy. For valid values, see the PolicyName parameter of the `CreatePolicy` action in the *IAM API Reference*.

If you don't specify a `PolicyName`, AWS CloudFormation generates a unique physical ID and uses that ID for the policy name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the ARN.

In the following sample, the `Ref` function returns the ARN of the `CreateTestDBPolicy` managed policy, such as `arn:aws:iam::123456789012:policy/teststack-CreateTestDBPolicy-16M23YE3CS700`.

```
{ "Ref": "CreateTestDBPolicy" }
```

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a managed policy and associates it with the `TestDBGroup` group. The managed policy grants users permission to create t2.micro database instances. The database must use the MySQL database engine and the instance name must include the prefix `test`.

JSON

```
"CreateTestDBPolicy" : {
  "Type" : "AWS::IAM::ManagedPolicy",
  "Properties" : {
    "Description" : "Policy for creating a test database",
    "Path" : "/",
    "PolicyDocument" :   {
      "Version":"2012-10-17",
      "Statement" : [{
        "Effect" : "Allow",
        "Action" : "rds:CreateDBInstance",
        "Resource" : {"Fn::Join" : [ "", [ "arn:aws:rds:", { "Ref" : "AWS::Region" }, ":",
 { "Ref" : "AWS::AccountId" }, ":db:test*" ] ]},
        "Condition" : {
          "StringEquals" : { "rds:DatabaseEngine" : "mysql" }
        }
      },
      {
        "Effect" : "Allow",
        "Action" : "rds:CreateDBInstance",
        "Resource" : {"Fn::Join" : [ "", [ "arn:aws:rds:", { "Ref" : "AWS::Region" }, ":",
 { "Ref" : "AWS::AccountId" }, ":db:test*" ] ]},
        "Condition" : {
          "StringEquals" : { "rds:DatabaseClass" : "db.t2.micro" }
        }
      }]
    },
    "Groups" : ["TestDBGroup"]
  }
}
```

YAML

```
CreateTestDBPolicy:
  Type: AWS::IAM::ManagedPolicy
  Properties:
    Description: "Policy for creating a test database"
```

```
    Path: "/"
    PolicyDocument:
      Version: "2012-10-17"
      Statement:
        -
          Effect: "Allow"
          Action: "rds:CreateDBInstance"
          Resource:
            Fn::Join:
              - ""
              -
                - "arn:aws:rds:"
                -
                  Ref: "AWS::Region"
                - ":"
                -
                  Ref: "AWS::AccountId"
                - ":db:test*"
          Condition:
            StringEquals:
              rds:DatabaseEngine: "mysql"
        -
          Effect: "Allow"
          Action: "rds:CreateDBInstance"
          Resource:
            Fn::Join:
              - ""
              -
                - "arn:aws:rds:"
                -
                  Ref: "AWS::Region"
                - ":"
                -
                  Ref: "AWS::AccountId"
                - ":db:test*"
          Condition:
            StringEquals:
              rds:DatabaseClass: "db.t2.micro"
    Groups:
      - "TestDBGroup"
```

AWS::IAM::Policy

The `AWS::IAM::Policy` resource associates an IAM policy with IAM users, roles, or groups. For more information about IAM policies, see Overview of IAM Policies in the *IAM User Guide* guide.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::IAM::Policy",
  "Properties" : {
    "Groups (p. 1667)" : [ String, ... ],
    "PolicyDocument (p. 1667)" : JSON object,
    "PolicyName (p. 1667)" : String,
    "Roles (p. 1667)" : [ String, ... ],
    "Users (p. 1668)" : [ String, ... ]
  }
}
```

YAML

```
Type: AWS::IAM::Policy
Properties:
  Groups (p. 1667):
    - String
  PolicyDocument (p. 1667): JSON object
  PolicyName (p. 1667): String
  Roles (p. 1667):
    - String
  Users (p. 1668):
    - String
```

Properties

`Groups`

The names of groups to which you want to add the policy.

Required: Conditional. You must specify at least one of the following properties: `Groups`, `Roles`, or `Users`.

Type: List of String values

Update requires: No interruption (p. 120)

`PolicyDocument`

A policy document that contains permissions to add to the specified users or groups.

Required: Yes

Type: JSON object

> **Note**
> AWS Identity and Access Management (IAM) requires that policies be in JSON format. However, for templates formatted in YAML, you can create an IAM policy in either JSON or YAML format. AWS CloudFormation always converts a policy to JSON format before submitting it to IAM.

Update requires: No interruption (p. 120)

`PolicyName`

The name of the policy. If you specify multiple policies for an entity, specify unique names. For example, if you specify a list of policies for an IAM role, each policy must have a unique name.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Roles`

The names of AWS::IAM::Role (p. 1670)s to which this policy will be attached.

> **Note**
> If a policy has a `Ref` to a role and if a resource (such as `AWS::ECS::Service`) also has a `Ref` to the same role, add a `DependsOn` attribute to the resource so that the resource depends on the policy. This dependency ensures that the role's policy is available throughout the resource's lifecycle. For example, when you delete a stack

with an `AWS::ECS::Service` resource, the `DependsOn` attribute ensures that the `AWS::ECS::Service` resource can complete its deletion before its role's policy is deleted.

Required: Conditional. You must specify at least one of the following properties: `Groups`, `Roles`, or `Users`.

Type: List of String values

Update requires: No interruption (p. 120)

`Users`

The names of users for whom you want to add the policy.

Required: Conditional. You must specify at least one of the following properties: `Groups`, `Roles`, or `Users`.

Type: List of String values

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

IAM Policy with policy group

JSON

```
{
   "Type" : "AWS::IAM::Policy",
   "Properties" : {
      "PolicyName" : "CFNUsers",
      "PolicyDocument" : {
         "Version" : "2012-10-17",
         "Statement": [ {
         "Effect"   : "Allow",
         "Action"   : [
            "cloudformation:Describe*",
            "cloudformation:List*",
            "cloudformation:Get*"
         ],
         "Resource" : "*"
         } ]
      },
      "Groups" : [ { "Ref" : "CFNUserGroup" } ]
   }
}
```

YAML

```
Type: AWS::IAM::Policy
Properties:
  PolicyName: "CFNUsers"
```

```
  PolicyDocument:
    Version: "2012-10-17"
    Statement:
      -
        Effect: "Allow"
        Action:
          - "cloudformation:Describe*"
          - "cloudformation:List*"
          - "cloudformation:Get*"
        Resource: "*"
  Groups:
    -
      Ref: "CFNUserGroup"
```

IAM Policy with specified role

JSON

```
{
   "Type": "AWS::IAM::Policy",
   "Properties": {
      "PolicyName": "root",
      "PolicyDocument": {
         "Version" : "2012-10-17",
         "Statement": [
            { "Effect": "Allow", "Action": "*", "Resource": "*" }
         ]
      },
      "Roles": [ { "Ref": "RootRole" } ]
   }
}
```

YAML

```
Type: AWS::IAM::Policy
Properties:
  PolicyName: "root"
  PolicyDocument:
    Version: "2012-10-17"
    Statement:
      -
        Effect: "Allow"
        Action: "*"
        Resource: "*"
  Roles:
    -
      Ref: "RootRole"
```

IAM Policies

`Policies` is a property of the AWS::IAM::Role (p. 1670), AWS::IAM::Group (p. 1658), and AWS::IAM::User (p. 1678) resources. The `Policies` property describes what actions are allowed on what resources. For more information about IAM policies, see Overview of Policies and AWS IAM Policy Reference in the *IAM User Guide*.

Syntax

JSON

```
{
```

```
  "PolicyDocument" : JSON,
  "PolicyName" : String
}
```

YAML

```
PolicyDocument: JSON
PolicyName: String
```

Properties

`PolicyDocument`

A policy document that describes what actions are allowed on which resources.

Required: Yes

Type: JSON object

Update requires: No interruption (p. 120)

`PolicyName`

The name of the policy.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

AWS::IAM::Role

Creates an AWS Identity and Access Management (IAM) role. Use an IAM role to enable applications running on an EC2 instance to securely access your AWS resources.

For more information about IAM roles, see Working with Roles in the *AWS Identity and Access Management User Guide*.

Topics

- Syntax (p. 1670)
- Properties (p. 1671)
- Return Values (p. 1673)
- Template Examples (p. 1673)
- See Also (p. 1676)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type": "AWS::IAM::Role",
  "Properties": {
```

```
    "AssumeRolePolicyDocument (p. 1671)": { JSON },
    "ManagedPolicyArns": [ String, ... ],
    "MaxSessionDuration (p. 1671)": Integer,
    "Path (p. 1672)": String,
    "Policies (p. 1672)": [ Policies, ... ],
    "RoleName": String
  }
}
```

YAML

```
Type: AWS::IAM::Role
Properties:
  AssumeRolePolicyDocument (p. 1671):
    JSON object
  ManagedPolicyArns:
    - String
  MaxSessionDuration (p. 1671): Integer
  Path (p. 1672): String
  Policies (p. 1672):
    - Policies
  RoleName: String
```

Properties

`AssumeRolePolicyDocument`

The trust policy that is associated with this role. You can associate only one assume role policy with a role. For an example of an assume role policy, see Template Examples (p. 1673). For more information about the elements that you can use in an IAM policy, see IAM Policy Elements Reference in the *IAM User Guide*.

Required: Yes

Type: A JSON policy document

> **Note**
> AWS Identity and Access Management (IAM) requires that policies be in JSON format. However, for templates formatted in YAML, you can create an IAM policy in either JSON or YAML format. AWS CloudFormation always converts a policy to JSON format before submitting it to IAM.

Update requires: No interruption (p. 120)

`ManagedPolicyArns`

One or more managed policy ARNs to attach to this role.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`MaxSessionDuration`

The maximum session duration (in seconds) for the specified role. Anyone who uses the AWS CLI or API to assume the role can specify the duration using the optional `DurationSeconds` API parameter or `duration-seconds` CLI parameter. Minimum value of 3600. Maximum value of 43200.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Path`

The path associated with this role. For information about IAM paths, see Friendly Names and Paths in *IAM User Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Policies`

The policies to associate with this role. For sample templates, see Template Examples (p. 1673).

> **Important**
> The name of each policy for a role, user, or group must be unique. If you don't, updates to the IAM role will fail.
>
> **Note**
> If an external policy (such as `AWS::IAM::Policy` or `AWS::IAM::ManagedPolicy`) has a `Ref` to a role and if a resource (such as `AWS::ECS::Service`) also has a `Ref` to the same role, add a `DependsOn` attribute to the resource to make the resource depend on the external policy. This dependency ensures that the role's policy is available throughout the resource's lifecycle. For example, when you delete a stack with an `AWS::ECS::Service` resource, the `DependsOn` attribute ensures that AWS CloudFormation deletes the `AWS::ECS::Service` resource before deleting its role's policy.

Required: No

Type: List of IAM Policies (p. 1669)

Update requires: No interruption (p. 120)

`RoleName`

A name for the IAM role. For valid values, see the `RoleName` parameter for the `CreateRole` action in the *IAM API Reference*. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the group name.

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

If you specify a name, you must specify the `CAPABILITY_NAMED_IAM` value to acknowledge your template's capabilities. For more information, see Acknowledging IAM Resources in AWS CloudFormation Templates (p. 15).

> **Warning**
> Naming an IAM resource can cause an unrecoverable error if you reuse the same template in multiple regions. To prevent this, we recommend using `Fn::Join` and `AWS::Region` to create a region-specific name, as in the following example: `{"Fn::Join": ["", [{"Ref": "AWS::Region"}, {"Ref": "MyResourceName"}]]}`.

Required: No

Type: String

Update requires: Replacement (p. 121)

Notes on policies for IAM roles

For general information about IAM policies and policy documents, see How to Write a Policy in *IAM User Guide*.

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "RootRole" }
```

For the IAM::Role with the logical ID "RootRole", `Ref` will return the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

Returns the Amazon Resource Name (ARN) for the instance profile. For example:

```
{"Fn::GetAtt" : ["MyRole", "Arn"] }
```

This will return a value such as `“arn:aws:iam::1234567890:role/MyRole-AJJHDSKSDF”`.

`RoleId`

Returns the stable and unique string identifying the role. For example, `AIDAJQABLZS4A3QDU576Q`.

For more information about IDs, see IAM Identifiers in the *IAM User Guide*.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Template Examples

IAM Role with Embedded Policy and Instance Profiles

This example shows an embedded Policy in the IAM::Role. The policy is specified inline in the IAM::Role Policies property.

JSON

```
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "RootRole": {
         "Type": "AWS::IAM::Role",
         "Properties": {
            "AssumeRolePolicyDocument": {
               "Version" : "2012-10-17",
               "Statement": [ {
                  "Effect": "Allow",
                  "Principal": {
                     "Service": [ "ec2.amazonaws.com" ]
                  },
```

```
                  "Action": [ "sts:AssumeRole" ]
               } ]
            },
            "Path": "/",
            "Policies": [ {
               "PolicyName": "root",
               "PolicyDocument": {
                  "Version" : "2012-10-17",
                  "Statement": [ {
                     "Effect": "Allow",
                     "Action": "*",
                     "Resource": "*"
                  } ]
               }
               } ]
            }
      },
      "RootInstanceProfile": {
         "Type": "AWS::IAM::InstanceProfile",
         "Properties": {
            "Path": "/",
            "Roles": [ {
               "Ref": "RootRole"
            } ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  RootRole:
    Type: "AWS::IAM::Role"
    Properties:
      AssumeRolePolicyDocument:
        Version: "2012-10-17"
        Statement:
          -
            Effect: "Allow"
            Principal:
              Service:
                - "ec2.amazonaws.com"
            Action:
              - "sts:AssumeRole"
      Path: "/"
      Policies:
        -
          PolicyName: "root"
          PolicyDocument:
            Version: "2012-10-17"
            Statement:
              -
                Effect: "Allow"
                Action: "*"
                Resource: "*"
  RootInstanceProfile:
    Type: "AWS::IAM::InstanceProfile"
    Properties:
      Path: "/"
      Roles:
        -
          Ref: "RootRole"
```

IAM Role with External Policy and Instance Profiles

In this example, the Policy and InstanceProfile resources are specified externally to the IAM Role. They refer to the role by specifying its name, "RootRole", in their respective Roles properties.

JSON

```
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "RootRole": {
         "Type": "AWS::IAM::Role",
         "Properties": {
            "AssumeRolePolicyDocument": {
               "Version" : "2012-10-17",
               "Statement": [ {
                  "Effect": "Allow",
                  "Principal": {
                     "Service": [ "ec2.amazonaws.com" ]
                  },
                  "Action": [ "sts:AssumeRole" ]
               } ]
            },
            "Path": "/"
         }
      },
      "RolePolicies": {
         "Type": "AWS::IAM::Policy",
         "Properties": {
            "PolicyName": "root",
            "PolicyDocument": {
               "Version" : "2012-10-17",
               "Statement": [ {
                  "Effect": "Allow",
                  "Action": "*",
                  "Resource": "*"
               } ]
            },
            "Roles": [ {
               "Ref": "RootRole"
            } ]
         }
      },
      "RootInstanceProfile": {
         "Type": "AWS::IAM::InstanceProfile",
         "Properties": {
            "Path": "/",
            "Roles": [ {
               "Ref": "RootRole"
            } ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  RootRole:
    Type: "AWS::IAM::Role"
    Properties:
      AssumeRolePolicyDocument:
        Version: "2012-10-17"

          Ref: "RootRole"
```

See Also

- AWS Identity and Access Management Template Snippets (p. 394)
- AWS::IAM::InstanceProfile (p. 1660)

AWS::IAM::ServiceLinkedRole

The `AWS::IAM::ServiceLinkedRole` resource creates a service-linked role in AWS Identity and Access Management (IAM). A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles are predefined by the service and include all the permissions that the service requires to call other AWS services on your behalf. The linked service also defines how you create, modify, and delete a service-linked role. For more information, see CreateServiceLinkedRole in the *IAM API Reference* or Using Service-Linked Roles in the *IAM User Guide*.

Topics

- Syntax (p. 1676)
- Properties (p. 1677)
- Examples (p. 1678)
- See Also (p. 1678)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Type" : "AWS::IAM::ServiceLinkedRole",
  "Properties" : {

    "AWSServiceName" : String,
    "CustomSuffix" : String,
    "Description" : String
  }
}
```

YAML

```
Type: "AWS::IAM::ServiceLinkedRole"
Properties:
  AWSServiceName: String
  CustomSuffix: String
  Description: String
```

Properties

`AWSServiceName`

The service principal for the AWS service to which this role is attached. You use a string similar to a URL but without the `http://` in front. For example: `elasticbeanstalk.amazonaws.com`.

Service principals are unique and case sensitive. To find the exact service principal for your service-linked role, see AWS Services That Work with IAM in the *IAM User Guide*. Look for the services that have **Yes** in the **Service-Linked Role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`CustomSuffix`

A string that you provide, which is combined with the service-provided prefix to form the complete role name. If you make multiple requests for the same service, then you must supply a different `CustomSuffix` for each request. Otherwise the request fails with a duplicate role name error. For example, you could add `-1` or `-debug` to the suffix.

Some services do not support the `CustomSuffix` parameter. If you provide an optional suffix and the operation fails, try the operation again without the suffix.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Description`

The description of the role.

Required: No

Type: String

Update requires: No interruption (p. 120)

Examples

Create an IAM Service-Linked Role for Auto Scaling

The following example creates a service-linked role that can be assumed by the Auto Scaling service.

YAML

```
---
Description: "SLR resource create test - Auto Scaling"
Resources:
  BasicSLR:
    Type: "AWS::IAM::ServiceLinkedRole"
    Properties:
      AWSServiceName: "autoscaling.amazonaws.com"
      Description: "Test SLR description"
      CustomSuffix: "TestSuffix"
Outputs:
  SLRId:
    Value: !Ref BasicSLR
```

See Also

- CreateServiceLinkedRole in the *IAM API Reference*
- Using Service-Linked Roles in the *IAM User Guide*

AWS::IAM::User

The `AWS::IAM::User` type creates a user.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type": "AWS::IAM::User",
  "Properties": {
    "Groups (p. 1679)": [ String, ... ],
    "LoginProfile (p. 1679)": LoginProfile Type,
    "ManagedPolicyArns": [ String, ... ],
    "Path (p. 1679)": String,
    "Policies (p. 1679)": [ Policies, ... ],
    "UserName": String
  }
}
```

YAML

```
Type: AWS::IAM::User
Properties:
  Groups (p. 1679):
    - String
  LoginProfile (p. 1679):
    LoginProfile Type
  ManagedPolicyArns:
    - String
  Path (p. 1679): String
```

```
  Policies (p. 1679):
    - Policies
  UserName: String
```

Properties

`Groups`

A name of a group to which you want to add the user.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`LoginProfile`

Creates a login profile so that the user can access the AWS Management Console.

Required: No

Type: IAM User LoginProfile (p. 1680)

Update requires: No interruption (p. 120)

`ManagedPolicyArns`

One or more managed policy ARNs to attach to this user.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Path`

The path for the user name. For more information about paths, see IAM Identifiers in the *IAM User Guide*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Policies`

The policies to associate with this user. For information about policies, see Overview of IAM Policies in the *IAM User Guide*.

> **Note**
> If you specify multiple polices, specify unique values for the policy name. If you don't, updates to the IAM user will fail.

Required: No

Type: List of IAM Policies (p. 1669)

Update requires: No interruption (p. 120)

`UserName`

A name for the IAM user. For valid values, see the `UserName` parameter for the `CreateUser` action in the *IAM API Reference*. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the user name.

Important
If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

If you specify a name, you must specify the `CAPABILITY_NAMED_IAM` value to acknowledge your template's capabilities. For more information, see Acknowledging IAM Resources in AWS CloudFormation Templates (p. 15).

Warning
Naming an IAM resource can cause an unrecoverable error if you reuse the same template in multiple regions. To prevent this, we recommend using `Fn::Join` and `AWS::Region` to create a region-specific name, as in the following example: `{"Fn::Join": ["", [{"Ref": "AWS::Region"}, {"Ref": "MyResourceName"}]]}`.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

Specifying this resource ID to the intrinsic Ref function will return the `UserName`. For example: `mystack-myuser-1CCXAFG2H2U4D`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

Returns the Amazon Resource Name (ARN) for the specified AWS::IAM::User resource. For example: `arn:aws:iam::123456789012:user/mystack-myuser-1CCXAFG2H2U4D`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Template Examples

To view AWS::IAM::User snippets, see: Declaring an IAM User Resource (p. 394).

IAM User LoginProfile

`LoginProfile` is a property of the AWS::IAM::User (p. 1678) resource that creates a login profile for users so that they can access the AWS Management Console.

Syntax

JSON

```
{
  "Password" : String,
```

```
  "PasswordResetRequired" : Boolean
}
```

YAML

```
Password: String
PasswordResetRequired: Boolean
```

Properties

`Password`

The password for the user.

Required: Yes

Type: String

`PasswordResetRequired`

Specifies whether the user is required to set a new password the next time the user logs in to the AWS Management Console.

Required: No

Type: Boolean

AWS::IAM::UserToGroupAddition

The `AWS::IAM::UserToGroupAddition` type adds AWS Identity and Access Management (IAM) users to a group.

This type supports updates. For more information about updating stacks, see AWS CloudFormation Stacks Updates (p. 120).

Topics

- Syntax (p. 1681)
- Properties (p. 1682)
- Return Value (p. 1682)
- Template Examples (p. 1682)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type": "AWS::IAM::UserToGroupAddition",
   "Properties": {
      "GroupName (p. 1682)": String,
      "Users (p. 1682)": [ User1, ... ]
   }
}
```

YAML

```
Type: AWS::IAM::UserToGroupAddition
Properties:
  GroupName (p. 1682): String
  Users (p. 1682):
    - User1
```

Properties

`GroupName`

The name of group to add users to.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Users`

Required: Yes

Type: List of users

Update requires: No interruption (p. 120)

Return Value

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyUserToGroupAddition" }
```

For the `AWS::IAM::UserToGroupAddition` with the logical ID "MyUserToGroupAddition", `Ref` will return the AWS resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Template Examples

To view `AWS::IAM::UserToGroupAddition` snippets, see Adding Users to a Group (p. 398).

Amazon Inspector Resource Types Reference

This section contains reference information for all Amazon Inspector resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::Inspector::data-type-name
```

Topics

- AWS::Inspector::AssessmentTarget (p. 1683)

- AWS::Inspector::AssessmentTemplate (p. 1684)
- AWS::Inspector::ResourceGroup (p. 1687)

AWS::Inspector::AssessmentTarget

The `AWS::Inspector::AssessmentTarget` resource creates an Amazon Inspector assessment target - a resource that contains information about an Amazon Inspector application.

Topics

- Syntax (p. 1683)
- Properties (p. 1683)
- Return Values (p. 1684)
- Examples (p. 1684)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Inspector::AssessmentTarget",
  "Properties" : {
    "AssessmentTargetName" : String,
    "ResourceGroupArn" : String
  }
}
```

YAML

```
Type: AWS::Inspector::AssessmentTarget
Properties:
  AssessmentTargetName: String
  ResourceGroupArn: String
```

Properties

`AssessmentTargetName`

The name of the Amazon Inspector assessment target.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ResourceGroupArn`

The ARN that specifies the resource group that is associated with the assessment target.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Values

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The Amazon Resource Name (ARN) that specifies the assessment target that is created.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Declaring an Amazon Inspector Assessment Target Resource

The following example shows how to declare an AWS::Inspector::AssessmentTarget resource to create an Amazon Inspector assessment target.

JSON

```
"myassessmenttarget": {
  "Type": "AWS::Inspector::AssessmentTarget",
  "Properties": {
    "AssessmentTargetName" : "MyAssessmentTarget",
    "ResourceGroupArn" : "arn:aws:inspector:us-west-2:123456789012:resourcegroup/0-
AB6DMKnv"
  }
}
```

YAML

```
myassessmenttarget:
  Type: AWS::Inspector::AssessmentTarget
  Properties:
    AssessmentTargetName : "MyAssessmentTarget"
    ResourceGroupArn : "arn:aws:inspector:us-west-2:123456789012:resourcegroup/0-AB6DMKnv"
```

AWS::Inspector::AssessmentTemplate

The `AWS::Inspector::AssessmentTemplate` resource creates an Amazon Inspector assessment template - a resource that contains information about an Amazon Inspector assessment template.

Topics

- Syntax (p. 1684)
- Properties (p. 1685)
- Return Values (p. 1686)
- Examples (p. 1686)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Inspector::AssessmentTemplate",
  "Properties" : {
    "AssessmentTargetArn" : String,
    "DurationInSeconds" : Integer,
    "AssessmentTemplateName" : String,
    "RulesPackageArns" : [ String, ... ],
    "UserAttributesForFindings" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: AWS::Inspector::AssessmentTemplate
Properties:
  AssessmentTargetArn: String
  DurationInSeconds: Integer
  AssessmentTemplateName: String
  RulesPackageArns:
    - String
  UserAttributesForFindings:
    - Resource Tag
```

Properties

`AssessmentTargetArn`

The ARN of the assessment target that corresponds to this assessment template.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`DurationInSeconds`

The duration in seconds specified for this assessment tempate. The default value is 3600 seconds (one hour). The maximum value is 86400 seconds (one day).

Required: Yes

Type: Integer

Update requires: Replacement (p. 121)

`AssessmentTemplateName`

The name of the assessment template.

Required: No

Type: String

Update requires: Replacement (p. 121)

`RulesPackageArns`

The rules packages that are specified for this assessment template.

Required: Yes

Type: List of String values

Update requires: Replacement (p. 121)

`UserAttributesForFindings`

The user-defined attributes that are assigned to every generated finding from the assessment run that uses this assessment template.

Required: No

Type: List of Resource Tag (p. 2258)

Update requires: Replacement (p. 121)

Return Values

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The Amazon Resource Name (ARN) that specifies the assessment template that is created.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Declaring an Amazon Inspector Assessment Template Resource

The following example shows how to declare an AWS::Inspector::AssessmentTemplate resource to create an Amazon Inspector assessment template.

JSON

```
"myassessmenttemplate": {
    "Type": "AWS::Inspector::AssessmentTemplate",
    "Properties": {
        "AssessmentTargetArn": "arn:aws:inspector:us-west-2:123456789012:target/0-
nvgVhaxX",
        "DurationInSeconds": 180,
        "AssessmentTemplateName": "MyAssessmentTemplate",
        "RulesPackageArns": [
            "arn:aws:inspector:us-west-2:758058086616:rulespackage/0-11B9DBXp"
        ],
        "UserAttributesForFindings": [
            {
                "Key": "Example",
                "Value": "example"
            }
        ]
    }
}
```

YAML

```
myassessmenttemplate:
  Type: AWS::Inspector::AssessmentTemplate
  Properties:
    AssessmentTargetArn: "arn:aws:inspector:us-west-2:123456789012:target/0-nvgVhaxX"
    AssessmentTemplateName: MyAssessmentTemplate
    DurationInSeconds: 180
    RulesPackageArns:
      - "arn:aws:inspector:us-west-2:758058086616:rulespackage/0-11B9DBXp"
    UserAttributesForFindings:
      -
        Key: Example
        Value: example
```

AWS::Inspector::ResourceGroup

The `AWS::Inspector::ResourceGroup` resource is used to create Amazon Inspector resource groups. A resource group defines a set of tags that, when queried, identify the AWS resources that make up the assessment target.

Topics

- Syntax (p. 1687)
- Properties (p. 1687)
- Return Values (p. 1688)
- Examples (p. 1688)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Inspector::ResourceGroup",
  "Properties" : {
    "ResourceGroupTags" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: AWS::Inspector::ResourceGroup
Properties:
  ResourceGroupTags:
    - Resource Tag
```

Properties

`ResourceGroupTags`

The tags (key and value pairs) of the resource group.

Required: Yes

Type: List of Resource Tag (p. 2258)

Update requires: Replacement (p. 121)

Return Values

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The Amazon Resource Name (ARN) that specifies the resource group that is created.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Declaring an Amazon Inspector Assessment Resource Group Resource

The following example shows how to declare an AWS::Inspector::ResourceGroup resource to create an Amazon Inspector resource group.

JSON

```
"myresourcegroup": {
  "Type": "AWS::Inspector::ResourceGroup",
  "Properties": {
    "ResourceGroupTags": [
      {
        "Key": "Name",
        "Value": "example"
      }
    ]
  }
}
```

YAML

```
myresourcegroup:
  Type: "AWS::Inspector::ResourceGroup"
  Properties:
    ResourceGroupTags:
      - Key: "Name"
        Value: "example"
```

AWS IoT Resource Types Reference

This section contains reference information for all AWS IoT resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::IoT::data-type-name
```

Topics

- AWS::IoT::Certificate (p. 1689)
- AWS::IoT::Policy (p. 1691)
- AWS::IoT::PolicyPrincipalAttachment (p. 1693)

- AWS::IoT::Thing (p. 1694)
- AWS::IoT::ThingPrincipalAttachment (p. 1698)
- AWS::IoT::TopicRule (p. 1699)

AWS::IoT::Certificate

Use the `AWS::IoT::Certificate` resource to declare an X.509 certificate.

For information about working with X.509 certificates, see Authentication in AWS IoT in the *AWS IoT Developer Guide*.

Syntax

JSON

```
{
   "Type": "AWS::IoT::Certificate",
   "Properties": {
      "CertificateSigningRequest": String,
      "Status": String
    }
}
```

YAML

```
Type: AWS::IoT::Certificate
  Properties:
    CertificateSigningRequest: String
    Status: String
```

Properties

`CertificateSigningRequest`

The certificate signing request (CSR).

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Status`

The status of the certificate.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When you provide the logical ID of this resource to the `Ref` intrinsic function, `Ref` returns the certificate ID. For example:

```
{ "Ref": "MyCertificate" }
```

A value similar to the following is returned:

```
a1234567b89c012d3e4fg567hij8k9l01mno1p23q45678901rs234567890t1u2
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

Returns the Amazon Resource Name (ARN) for the instance profile. For example:

```
{ "Fn::GetAtt": ["MyCertificate", "Arn"] }
```

A value similar to the following is returned:

```
arn:aws:iot:ap-southeast-2:123456789012:cert/
a1234567b89c012d3e4fg567hij8k9l01mno1p23q45678901rs234567890t1u2
```

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example declares an X.509 certificate and its status.

JSON

```
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "MyCertificate": {
         "Type": "AWS::IoT::Certificate",
         "Properties": {
            "CertificateSigningRequest": {
               "Ref": "CSRParameter"
            },
            "Status": {
               "Ref": "StatusParameter"
            }
         }
      }
   },
   "Parameters": {
      "CSRParameter": {
         "Type": "String"
      },
      "StatusParameter": {
         "Type": "String"
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  MyCertificate:
    Type: AWS::IoT::Certificate
    Properties:
      CertificateSigningRequest:
        Ref: "CSRParameter"
      Status:
        Ref: "StatusParameter"
Parameters:
  CSRParameter:
    Type: "String"
  StatusParameter:
    Type: "String"
```

AWS::IoT::Policy

Use the `AWS::IoT::Policy` resource to declare an AWS IoT policy.

For information about working with AWS IoT policies, see Authorization in the *AWS IoT Developer Guide*.

Syntax

JSON

```
{
   "Type": "AWS::IoT::Policy",
   "Properties": {
      "PolicyDocument": JSON object,
      "PolicyName": String
    }
}
```

YAML

```
Type: AWS::IoT::Policy
Properties:
  PolicyDocument: JSON object
  PolicyName: String
```

Properties

`PolicyDocument`

The JSON document that describes the policy.

Required: Yes

Type: JSON object

Update requires: Replacement (p. 121)

`PolicyName`

The name (the physical ID) of the AWS IoT policy.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you provide the logical ID of this resource to the `Ref` intrinsic function, `Ref` returns the policy name. For example:

```
{ "Ref": "MyPolicy" }
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The Amazon Resource Name (ARN) of the AWS IoT policy, such as `arn:aws:iot:us-east-2:123456789012:policy/MyPolicy`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example declares an AWS IoT policy.

JSON

```
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "MyPolicy": {
         "Type": "AWS::IoT::Policy",
         "Properties": {
            "PolicyName": {
               "Ref": "NameParameter"
            },
            "PolicyDocument": {
               "Version": "2012-10-17",
               "Statement": [{
                  "Effect": "Allow",
                  "Action": [
                     "iot:Connect"
                  ],
                  "Resource": [
                     "*"
                  ]
               }]
            }
         }
      }
   },
   "Parameters": {
      "NameParameter": {
         "Type": "String"
      }
```

```
    }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  MyPolicy:
    Type: AWS::IoT::Policy
    Properties:
      PolicyName:
        Ref: "NameParameter"
      PolicyDocument:
        Version: "2012-10-17"
        Statement:
          -
            Effect: "Allow"
            Action:
              - "iot:Connect"
            Resource:
              - "*"
Parameters:
  NameParameter:
    Type: "String"
```

AWS::IoT::PolicyPrincipalAttachment

Use the `AWS::IoT::PolicyPrincipalAttachment` resource to attach an AWS IoT policy to a principal (an X.509 certificate or other credential).

For information about working with AWS IoT policies and principals, see Authorization in the *AWS IoT Developer Guide*.

Syntax

JSON

```
{
   "Type": "AWS::IoT::PolicyPrincipalAttachment",
   "Properties": {
      "PolicyName": String,
      "Principal": String
    }
}
```

YAML

```
Type: AWS::IoT::PolicyPrincipalAttachment
  Properties:
    PolicyName: String
    Principal: String
```

Properties

`PolicyName`

The name of the policy.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Principal`

The principal, which can be a certificate ARN (as returned from the `CreateCertificate` operation) or an Amazon Cognito ID.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Example

The following example attaches a policy to a principal.

JSON

```
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "MyPolicyPrincipalAttachment": {
         "Type": "AWS::IoT::PolicyPrincipalAttachment",
         "Properties": {
            "PolicyName": {
               "Ref": "NameParameter"
            },
            "Principal": "arn:aws:iot:ap-southeast-2:123456789012:cert/
a1234567b89c012d3e4fg567hij8k9l01mno1p23q45678901rs234567890t1u2"
         }
      }
   },
   "Parameters": {
      "NameParameter": {
         "Type": "String"
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  MyPolicyPrincipalAttachment:
    Type: AWS::IoT::PolicyPrincipalAttachment
    Properties:
      PolicyName:
        Ref: "NameParameter"
      Principal: "arn:aws:iot:ap-southeast-2:123456789012:cert/
a1234567b89c012d3e4fg567hij8k9l01mno1p23q45678901rs234567890t1u2"
Parameters:
  NameParameter:
    Type: "String"
```

AWS::IoT::Thing

Use the `AWS::IoT::Thing` resource to declare an AWS IoT thing.

For information about working with things, see How AWS IoT Works and Device Registry for AWS IoT in the *AWS IoT Developer Guide*.

Syntax

JSON

```
{
   "Type": "AWS::IoT::Thing",
   "Properties": {
      "AttributePayload": AttributePayload (p. 1697)
      "ThingName": String
    }
}
```

YAML

```
Type: AWS::IoT::Thing
Properties:
  AttributePayload:
    AttributePayload (p. 1697)
  ThingName: String
```

Properties

`AttributePayload`

The attribute payload.

Required: No

Type: AWS IoT Thing AttributePayload (p. 1697)

Update requires: No interruption (p. 120)

`ThingName`

The name (the physical ID) of the AWS IoT thing.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Value

Ref

When you provide the logical ID of this resource to the `Ref` intrinsic function, `Ref` returns the thing name. For example:

```
{ "Ref": "MyThing" }
```

For a stack named `MyStack`, a value similar to the following is returned:

```
MyStack-MyThing-AB1CDEFGHIJK
```

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example declares a thing and the values of its attributes.

JSON

```
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "MyThing": {
         "Type": "AWS::IoT::Thing",
         "Properties": {
            "ThingName": {
               "Ref": "NameParameter"
            },
            "AttributePayload": {
               "Attributes": {
                  "myAttributeA": {
                     "Ref": "MyAttributeValueA"
                  },
                  "myAttributeB": {
                     "Ref": "MyAttributeValueB"
                  },
                  "myAttributeC": {
                     "Ref": "MyAttributeValueC"
                  }
               }
            }
         }
      }
   },
   "Parameters": {
      "NameParameter": {
         "Type": "String"
      },
      "MyAttributeValueA": {
         "Type": "String",
         "Default": "myStringA123"
      },
      "MyAttributeValueB": {
         "Type": "String",
         "Default": "myStringB123"
      },
      "MyAttributeValueC": {
         "Type": "String",
         "Default": "myStringC123"
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  MyThing:
    Type: AWS::IoT::Thing
    Properties:
      ThingName:
        Ref: "NameParameter"
      AttributePayload:
        Attributes:
```

```
          myAttributeA:
            Ref: "MyAttributeValueA"
          myAttributeB:
            Ref: "MyAttributeValueB"
          myAttributeC:
            Ref: "MyAttributeValueC"
Parameters:
  NameParameter:
    Type: "String"
  MyAttributeValueA:
    Type: "String"
    Default: "myStringA123"
  MyAttributeValueB:
    Type: "String"
    Default: "myStringB123"
  MyAttributeValueC:
    Type: "String"
    Default: "myStringC123"
```

AWS IoT Thing AttributePayload

The `AttributePayload` property specifies up to three attributes for an AWS IoT as key–value pairs. `AttributePayload` is a property of the AWS::IoT::Thing (p. 1694) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Attributes" : { String:String, ... }
}
```

YAML

```
Attributes:
  String: String
```

Properties

`Attributes`

A string that contains up to three key–value pairs. Maximum length of 800. Duplicates not allowed.

Required: No

Type: String to string map

Update requires: No interruption (p. 120)

Example

The following example declares an attribute payload with three attributes.

JSON

```
"AttributePayload": {
    "Attributes": {
        "myAttributeA": {
```

```
            "Ref": "MyAttributeValueA"
        },
        "myAttributeB": {
            "Ref": "MyAttributeValueB"
        },
        "myAttributeC": {
            "Ref": "MyAttributeValueC"
        }
    }
}
```

YAML

```
AttributePayload:
  Attributes:
    myAttributeA:
      Ref: "MyAttributeValueA"
    myAttributeB:
      Ref: "MyAttributeValueB"
    myAttributeC:
      Ref: "MyAttributeValueC"
```

AWS::IoT::ThingPrincipalAttachment

Use the `AWS::IoT::ThingPrincipalAttachment` resource to attach a principal (an X.509 certificate or another credential) to a thing.

For information about working with AWS IoT things and principals, see Authorization in the *AWS IoT Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type": "AWS::IoT::ThingPrincipalAttachment",
   "Properties": {
      "Principal": String,
      "ThingName": String
    }
}
```

YAML

```
Type: AWS::IoT::ThingPrincipalAttachment
Properties:
  Principal: String
  ThingName: String
```

Properties

`Principal`

The principal, which can be a certificate ARN (as returned from the `CreateCertificate` operation) or an Amazon Cognito ID.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ThingName`

The name of the AWS IoT thing.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Example

The following example attaches a principal to a thing.

JSON

```
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "MyThingPrincipalAttachment": {
         "Type": "AWS::IoT::ThingPrincipalAttachment",
         "Properties": {
            "ThingName": {
               "Ref": "NameParameter"
            },
            "Principal": "arn:aws:iot:ap-southeast-2:123456789012:cert/
a1234567b89c012d3e4fg567hij8k9l01mno1p23q45678901rs234567890t1u2"
         }
      }
   },
   "Parameters": {
      "NameParameter": {
         "Type": "String"
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  MyThingPrincipalAttachment:
    Type: AWS::IoT::ThingPrincipalAttachment
    Properties:
      ThingName:
        Ref: "NameParameter"
      Principal: "arn:aws:iot:ap-southeast-2:123456789012:cert/
a1234567b89c012d3e4fg567hij8k9l01mno1p23q45678901rs234567890t1u2"
Parameters:
  NameParameter:
    Type: "String"
```

AWS::IoT::TopicRule

Use the `AWS::IoT::TopicRule` resource to declare an AWS IoT rule.

For information about working with AWS IoT rules, see Rules for AWS IoT in the *AWS IoT Developer Guide*.

Syntax

JSON

```
{
   "Type": "AWS::IoT::TopicRule",
   "Properties": {
      "RuleName": String,
      "TopicRulePayload": TopicRulePayLoad
   }
}
```

YAML

```
Type: AWS::IoT::TopicRule
Properties:
  RuleName: String
  TopicRulePayload: TopicRulePayLoad
```

Properties

`RuleName`

The name (the physical ID) of the AWS IoT rule.

Required: No

Type: String

Update requires: Replacement (p. 121)

`TopicRulePayload`

The actions associated with the AWS IoT rule.

Required: Yes

Type: `TopicRulePayload` (p. 1717) object

Update requires: No interruption (p. 120)

Return Values

Ref

When you provide the logical ID of this resource to the `Ref` intrinsic function, `Ref` returns the topic rule name. For example:

```
{ "Ref": "MyTopicRule" }
```

For a stack named `My-Stack` (the – character is omitted), a value similar to the following is returned:

```
MyStackMyTopicRule12ABC3D456EFG
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The Amazon Resource Name (ARN) of the AWS IoT rule, such as `arn:aws:iot:us-east-2:123456789012:rule/MyIoTRule`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example declares an AWS IoT rule.

JSON

```
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "MyTopicRule": {
         "Type": "AWS::IoT::TopicRule",
         "Properties": {
            "RuleName": {
               "Ref": "NameParameter"
            },
            "TopicRulePayload": {
               "RuleDisabled": "true",
               "Sql": "SELECT temp FROM 'SomeTopic' WHERE temp > 60",
               "Actions": [{
                  "S3": {
                     "BucketName": {
                        "Ref": "MyBucket"
                     },
                     "RoleArn": {
                        "Fn::GetAtt": ["MyRole", "Arn"]
                     },
                     "Key": "MyKey.txt"
                  }
               }]
            }
         }
      },
      "MyBucket": {
         "Type": "AWS::S3::Bucket",
         "Properties": {}
      },
      "MyRole": {
         "Type": "AWS::IAM::Role",
         "Properties": {
            "AssumeRolePolicyDocument": {
               "Version": "2012-10-17",
               "Statement": [{
                  "Effect": "Allow",
                  "Principal": {
                     "Service": [
                        "iot.amazonaws.com"
                     ]
                  },
                  "Action": [
                     "sts:AssumeRole"
                  ]
               }]
            }
         }
      }
   },
```

```
   "Parameters": {
      "NameParameter": {
         "Type": "String"
      }
   }
}
```

YAML

```

```

AWS IoT TopicRule Action

`Action` is a property of the `TopicRulePayload` property that describes an action associated with an AWS IoT rule. For more information, see Rules for AWS IoT.

Syntax

JSON

```
{
  "CloudwatchAlarm": CloudwatchAlarm Action,
  "CloudwatchMetric": CloudwatchMetric Action,
```

```
  "DynamoDB": DynamoDB Action,
  "DynamoDBv2": DynamoDBv2 Action,
  "Elasticsearch": Elasticsearch Action,
  "Firehose": Firehose Action,
  "Kinesis": Kinesis Action,
  "Lambda": Lambda Action,
  "Republish": Republish Action,
  "S3": S3 Action,
  "Sns": Sns Action,
  "Sqs": Sqs Action
}
```

YAML

```
CloudwatchAlarm:
  CloudwatchAlarm Action
CloudwatchMetric:
  CloudwatchMetric Action
DynamoDB:
  DynamoDB Action
DynamoDBv2:
  DynamoDBv2 Action
Elasticsearch:
  Elasticsearch Action
Firehose:
  Firehose Action
Kinesis:
  Kinesis Action
Lambda:
  Lambda Action
Republish:
  Republish Action
S3:
  S3 Action
Sns:
  Sns Action
Sqs:
  Sqs Action
```

Properties

`CloudwatchAlarm`

Changes the state of a CloudWatch alarm.

Required: No

Type: AWS IoT TopicRule CloudwatchAlarmAction (p. 1705)

`CloudwatchMetric`

Captures a CloudWatch metric.

Required: No

Type: AWS IoT TopicRule CloudwatchMetricAction (p. 1706)

`DynamoDB`

Writes data to a DynamoDB table.

Required: No

Type: AWS IoT TopicRule DynamoDBAction (p. 1707)

`DynamoDBv2`

Writes data to a DynamoDB table.

Required: No

Type: AWS IoT TopicRule DynamoDBv2Action (p. 1709)

`Elasticsearch`

Writes data to an Elasticsearch domain.

Required: No

Type: AWS IoT TopicRule ElasticsearchAction (p. 1710)

`Firehose`

Writes data to a Kinesis Data Firehose stream.

Required: No

Type: AWS IoT TopicRule FirehoseAction (p. 1711)

`Kinesis`

Writes data to an Kinesis stream.

Required: No

Type: AWS IoT TopicRule KinesisAction (p. 1712)

`Lambda`

Invokes a Lambda function.

Required: No

Type: AWS IoT TopicRule LambdaAction (p. 1712)

`Republish`

Publishes data to an MQ Telemetry Transport (MQTT) topic different from the one currently specified.

Required: No

Type: AWS IoT TopicRule RepublishAction (p. 1713)

`S3`

Writes data to an S3 bucket.

Required: No

Type: AWS IoT TopicRule S3Action (p. 1714)

`Sns`

Publishes data to an SNS topic.

Required: No

Type: AWS IoT TopicRule SnsAction (p. 1715)

`Sqs`

Publishes data to an SQS queue.

Required: No

Type: AWS IoT TopicRule SqsAction (p. 1716)

AWS IoT TopicRule CloudwatchAlarmAction

`CloudwatchAlarm` is a property of the `Actions` property that describes an action that updates a CloudWatch alarm.

Syntax

JSON

```
{
  "AlarmName": String,
  "RoleArn": String,
  "StateReason": String,
  "StateValue": String
}
```

YAML

```
AlarmName: String
RoleArn: String
StateReason: String
StateValue: String
```

Properties

`AlarmName`

The CloudWatch alarm name.

Required: Yes

Type: String

`RoleArn`

The IAM role that allows access to the CloudWatch alarm.

Required: Yes

Type: String

`StateReason`

The reason for the change of the alarm state.

Required: Yes

Type: String

`StateValue`

The value of the alarm state.

Required: Yes

Type: String

AWS IoT TopicRule CloudwatchMetricAction

`CloudwatchMetric` is a property of the `Actions` property that describes an action that captures a CloudWatch metric.

Syntax

JSON

```
{
  "MetricName": String,
  "MetricNamespace": String,
  "MetricTimestamp": String,
  "MetricUnit": String,
  "MetricValue": String,
  "RoleArn": String
}
```

YAML

```
MetricName: String
MetricNamespace: String
MetricTimestamp: String
MetricUnit: String
MetricValue: String
RoleArn: String
```

Properties

`MetricName`

The name of the CloudWatch metric.

Required: Yes

Type: String

`MetricNamespace`

The name of the CloudWatch metric namespace.

Required: Yes

Type: String

`MetricTimestamp`

An optional Unix timestamp.

Required: No

Type: String

`MetricUnit`

The metric unit supported by Amazon CloudWatch.

Required: Yes

Type: String

`MetricValue`

The value to publish to the metric. For example, if you count the occurrences of a particular term such as `Error`, the value will be `1` for each occurrence.

Required: Yes

Type: String

`RoleArn`

The ARN of the IAM role that grants access to the CloudWatch metric.

Required: Yes

Type: String

AWS IoT TopicRule DynamoDBAction

`DynamoDB` is a property of the `Actions` property that describes an AWS IoT action that writes data to a DynamoDB table.

The `HashKeyField`, `RangeKeyField`, and `TableName` values must match the values you used when you initially created the table.

The `HashKeyValue` and `RangeKeyValue` fields use the `${sql-expression}` substitution template syntax. You can specify any valid expression in a `WHERE` or `SELECT` clause. This expression can include JSON properties, comparisons, calculations, and functions, for example:

- The `"HashKeyValue" : "${topic(3)}` field uses the third level of the topic.
- The `"RangeKeyValue" : "${timestamp()}` field uses the timestamp.

Syntax

JSON

```
{
  "HashKeyField": String,
  "HashKeyType": String,
  "HashKeyValue": String,
  "PayloadField": String,
  "RangeKeyField": String,
  "RangeKeyType": String,
  "RangeKeyValue": String,
  "RoleArn": String,
  "TableName": String
}
```

YAML

```
HashKeyField: String
HashKeyType: String
HashKeyValue: String
PayloadField: String
RangeKeyField: String
```

```
RangeKeyType: String
RangeKeyValue: String
RoleArn: String
TableName: String
```

Properties

For more information and valid values, see DynamoDB Action in the *AWS IoT Developer Guide*.

`HashKeyField`

The name of the hash key.

Required: Yes

Type: String

`HashKeyType`

The data type of the hash key (also called the partition key). Valid values are: `"STRING"` or `"NUMBER"`.

Required: No

Type: String

`HashKeyValue`

The value of the hash key.

Required: Yes

Type: String

`PayloadField`

The name of the column in the DynamoDB table that contains the result of the query. You can customize this name.

Required: No

Type: String

`RangeKeyField`

The name of the range key.

Required: No

Type: String

`RangeKeyType`

The data type of the range key (also called the sort key). Valid values are: `"STRING"` or `"NUMBER"`.

Required: No

Type: String

`RangeKeyValue`

The value of the range key.

Required: No

Type: String

`RoleArn`

The ARN of the IAM role that grants access to the DynamoDB table.

Required: Yes

Type: String

`TableName`

The name of the DynamoDB table.

Required: Yes

Type: String

AWS IoT TopicRule DynamoDBv2Action

The `DynamoDBv2Action` property type is a property of the `Actions` property that describes an AWS IoT action that writes data to a DynamoDB table.

`DynamoDBv2Action` is a property of the AWS IoT TopicRule Action (p. 1702) property.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "PutItem" : PutItemInput (p. 1713),
  "RoleArn" : String
}
```

YAML

```
PutItem:
  PutItemInput (p. 1713)
RoleArn: String
```

Properties

For more information, see DynamoDBv2 Action in the *AWS IoT Developer Guide.*.

`PutItem`

Specifies the database table to which to write the item for an AWS IoT topic rule.

Required: No

Type: PutItemInput (p. 1713)

Update requires: No interruption (p. 120)

`RoleArn`

The IAM role that allows access to the DynamoDB table. At a minimum, the role must allow the `dynamoDB:PutItem` IAM action.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS IoT TopicRule ElasticsearchAction

`Elasticsearch` is a property of the `Actions` property that describes an action that writes data to an Elasticsearch domain.

Syntax

JSON

```
{
  "Endpoint": String,
  "Id": String,
  "Index": String,
  "RoleArn": String,
  "Type": String
}
```

YAML

```
Endpoint: String
Id": String
Index": String
RoleArn": String
Type": String
```

Properties

`Endpoint`

The endpoint of your Elasticsearch domain.

Required: Yes

Type: String

`Id`

A unique identifier for the stored data.

Required: Yes

Type: String

`Index`

The Elasticsearch index where the data is stored.

Required: Yes

Type: String

`RoleArn`

The ARN of the IAM role that grants access to Elasticsearch.

Required: Yes

Type: String

`Type`

The type of stored data.

Required: Yes

Type: String

AWS IoT TopicRule FirehoseAction

`Firehose` is a property of the AWS IoT TopicRule Action (p. 1702) property that describes an action that writes data to a Kinesis Data Firehose stream.

Syntax

JSON

```
{
  "DeliveryStreamName": String,
  "RoleArn": String,
  "Separator": String
}
```

YAML

```
DeliveryStreamName: String
RoleArn: String
Separator: String
```

Properties

`DeliveryStreamName`

The delivery stream name.

Required: Yes

Type: String

`RoleArn`

The Amazon Resource Name (ARN) of the IAM role that grants access to the Kinesis Data Firehose stream.

Required: Yes

Type: String

`Separator`

A character separator that's used to separate records written to the Kinesis Data Firehose stream. For valid values, see Firehose Action in the *AWS IoT Developer Guide*.

Required: No

Type: String

AWS IoT TopicRule KinesisAction

`Kinesis` is a property of the `Actions` property that describes an action that writes data to an Kinesis stream.

Syntax

JSON

```
{
  "PartitionKey": String,
  "RoleArn": String,
  "StreamName": String
}
```

YAML

```
PartitionKey: String
RoleArn: String
StreamName: String
```

Properties

`PartitionKey`

The partition key (the grouping of data by shard within an Kinesis stream).

Required: No

Type: String

`RoleArn`

The ARN of the IAM role that grants access to an Kinesis stream.

Required: Yes

Type: String

`StreamName`

The name of the Kinesis stream.

Required: Yes

Type: String

AWS IoT TopicRule LambdaAction

`Lambda` is a property of the `Actions` property that describes an action that invokes a Lambda function.

Syntax

JSON

```
{
  "FunctionArn": String
}
```

YAML

```
FunctionArn: String
```

Properties

`FunctionArn`

The ARN of the Lambda function.

Required: Yes

Type: String

AWS IoT TopicRule PutItemInput

The `PutItemInput` property type specifies the database table for an AWS IoT topic rule.

`PutItemInput` is a property of the DynamoDBv2Action (p. 1709) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "TableName" : String
}
```

YAML

```
TableName: String
```

Properties

`TableName`

The name of the DynamoDB table.

> **Note**
> The MQTT message payload must contain a root-level key that matches the table's primary partition key and a root-level key that matches the table's primary sort key, if one is defined. For more information, see DynamoDBv2 Action in the *AWS IoT Developer Guide.*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

AWS IoT TopicRule RepublishAction

`Republish` is a property of the `Actions` property that describes an action that publishes data to an MQ Telemetry Transport (MQTT) topic different from the one currently specified.

Syntax

JSON

```
{
  "RoleArn": String,
  "Topic": String
}
```

YAML

```
RoleArn: String
Topic: String
```

Properties

`RoleArn`

The ARN of the IAM role that grants publishing access.

Required: Yes

Type: String

`Topic`

The name of the MQTT topic topic different from the one currently specified.

Required: Yes

Type: String

AWS IoT TopicRule S3Action

`S3` is a property of the `Actions` property that describes an action that writes data to an S3 bucket.

Syntax

JSON

```
{
  "BucketName": String,
  "Key": String,
  "RoleArn": String
}
```

YAML

```
BucketName: String
Key: String
RoleArn: String
```

Properties

`BucketName`

The name of the S3 bucket.

Required: Yes

Type: String

`Key`

The object key (the name of an object in the S3 bucket).

Required: Yes

Type: String

`RoleArn`

The ARN of the IAM role that grants access to Amazon S3.

Required: Yes

Type: String

AWS IoT TopicRule SnsAction

`Sns` is a property of the `Actions` property that describes an action that publishes data to an SNS topic.

Syntax

JSON

```
{
  "MessageFormat": String,
  "RoleArn": String,
  "TargetArn": String
}
```

YAML

```
MessageFormat: String
RoleArn: String
TargetArn: String
```

Properties

`MessageFormat`

The format of the published message. Amazon SNS uses this setting to determine whether it should parse the payload and extract the platform-specific bits from the payload.

For more information, see Appendix: Message and JSON Formats in the *Amazon Simple Notification Service Developer Guide*.

Required: No

Type: String

`RoleArn`

The ARN of the IAM role that grants access to Amazon SNS.

Required: Yes

Type: String

`TargetArn`

The ARN of the Amazon SNS topic.

Required: Yes

Type: String

AWS IoT TopicRule SqsAction

`Sqs` is a property of the `Actions` property that describes an action that publishes data to an SQS queue.

Syntax

JSON

```
{
  "QueueUrl": String,
  "RoleArn": String,
  "UseBase64": Boolean
}
```

YAML

```
QueueUrl: String
RoleArn: String
UseBase64: Boolean
```

Properties

`QueueUrl`

The URL of the Amazon Simple Queue Service (Amazon SQS) queue.

Required: Yes

Type: String

`RoleArn`

The ARN of the IAM role that grants access to Amazon SQS.

Required: Yes

Type: String

`UseBase64`

Specifies whether Base64 encoding should be used.

Required: No

Type: Boolean

AWS IoT TopicRule TopicRulePayload

`TopicRulePayload` is a property of the `AWS::IoT::TopicRule` resource that describes the payload of an AWS IoT rule.

Syntax

JSON

```
{
  "Actions": [ Action, ... ],
  "AwsIotSqlVersion": String,
  "Description": String,
  "RuleDisabled": Boolean,
  "Sql": String
}
```

YAML

```
Actions:
  - Action
AwsIotSqlVersion: String
Description: String
RuleDisabled: Boolean
Sql: String
```

Properties

`Actions`

The actions associated with the rule.

Required: Yes

Type: Array of `Action` (p. 1702) objects

Update requires: No interruption (p. 120)

`AwsIotSqlVersion`

The version of the SQL rules engine to use when evaluating the rule.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the rule.

Required: No

Type: String

Update requires: No interruption (p. 120)

`RuleDisabled`

Specifies whether the rule is disabled.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

`Sql`

The SQL statement that queries the topic. For more information, see Rules for AWS IoT in the *AWS IoT Developer Guide*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

AWS IoT 1-Click Resource Types Reference

This section contains reference information for all AWS IoT 1-Click resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::IoT1Click::data-type-name
```

Topics

- AWS::IoT1Click::Device (p. 1718)
- AWS::IoT1Click::Placement (p. 1720)
- AWS::IoT1Click::Project (p. 1723)

AWS::IoT1Click::Device

The `AWS::IoT1Click::Device` resource controls the enabled state of an AWS IoT 1-Click compatible device. For more information, see Device in the *AWS IoT 1-Click Devices API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::IoT1Click::Device",
  "Properties" : {
    "DeviceId" : String,
    "Enabled" : String
  }
}
```

YAML

```
Type: "AWS::IoT1Click::Device"
```

```
Properties:
  DeviceId: String
  Enabled: String
```

Properties

`DeviceId`

The unique identifier of the device.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Enabled`

A Boolean value indicating whether the device is enabled (`true`) or not (`false`).

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::IoT1Click::Device` resource to the intrinsic `Ref` function, the function returns the device ARN, such as `arn:aws:iot1click:us-west-2:123456789012:devices/G030PX0312744DWM`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The ARN of the device, such as `arn:aws:iot1click:us-west-2:123456789012:devices/G030PX0312744DWM`.

`DeviceId`

The ID of the device, such as `G030PX0312744DWM`.

`Enabled`

A Boolean value indicating whether the device is enabled (`true`) or not (`false`).

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

The following example enables a device.

JSON

```
{
  "SampleDevice": {
    "Type": "AWS::IoT1Click::Device",
    "Properties": {
      "DeviceId": "G030PX0312744DWM",
      "Enabled": true
    }
  }
}
```

YAML

```
SampleDevice:
  Type: "AWS::IoT1Click::Device"
  Properties:
    DeviceId: G030PX0312744DWM
    Enabled: True
```

- AWS IoT 1-Click Programming Model

AWS::IoT1Click::Placement

The `AWS::IoT1Click::Placement` resource creates a placement to be associated with an AWS IoT 1-Click project. For more information, see Projects, Templates, and Placements in the *AWS IoT 1-Click Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::IoT1Click::Placement",
  "Properties" : {
    "AssociatedDevices" : Json,
    "Attributes" : Json,
    "PlacementName" : String,
    "ProjectName" : String
  }
}
```

YAML

```
Type: "AWS::IoT1Click::Placement"
Properties:
  AssociatedDevices: Json
  Attributes: Json
  PlacementName: String
  ProjectName: String
```

Properties

`AssociatedDevices`

The device(s) to associate with the placement, as defined by a mapping of zero or more *key*/*value* pairs wherein the *key* is a template name and the *value* is a device ID.

Required: No

Type: Json

Update requires: Replacement (p. 121)

`Attributes`

User specified attribute(s) in the form of key/value pairs.

Required: No

Type: Json

Update requires: No interruption (p. 120)

`PlacementName`

The name of this placement.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ProjectName`

The name of the project that will contain this placement.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::IoT1Click::Placement` resource to the intrinsic `Ref` function, the function returns a string of the form `projects/`*`A`*`/placements/`*`B`* where *`A`* is the name of the project and *`B`* is the name of the placement.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`PlacementName`

The name of the placement, such as `floor17`.

`ProjectName`

The name of the project containing the placement, such as `conference-rooms`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example declares a project and placement.

JSON

```
{
    "BasicProjectWithPlacement": {
        "Type": "AWS::IoT1Click::Project",
        "Properties": {
            "ProjectName": "project-with-placements",
            "Description": "description",
            "PlacementTemplate": {
                "DefaultAttributes": {
                    "Attribute": "Value",
                    "Foo": "Bar"
                },
                "DeviceTemplates": {
                    "testButton": {
                        "DeviceType": "button",
                        "CallbackOverrides": {
                            "onClickCallback": ""
                        }
                    }
                }
            }
        }
    },

    "BasicPlacement": {
        "Type": "AWS::IoT1Click::Placement",
        "Properties": {
            "ProjectName": {
                "Ref": "BasicProjectWithPlacement"
            },
            "PlacementName": "placement"
        }
    }
}
```

YAML

```
BasicProjectWithPlacement:
  Type: "AWS::IoT1Click::Project"
  Properties:
    ProjectName: "project-with-placements"
    Description: "description"
    PlacementTemplate:
      DefaultAttributes:
        Attribute: Value
        Foo: Bar
      DeviceTemplates:
        testButton:
          DeviceType: "button"
          CallbackOverrides:
            onClickCallback: ""

BasicPlacement:
  Type: "AWS::IoT1Click::Placement"
  Properties:
    ProjectName: !Ref BasicProjectWithPlacement
```

```
    PlacementName: "placement"
```

See Also

- CreatePlacement
- Projects, Templates, and Placements
- AWS IoT 1-Click Programming Model

AWS::IoT1Click::Project

The `AWS::IoT1Click::Project` resource creates an empty project with a placement template. A project contains zero or more placements that adhere to the placement template defined in the project. For more information, see CreateProject in the *AWS IoT 1-Click Projects API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::IoT1Click::Project",
  "Properties" : {
    "Description" : String,
    "PlacementTemplate" : PlacementTemplate (p. 1725),
    "ProjectName" : String
  }
}
```

YAML

```
Type: "AWS::IoT1Click::Project"
Properties:
  Description: String
  PlacementTemplate:
    PlacementTemplate (p. 1725)
  ProjectName: String
```

Properties

`Description`

An optional description for the project.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PlacementTemplate`

The template defining the placement to be created. A placement template defines placement default attributes and device templates. You cannot add or remove device templates after the project has been created. However, you can update `callbackOverrides` for the device templates using the `UpdateProject` API.

Required: Yes

Type: PlacementTemplate (p. 1725)

Update requires: No interruption (p. 120)

`ProjectName`

The name of the project to create.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::IoT1Click::Project` resource to the intrinsic `Ref` function, the function returns the project ARN, such as `arn:aws:iot1click:us-west-2:0123456789012:projects/test-project`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The Amazon Resource Name (ARN) of the project, such as `arn:aws:iot1click:us-east-1:123456789012:projects/project-a1bzhi`.

`ProjectName`

The name of the project, such as `project-a1bzhi`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example declares an AWS IoT 1-Click project.

JSON

```
{
    "Description": "AWS IoT1Click Project test",
    "Resources": {
        "BasicProject": {
            "Type": "AWS::IoT1Click::Project",
            "Properties": {
                "ProjectName": "project",
                "Description": "description",
                "PlacementTemplate": {
                    "DefaultAttributes": {
                        "Attribute": "Value",
                        "Foo": "Bar"
                    },
                    "DeviceTemplates": {
```

```
                        "testButton": {
                            "DeviceType": "button",
                            "CallbackOverrides": {
                                "onClickCallback": ""
                            }
                        }
                    }
                }
            }
        }
    },

    "Outputs": {
        "ProjectId": {
            "Value": {
                "Ref": "BasicProject"
            }
        }
    }
}
```

YAML

```
Description: "AWS IoT1Click Project test"
Resources:
  BasicProject:
    Type: "AWS::IoT1Click::Project"
    Properties:
      ProjectName: "project"
      Description: "description"
      PlacementTemplate:
        DefaultAttributes:
          Attribute: Value
          Foo: Bar
        DeviceTemplates:
          testButton:
            DeviceType: "button"
            CallbackOverrides:
              onClickCallback: ""

Outputs:
  ProjectId:
    Value: !Ref BasicProject
```

AWS IoT 1-Click Project PlacementTemplate

In AWS CloudFormation, use the `PlacementTemplate` property type to define the template for an AWS IoT 1-Click project.

`PlacementTemplate` is a property of the AWS::IoT1Click::Project (p. 1723) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "DefaultAttributes" : Json,
  "DeviceTemplates" : Json
}
```

YAML

```
  DefaultAttributes: Json
  DeviceTemplates: Json
```

Properties

`DefaultAttributes`

The attributes (key/value pairs) to be applied to all placements using this template.

Required: No

Type: Json

Update requires: No interruption (p. 120)

`DeviceTemplates`

An object specifying the DeviceTemplate for all placements using this (PlacementTemplate) template.

Required: No

Type: Json

Update requires: Replacement (p. 121)

See Also

- Projects, Templates, and Placements
- AWS IoT 1-Click Programming Model

Amazon Kinesis Resource Types Reference

This section contains reference information for all Amazon Kinesis resources that are supported by AWS CloudFormation.

Resource type identifiers for Kinesis always take the following form:

```
AWS::Kinesis::data-type-name
```

For Kinesis Data Firehose:

```
AWS::KinesisFirehose::data-type-name
```

For Kinesis Data Analytics:

```
AWS::KinesisAnalytics::data-type-name
```

Topics

- AWS::Kinesis::Stream (p. 1727)
- AWS::KinesisFirehose::DeliveryStream (p. 1730)
- AWS::KinesisAnalytics::Application (p. 1759)
- AWS::KinesisAnalytics::ApplicationOutput (p. 1772)
- AWS::KinesisAnalytics::ApplicationReferenceDataSource (p. 1777)

AWS::Kinesis::Stream

Creates an Kinesis stream that captures and transports data records that are emitted from data sources. For information about creating streams, see CreateStream in the *Amazon Kinesis API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::Kinesis::Stream",
   "Properties" : {
      "Name" : String,
      "RetentionPeriodHours" : Integer,
      "ShardCount" : Integer,
      "StreamEncryption" : Kinesis StreamEncryption,
      "Tags" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::Kinesis::Stream
Properties:
  Name: String
  RetentionPeriodHours: Integer
  ShardCount: Integer
  StreamEncryption: Kinesis StreamEncryption
  Tags:
    - Resource Tag
```

Properties

Note
For more information about constraints and values for each property, see CreateStream in the *Amazon Kinesis API Reference* and Amazon Kinesis Data Streams Limits in the *Amazon Kinesis Developer Guide*.

`Name`

The name of the Kinesis stream. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the stream name. For more information, see Name Type (p. 2256).

Important
If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`RetentionPeriodHours`

The number of hours for the data records that are stored in shards to remain accessible. The default value is 24. For more information about the stream retention period, see Changing the Data Retention Period in the *Amazon Kinesis Developer Guide*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`ShardCount`

The number of shards that the stream uses. For greater provisioned throughput, increase the number of shards.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

`StreamEncryption`

Enables or updates server-side encryption using an AWS KMS key for a specified stream.

Required: No

Type: Kinesis StreamEncryption (p. 1729)

Update requires: No interruption (p. 120)

`Tags`

An arbitrary set of tags (key–value pairs) to associate with the Kinesis stream. For information about constraints for this property, see Tag Restrictions in the *Amazon Kinesis Developer Guide*.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When you specify an AWS::Kinesis::Stream resource as an argument to the `Ref` function, AWS CloudFormation returns the stream name (physical ID).

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for the `Arn` attribute.

`Arn`

The Amazon resource name (ARN) of the Kinesis stream, such as `arn:aws:kinesis:us-east-2:123456789012:stream/mystream`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example creates a `Stream` resource that uses three shards, sets a seven-day retention period, and specifies the KMS key for server-side encryption.

JSON

```
"MyStream": {
  "Type": "AWS::Kinesis::Stream",
  "Properties": {
    "Name": "MyKinesisStream",
    "RetentionPeriodHours" : 168,
    "ShardCount": 3,
    "StreamEncryption":
      {
        "EncryptionType": "KMS",
        "KeyId": "!Ref myKey"
      },
    "Tags": [
      {
        "Key": "Environment",
        "Value": "Production"
      }
   ]
  }
}
```

YAML

```
MyStream:
  Type: AWS::Kinesis::Stream
  Properties:
    Name: MyKinesisStream
    RetentionPeriodHours: 168
    ShardCount: 3
    StreamEncryption:
        EncryptionType: KMS
        KeyId: !Ref myKey
    Tags:
      -
        Key: Environment
        Value: Production
```

Kinesis StreamEncryption

The `StreamEncryption` property is part of the AWS::Kinesis::Stream (p. 1727) resource that enables or updates server-side encryption using an AWS KMS key for a specified stream. For more information, see StartStreamEncryption in the *Amazon Kinesis Data Streams API Reference*.

Syntax

JSON

```
{
  "EncryptionType" : String,
  "KeyId" : String
}
```

YAML

```
EncryptionType: String
KeyId: String
```

Properties

`EncryptionType`

The encryption type to use. The only valid value is `KMS`.

Required: Yes

Type: String

`KeyId`

The GUID for the customer-managed KMS key to use for encryption. This value can be a globally unique identifier, a fully specified ARN to either an alias or a key, or an alias name prefixed by "alias/". You can also use a master key owned by Kinesis Streams by specifying the alias `aws/kinesis`.

- Key ARN example: arn:aws: `kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012`
- Alias ARN example: `arn:aws:kms:us-east-1:123456789012:alias/MyAliasName`
- Globally unique key ID example: `12345678-1234-1234-1234-123456789012`
- Alias name example: `alias/MyAliasName`
- Master key owned by Kinesis Streams: `alias/aws/kinesis`

Required: Yes

Type: String

AWS::KinesisFirehose::DeliveryStream

The `AWS::KinesisFirehose::DeliveryStream` resource creates an Amazon Kinesis Data Firehose (Kinesis Data Firehose) delivery stream that delivers real-time streaming data to an Amazon Simple Storage Service (Amazon S3), Amazon Redshift, or Amazon Elasticsearch Service (Amazon ES) destination. For more information, see Creating an Amazon Kinesis Data Firehose Delivery Stream in the *Amazon Kinesis Data Firehose Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Type" : "AWS::KinesisFirehose::DeliveryStream",
  "Properties" : {
    "DeliveryStreamName" : String,
    "DeliveryStreamType" : String,

 "ElasticsearchDestinationConfiguration" : ElasticsearchDestinationConfiguration (p. 1742),
    "ExtendedS3DestinationConfiguration" : ExtendedS3DestinationConfiguration (p. 1746),
    "KinesisStreamSourceConfiguration" : KinesisStreamSourceConfiguration (p. 1748),
    "RedshiftDestinationConfiguration" : RedshiftDestinationConfiguration (p. 1752),
    "S3DestinationConfiguration" : S3DestinationConfiguration (p. 1754),
    "SplunkDestinationConfiguration" : SplunkDestinationConfiguration (p. 1755)
  }
}
```

YAML

```
Type: AWS::KinesisFirehose::DeliveryStream
Properties:
  DeliveryStreamName: String
  DeliveryStreamType: String
  ElasticsearchDestinationConfiguration:
    ElasticsearchDestinationConfiguration (p. 1742)
  ExtendedS3DestinationConfiguration:
    ExtendedS3DestinationConfiguration (p. 1746)
  KinesisStreamSourceConfiguration:
    KinesisStreamSourceConfiguration (p. 1748)
  RedshiftDestinationConfiguration:
    RedshiftDestinationConfiguration (p. 1752)
  S3DestinationConfiguration:
    S3DestinationConfiguration (p. 1754)
  SplunkDestinationConfiguration:
    SplunkDestinationConfiguration (p. 1755)
```

Properties

`DeliveryStreamName`

A name for the delivery stream.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DeliveryStreamType`

The delivery stream type. This property can be one of the following values:

- `DirectPut`: Provider applications access the delivery stream directly.
- `KinesisStreamAsSource`: The delivery stream uses a Kinesis stream as a source.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ElasticsearchDestinationConfiguration`

An Amazon ES destination for the delivery stream.

Required: Conditional. You must specify only one destination configuration.

Type: ElasticsearchDestinationConfiguration (p. 1742)

Update requires: No interruption (p. 120). If you change the delivery stream destination from an Amazon ES destination to an Amazon S3 or Amazon Redshift destination, update requires some interruptions (p. 121).

`ExtendedS3DestinationConfiguration`

An Amazon S3 destination for the delivery stream.

Required: Conditional. You must specify only one destination configuration.

Type: ExtendedS3DestinationConfiguration (p. 1746)

Update requires: No interruption (p. 120). If you change the delivery stream destination from an Amazon Redshift destination to an Amazon ES destination, update requires some interruptions (p. 121).

`KinesisStreamSourceConfiguration`

When a Kinesis stream is used as the source for the delivery stream, a KinesisStreamSourceConfiguration (p. 1748) containing the Kinesis stream ARN and the role ARN for the source stream.

Required: No

Type: KinesisStreamSourceConfiguration (p. 1748)

Update requires: No interruption (p. 120)

`RedshiftDestinationConfiguration`

An Amazon Redshift destination for the delivery stream.

Required: Conditional. You must specify only one destination configuration.

Type: RedshiftDestinationConfiguration (p. 1752)

Update requires: No interruption (p. 120). If you change the delivery stream destination from an Amazon Redshift destination to an Amazon ES destination, update requires some interruptions (p. 121).

`S3DestinationConfiguration`

An Amazon S3 destination for the delivery stream.

Required: Conditional. You must specify only one destination configuration.

Type: S3DestinationConfiguration (p. 1754)

Update requires: No interruption (p. 120). If you change the delivery stream destination from an Amazon S3 destination to an Amazon ES destination, update requires some interruptions (p. 121).

`SplunkDestinationConfiguration`

The configuration of a destination in Splunk for the delivery stream.

Required: No

Type: SplunkDestinationConfiguration (p. 1755)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the delivery stream name, such as `mystack-deliverystream-1ABCD2EF3GHIJ`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The Amazon Resource Name (ARN) of the delivery stream, such as `arn:aws:firehose:us-east-2:123456789012:deliverystream/delivery-stream-name`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

The following example creates a Kinesis Data Firehose delivery stream that delivers data to an Amazon ES destination. Kinesis Data Firehose backs up all data sent to the destination in an Amazon S3 bucket.

JSON

```
"ElasticSearchDeliveryStream": {
  "Type": "AWS::KinesisFirehose::DeliveryStream",
  "Properties": {
    "ElasticsearchDestinationConfiguration": {
      "BufferingHints": {
        "IntervalInSeconds": 60,
        "SizeInMBs": 50
      },
      "CloudWatchLoggingOptions": {

Amazon Kinesis Data Firehose DeliveryStream BufferingHints

The `BufferingHints` property type specifies how Amazon Kinesis Data Firehose (Kinesis Data Firehose) buffers incoming data before delivering it to the destination. The first buffer condition that is satisfied triggers Kinesis Data Firehose to deliver the data.

`BufferingHints` is a property of the Amazon Kinesis Data Firehose DeliveryStream ExtendedS3DestinationConfiguration (p. 1746) and Amazon Kinesis Data Firehose DeliveryStream S3DestinationConfiguration (p. 1754) property types.

Syntax

JSON

```
{
  "IntervalInSeconds" : Integer,
  "SizeInMBs" : Integer
}
```

YAML

```
IntervalInSeconds: Integer
SizeInMBs: Integer
```

Properties

`IntervalInSeconds`

The length of time, in seconds, that Kinesis Data Firehose buffers incoming data before delivering it to the destination. For valid values, see the `IntervalInSeconds` content for the BufferingHints data type in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: Integer

`SizeInMBs`

The size of the buffer, in MBs, that Kinesis Data Firehose uses for incoming data before delivering it to the destination. For valid values, see the `SizeInMBs` content for the BufferingHints data type in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: Integer

Amazon Kinesis Data Firehose DeliveryStream CloudWatchLoggingOptions

The `CloudWatchLoggingOptions` property type specifies Amazon CloudWatch Logs (CloudWatch Logs) logging options that Amazon Kinesis Data Firehose (Kinesis Data Firehose) uses for the delivery stream.

`CloudWatchLoggingOptions` is a property of the Amazon Kinesis Data Firehose DeliveryStream ElasticsearchDestinationConfiguration (p. 1742), Amazon Kinesis Data Firehose DeliveryStream ExtendedS3DestinationConfiguration (p. 1746), Amazon Kinesis Data Firehose DeliveryStream RedshiftDestinationConfiguration (p. 1752), Amazon Kinesis Data Firehose DeliveryStream SplunkDestinationConfiguration (p. 1755), and Amazon Kinesis Data Firehose DeliveryStream S3DestinationConfiguration (p. 1754) property types.

Syntax

JSON

```
{
  "Enabled" : Boolean,
  "LogGroupName" : String,
  "LogStreamName" : String
}
```

YAML

```
Enabled: Boolean
LogGroupName: String
LogStreamName: String
```

Properties

`Enabled`

Indicates whether CloudWatch Logs logging is enabled.

Required: No

Type: Boolean

`LogGroupName`

The name of the CloudWatch Logs log group that contains the log stream that Kinesis Data Firehose will use.

Required: Conditional. If you enable logging, you must specify this property.

Type: String

`LogStreamName`

The name of the CloudWatch Logs log stream that Kinesis Data Firehose uses to send logs about data delivery.

Required: Conditional. If you enable logging, you must specify this property.

Type: String

Amazon Kinesis Data Firehose DeliveryStream CopyCommand

The `CopyCommand` property type configures the Amazon Redshift `COPY` command that Amazon Kinesis Data Firehose (Kinesis Data Firehose) uses to load data into an Amazon Redshift cluster from an Amazon S3 bucket.

`CopyCommand` is a property of the Amazon Kinesis Data Firehose DeliveryStream RedshiftDestinationConfiguration (p. 1752) property type.

Syntax

JSON

```
{
  "CopyOptions" : String,
  "DataTableColumns" : String,
```

```
  "DataTableName" : String
}
```

YAML

```
CopyOptions: String
DataTableColumns: String
DataTableName: String
```

Properties

`CopyOptions`

Parameters to use with the Amazon Redshift `COPY` command. For examples, see the `CopyOptions` content for the CopyCommand data type in the *Amazon Kinesis Data Firehose API Reference*.

Required: No

Type: String

`DataTableColumns`

A comma-separated list of the column names in the table that Kinesis Data Firehose copies data to.

Required: No

Type: String

`DataTableName`

The name of the table where Kinesis Data Firehose adds the copied data.

Required: Yes

Type: String

Amazon Kinesis Data Firehose DeliveryStream ElasticsearchBufferingHints

The `ElasticsearchBufferingHints` property type specifies how Amazon Kinesis Data Firehose (Kinesis Data Firehose) buffers incoming data while delivering it to the destination. The first buffer condition that is satisfied triggers Kinesis Data Firehose to deliver the data.

`ElasticsearchBufferingHints` is the property type for the `BufferingHints` property of the Amazon Kinesis Data Firehose DeliveryStream ElasticsearchDestinationConfiguration (p. 1742) property type.

Syntax

JSON

```
{
  "IntervalInSeconds" : Integer,
  "SizeInMBs" : Integer
}
```

YAML

```
IntervalInSeconds: Integer
SizeInMBs: Integer
```

Properties

`IntervalInSeconds`

The length of time, in seconds, that Kinesis Data Firehose buffers incoming data before delivering it to the destination. For valid values, see the `IntervalInSeconds` content for the BufferingHints data type in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: Integer

`SizeInMBs`

The size of the buffer, in MBs, that Kinesis Data Firehose uses for incoming data before delivering it to the destination. For valid values, see the `SizeInMBs` content for the BufferingHints data type in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: Integer

Amazon Kinesis Data Firehose DeliveryStream ElasticsearchDestinationConfiguration

The `ElasticsearchDestinationConfiguration` property type specifies an Amazon Elasticsearch Service (Amazon ES) domain that Amazon Kinesis Data Firehose (Kinesis Data Firehose) delivers data to.

`ElasticsearchDestinationConfiguration` is a property of the AWS::KinesisFirehose::DeliveryStream (p. 1730) resource.

Syntax

JSON

```
{
  "BufferingHints" : BufferingHints (p. 1741),
  "CloudWatchLoggingOptions" : CloudWatchLoggingOptions (p. 1739),
  "DomainARN" : String,
  "IndexName" : String,
  "IndexRotationPeriod" : String,
  "ProcessingConfiguration" : ProcessingConfiguration (p. 1749),
  "RetryOptions" : RetryOptions (p. 1744),
  "RoleARN" : String,
  "S3BackupMode" : String,
  "S3Configuration" : S3Configuration (p. 1754),
  "TypeName" : String
}
```

YAML

```
BufferingHints:
  BufferingHints (p. 1741)
CloudWatchLoggingOptions:
  CloudWatchLoggingOptions (p. 1739)
DomainARN: String
IndexName: String
IndexRotationPeriod: String
ProcessingConfiguration:
  ProcessingConfiguration (p. 1749)
```

```
RetryOptions:
  RetryOptions (p. 1744)
RoleARN: String
S3BackupMode: String
S3Configuration:
  S3Configuration (p. 1754)
TypeName: String
```

Properties

`BufferingHints`

Configures how Kinesis Data Firehose buffers incoming data while delivering it to the Amazon ES domain.

Required: Yes

Type: ElasticsearchBufferingHints (p. 1741)

`CloudWatchLoggingOptions`

The Amazon CloudWatch Logs logging options for the delivery stream.

Required: No

Type: CloudWatchLoggingOptions (p. 1739)

`DomainARN`

The Amazon Resource Name (ARN) of the Amazon ES domain that Kinesis Data Firehose delivers data to.

Required: Yes

Type: String

`IndexName`

The name of the Elasticsearch index to which Kinesis Data Firehose adds data for indexing.

Required: Yes

Type: String

`IndexRotationPeriod`

The frequency of Elasticsearch index rotation. If you enable index rotation, Kinesis Data Firehose appends a portion of the UTC arrival timestamp to the specified index name, and rotates the appended timestamp accordingly. For more information, see Index Rotation for the Amazon ES Destination in the *Amazon Kinesis Data Firehose Developer Guide*.

Required: Yes

Type: String

`ProcessingConfiguration`

The data processing configuration for the Kinesis Data Firehose delivery stream.

Required: No

Type: ProcessingConfiguration (p. 1749)

`RetryOptions`

The retry behavior when Kinesis Data Firehose is unable to deliver data to Amazon ES.

Required: Yes

Type: ElasticsearchRetryOptions (p. 1744)

`RoleARN`

The ARN of the AWS Identity and Access Management (IAM) role that grants Kinesis Data Firehose access to your Amazon S3 bucket, AWS KMS (if you enable data encryption), and Amazon CloudWatch Logs (if you enable logging).

For more information, see Grant Kinesis Data Firehose Access to an Amazon Elasticsearch Service Destination in the *Amazon Kinesis Data Firehose Developer Guide*.

Required: Yes

Type: String

`S3BackupMode`

The condition under which Kinesis Data Firehose delivers data to Amazon Simple Storage Service (Amazon S3). You can send Amazon S3 all documents (all data) or only the documents that Kinesis Data Firehose could not deliver to the Amazon ES destination. For more information and valid values, see the `S3BackupMode` content for the ElasticsearchDestinationConfiguration data type in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: String

`S3Configuration`

The S3 bucket where Kinesis Data Firehose backs up incoming data.

Required: Yes

Type: S3DestinationConfiguration (p. 1754)

`TypeName`

The Elasticsearch type name that Amazon ES adds to documents when indexing data.

Required: Yes

Type: String

Amazon Kinesis Data Firehose DeliveryStream ElasticsearchRetryOptions

The `ElasticsearchRetryOptions` property type configures the retry behavior for when Amazon Kinesis Data Firehose (Kinesis Data Firehose) can't deliver data to Amazon Elasticsearch Service (Amazon ES).

`RetryOptions` is a property of the Amazon Kinesis Data Firehose DeliveryStream ElasticsearchDestinationConfiguration (p. 1742) property type.

Syntax

JSON

```
{
  "DurationInSeconds" : Integer
}
```

YAML

```
DurationInSeconds: Integer
```

Properties

`DurationInSeconds`

After an initial failure to deliver to Amazon ES, the total amount of time during which Kinesis Data Firehose re-attempts delivery (including the first attempt). If Kinesis Data Firehose can't deliver the data within the specified time, it writes the data to the backup S3 bucket. For valid values, see the `DurationInSeconds` content for the ElasticsearchRetryOptions data type in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: Integer

Amazon Kinesis Data Firehose DeliveryStream EncryptionConfiguration

The `EncryptionConfiguration` property type specifies the encryption settings that Amazon Kinesis Data Firehose (Kinesis Data Firehose) uses when delivering data to Amazon Simple Storage Service (Amazon S3).

`EncryptionConfiguration` is a property of the Amazon Kinesis Data Firehose DeliveryStream S3DestinationConfiguration (p. 1754) property type.

Syntax

JSON

```
{
  "KMSEncryptionConfig" : KMSEncryptionConfig (p. 1749),
  "NoEncryptionConfig" : String
}
```

YAML

```
KMSEncryptionConfig:
  KMSEncryptionConfig (p. 1749)
NoEncryptionConfig: String
```

Properties

`KMSEncryptionConfig`

The AWS Key Management Service (AWS KMS) encryption key that Amazon S3 uses to encrypt your data.

Required: No

Type: Amazon Kinesis Data Firehose DeliveryStream KMSEncryptionConfig (p. 1749)

`NoEncryptionConfig`

Disables encryption. For valid values, see the `NoEncryptionConfig` content for the EncryptionConfiguration data type in the *Amazon Kinesis Data Firehose API Reference*.

Required: No

Type: String

Amazon Kinesis Data Firehose DeliveryStream ExtendedS3DestinationConfiguration

The `ExtendedS3DestinationConfiguration` property type configures an Amazon S3 destination for an Amazon Kinesis Data Firehose delivery stream. `ExtendedS3DestinationConfiguration` is a property of the AWS::KinesisFirehose::DeliveryStream (p. 1730) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "BucketARN" : String,
  "BufferingHints" : BufferingHints (p. 1739),
  "CloudWatchLoggingOptions" : CloudWatchLoggingOptions (p. 1739),
  "CompressionFormat" : String,
  "EncryptionConfiguration" : EncryptionConfiguration (p. 1745),
  "Prefix" : String,
  "ProcessingConfiguration" : ProcessingConfiguration (p. 1749),
  "RoleARN" : String,
  "S3BackupConfiguration" : S3DestinationConfiguration (p. 1754),
  "S3BackupMode" : String
}
```

YAML

```
  BucketARN: String
  BufferingHints:
    BufferingHints (p. 1739)
  CloudWatchLoggingOptions:
    CloudWatchLoggingOptions (p. 1739)
  CompressionFormat: String
  EncryptionConfiguration:
    EncryptionConfiguration (p. 1745)
  Prefix: String
  ProcessingConfiguration:
    ProcessingConfiguration (p. 1749)
  RoleARN: String
  S3BackupConfiguration:
    S3DestinationConfiguration (p. 1754)
  S3BackupMode: String
```

Properties

`BucketARN`

The Amazon Resource Name (ARN) of the Amazon S3 bucket. For constraints, see ExtendedS3DestinationConfiguration in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`BufferingHints`

The buffering option.

Required: Yes

Type: BufferingHints (p. 1739)

Update requires: No interruption (p. 120)

`CloudWatchLoggingOptions`

The CloudWatch logging options for the Kinesis Data Firehose delivery stream.

Required: No

Type: CloudWatchLoggingOptions (p. 1739)

Update requires: No interruption (p. 120)

`CompressionFormat`

The compression format for the Kinesis Data Firehose delivery stream. The default value is `UNCOMPRESSED`. For valid values, see ExtendedS3DestinationConfiguration in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`EncryptionConfiguration`

The encryption configuration for the Kinesis Data Firehose delivery stream. The default value is `NoEncryption`.

Required: No

Type: EncryptionConfiguration (p. 1745)

Update requires: No interruption (p. 120)

`Prefix`

The `YYYY/MM/DD/HH` time format prefix is automatically used for delivered Amazon S3 files. For more information, see ExtendedS3DestinationConfiguration in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ProcessingConfiguration`

The data processing configuration for the Kinesis Data Firehose delivery stream.

Required: No

Type: ProcessingConfiguration (p. 1749)

Update requires: No interruption (p. 120)

`RoleARN`

The ARN of the AWS credentials. For constraints, see ExtendedS3DestinationConfiguration in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`S3BackupConfiguration`

The configuration for backup in Amazon S3.

Required: No

Type: S3DestinationConfiguration (p. 1754)

Update requires: No interruption (p. 120)

`S3BackupMode`

The Amazon S3 backup mode. For valid values, see ExtendedS3DestinationConfiguration in the *Amazon Kinesis Data Firehose API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Firehose DeliveryStream KinesisStreamSourceConfiguration

The `KinesisStreamSourceConfiguration` property type specifies the stream and role Amazon Resource Names (ARNs) for a Kinesis stream used as the source for a delivery stream.

`KinesisStreamSourceConfiguration` is a property of the AWS::KinesisFirehose::DeliveryStream (p. 1730) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "KinesisStreamARN" : String
  "RoleARN" : String
}
```

YAML

```
KinesisStreamARN: String
RoleARN: String
```

Properties

`KinesisStreamARN`

The Amazon Resource Name (ARN) of the source Kinesis stream.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoleARN`

The Amazon Resource Name (ARN) of the role that provides access to the source Kinesis stream.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Firehose DeliveryStream KMSEncryptionConfig

The `KMSEncryptionConfig` property type specifies the AWS Key Management Service (AWS KMS) encryption key that Amazon Simple Storage Service (Amazon S3) uses to encrypt data delivered by the Amazon Kinesis Data Firehose (Kinesis Data Firehose) stream.

`KMSEncryptionConfig` is a property of the Amazon Kinesis Data Firehose DeliveryStream KMSEncryptionConfig (p. 1749) property type.

Syntax

JSON

```
{
  "AWSKMSKeyARN" : String
}
```

YAML

```
AWSKMSKeyARN: String
```

Properties

`AWSKMSKeyARN`

The Amazon Resource Name (ARN) of the AWS KMS encryption key that Amazon S3 uses to encrypt data delivered by the Kinesis Data Firehose stream. The key must belong to the same region as the destination S3 bucket.

Required: Yes

Type: String

Amazon Kinesis Data Firehose DeliveryStream ProcessingConfiguration

The `ProcessingConfiguration` property configures data processing for an Amazon Kinesis Data Firehose delivery stream.

`ProcessingConfiguration` is a property of the ElasticsearchDestinationConfiguration (p. 1742), ExtendedS3DestinationConfiguration (p. 1746), RedshiftDestinationConfiguration (p. 1752), and SplunkDestinationConfiguration (p. 1755) property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Enabled" : Boolean,
  "Processors" : [ Processor (p. 1750), ... ]
}
```

YAML

```
  Enabled: Boolean
  Processors:
    - Processor (p. 1750)
```

Properties

`Enabled`

Indicates whether data processing is enabled (`true`) or disabled (`false`).

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Processors`

The data processors.

Required: Yes

Type: List of Processor (p. 1750)

Update requires: No interruption (p. 120)

Amazon Kinesis Data Firehose DeliveryStream Processor

The `Processor` property specifies a data processor for an Amazon Kinesis Data Firehose delivery stream. `Processor` is a property of the Amazon Kinesis Data Firehose DeliveryStream ProcessingConfiguration (p. 1749) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Parameters" : [ ProcessorParameter (p. 1751), ... ],
  "Type" : String
}
```

YAML

```
  Parameters:
    - ProcessorParameter (p. 1751)
  Type: String
```

Properties

`Parameters`

The processor parameters.

Required: Yes

Type: List of Amazon Kinesis Data Firehose DeliveryStream ProcessorParameter (p. 1751)

Update requires: No interruption (p. 120)

`Type`

The type of processor. Valid values: `Lambda`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Firehose DeliveryStream ProcessorParameter

The `ProcessorParameter` property specifies a processor parameter in a data processor for an Amazon Kinesis Data Firehose delivery stream.

`ProcessorParameter` is a property of the Amazon Kinesis Data Firehose DeliveryStream Processor (p. 1750) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ParameterName" : String,
  "ParameterValue" : String
}
```

YAML

```
  ParameterName: String
  ParameterValue: String
```

Properties

For more information about each property, including constraints and valid values, see ProcessorParameter in the *Amazon Kinesis Data Firehose API Reference*.

`ParameterName`

The name of the parameter.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ParameterValue`

The parameter value.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Firehose DeliveryStream RedshiftDestinationConfiguration

The `RedshiftDestinationConfiguration` property type specifies an Amazon Redshift cluster to which Amazon Kinesis Data Firehose (Kinesis Data Firehose) delivers data.

`RedshiftDestinationConfiguration` is a property of the AWS::KinesisFirehose::DeliveryStream (p. 1730) resource.

Syntax

JSON

```
{
  "CloudWatchLoggingOptions" : CloudWatchLoggingOptions (p. 1739),
  "ClusterJDBCURL" : String,
  "CopyCommand" : CopyCommand (p. 1740),
  "Password" : String,
  "ProcessingConfiguration" : ProcessingConfiguration (p. 1749),
  "RoleARN" : String,
  "S3Configuration" : S3Configuration (p. 1754),
  "Username" : String
}
```

YAML

```
CloudWatchLoggingOptions:
  CloudWatchLoggingOptions (p. 1739)
ClusterJDBCURL: String
CopyCommand:
  CopyCommand (p. 1740)
Password: String
ProcessingConfiguration:
  ProcessingConfiguration (p. 1749)
RoleARN: String
S3Configuration:
```

```
  S3Configuration (p. 1754)
Username: String
```

Properties

`CloudWatchLoggingOptions`

The Amazon CloudWatch Logs logging options for the delivery stream.

Required: No

Type: CloudWatchLoggingOptions (p. 1739)

`ClusterJDBCURL`

The connection string that Kinesis Data Firehose uses to connect to the Amazon Redshift cluster.

Required: Yes

Type: String

`CopyCommand`

Configures the Amazon Redshift `COPY` command that Kinesis Data Firehose uses to load data into the cluster from the Amazon S3 bucket.

Required: Yes

Type: CopyCommand (p. 1740)

`Password`

The password for the Amazon Redshift user that you specified in the `Username` property.

Required: Yes

Type: String

`ProcessingConfiguration`

The data processing configuration for the Kinesis Data Firehose delivery stream.

Required: No

Type: ProcessingConfiguration (p. 1749)

`RoleARN`

The ARN of the AWS Identity and Access Management (IAM) role that grants Kinesis Data Firehose access to your Amazon S3 bucket and AWS KMS (if you enable data encryption).

For more information, see Grant Kinesis Data Firehose Access to an Amazon Redshift Destination in the *Amazon Kinesis Data Firehose Developer Guide*.

Required: Yes

Type: String

`S3Configuration`

The S3 bucket where Kinesis Data Firehose first delivers data. After the data is in the bucket, Kinesis Data Firehose uses the `COPY` command to load the data into the Amazon Redshift cluster. For the Amazon S3 bucket's compression format, don't specify `SNAPPY` or `ZIP` because the Amazon Redshift `COPY` command doesn't support them.

Required: Yes

Type: S3DestinationConfiguration (p. 1754)

`Username`

The Amazon Redshift user that has permission to access the Amazon Redshift cluster. This user must have `INSERT` privileges for copying data from the Amazon S3 bucket to the cluster.

Required: Yes

Type: String

Amazon Kinesis Data Firehose DeliveryStream S3DestinationConfiguration

The `S3DestinationConfiguration` property type specifies an Amazon Simple Storage Service (Amazon S3) destination to which Amazon Kinesis Data Firehose (Kinesis Data Firehose) delivers data.

`S3DestinationConfiguration` is a property of the AWS::KinesisFirehose::DeliveryStream (p. 1730) resource and the Amazon Kinesis Data Firehose DeliveryStream ElasticsearchDestinationConfiguration (p. 1742), Amazon Kinesis Data Firehose DeliveryStream RedshiftDestinationConfiguration (p. 1752), and Amazon Kinesis Data Firehose DeliveryStream SplunkDestinationConfiguration (p. 1755) property types.

Syntax

JSON

```
{
  "BucketARN" : String,
  "BufferingHints" : BufferingHints (p. 1739),
  "CloudWatchLoggingOptions" : CloudWatchLoggingOptions (p. 1739),
  "CompressionFormat" : String,
  "EncryptionConfiguration" : EncryptionConfiguration (p. 1745),
  "Prefix" : String,
  "RoleARN" : String
}
```

YAML

```
BucketARN: String
BufferingHints:
  BufferingHints (p. 1739)
CloudWatchLoggingOptions:
  CloudWatchLoggingOptions (p. 1739)
CompressionFormat: String
EncryptionConfiguration:
  EncryptionConfiguration (p. 1745)
Prefix: String
RoleARN: String
```

Properties

`BucketARN`

The Amazon Resource Name (ARN) of the Amazon S3 bucket to send data to.

Required: Yes

Type: String

`BufferingHints`

Configures how Kinesis Data Firehose buffers incoming data while delivering it to the Amazon S3 bucket.

Required: Yes

Type: BufferingHints (p. 1739)

`CloudWatchLoggingOptions`

The Amazon CloudWatch Logs logging options for the delivery stream.

Required: No

Type: Amazon Kinesis Data Firehose DeliveryStream CloudWatchLoggingOptions (p. 1739)

`CompressionFormat`

The type of compression that Kinesis Data Firehose uses to compress the data that it delivers to the Amazon S3 bucket. For valid values, see the `CompressionFormat` content for the S3DestinationConfiguration data type in the *Amazon Kinesis Data Firehose API Reference*.

Required: Yes

Type: String

`EncryptionConfiguration`

Configures Amazon Simple Storage Service (Amazon S3) server-side encryption. Kinesis Data Firehose uses AWS Key Management Service (AWS KMS) to encrypt the data that it delivers to your Amazon S3 bucket.

Required: No

Type: Amazon Kinesis Data Firehose DeliveryStream EncryptionConfiguration (p. 1745)

`Prefix`

A prefix that Kinesis Data Firehose adds to the files that it delivers to the Amazon S3 bucket. The prefix helps you identify the files that Kinesis Data Firehose delivered.

Required: No

Type: String

`RoleARN`

The ARN of an AWS Identity and Access Management (IAM) role that grants Kinesis Data Firehose access to your Amazon S3 bucket and AWS KMS (if you enable data encryption).

For more information, see Grant Kinesis Data Firehose Access to an Amazon S3 Destination in the *Amazon Kinesis Data Firehose Developer Guide*.

Required: Yes

Type: String

Amazon Kinesis Data Firehose DeliveryStream SplunkDestinationConfiguration

The `SplunkDestinationConfiguration` property type specifies the configuration of a destination in Splunk for a Kinesis Data Firehose delivery stream.

`SplunkDestinationConfiguration` is a property of the AWS::KinesisFirehose::DeliveryStream (p. 1730) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "CloudWatchLoggingOptions" : CloudWatchLoggingOptions (p. 1739),
  "HECAcknowledgmentTimeoutInSeconds" : Integer,
  "HECEndpoint" : String,
  "HECEndpointType" : String,
  "HECToken" : String,
  "ProcessingConfiguration" : ProcessingConfiguration (p. 1749),
  "RetryOptions" : RetryOptions (p. 1758),
  "S3BackupMode" : String,
  "S3Configuration" : S3Configuration (p. 1754)
}
```

YAML

```
CloudWatchLoggingOptions:
  CloudWatchLoggingOptions (p. 1739)
HECAcknowledgmentTimeoutInSeconds: Integer
HECEndpoint: String
HECEndpointType: String
HECToken: String
ProcessingConfiguration:
  ProcessingConfiguration (p. 1749)
RetryOptions:
  RetryOptions (p. 1758)
S3BackupMode: String
S3Configuration:
  S3Configuration (p. 1754)
```

Properties

`CloudWatchLoggingOptions`

The CloudWatch logging options for your delivery stream.

Required: No

Type: CloudWatchLoggingOptions (p. 1739)

Update requires: No interruption (p. 120)

`HECAcknowledgmentTimeoutInSeconds`

The amount of time that Kinesis Data Firehose waits to receive an acknowledgment from Splunk after it sends it data. At the end of the timeout period, Kinesis Data Firehose either tries to send the data again or considers it an error, based on your retry settings.

Valid Range: Minimum value of 180. Maximum value of 600.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`HECEndpoint`

The HTTP Event Collector (HEC) endpoint to which Kinesis Data Firehose sends your data.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`HECEndpointType`

This type can be either `Raw` or `Event`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`HECToken`

A GUID that you obtain from your Splunk cluster when you create a new HEC endpoint.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ProcessingConfiguration`

The data processing configuration.

Required: No

Type: ProcessingConfiguration (p. 1749)

Update requires: No interruption (p. 120)

`RetryOptions`

The retry behavior in case Kinesis Data Firehose is unable to deliver data to Splunk, or if it doesn't receive an acknowledgment of receipt from Splunk.

Required: No

Type: SplunkRetryOptions (p. 1758)

Update requires: No interruption (p. 120)

`S3BackupMode`

Defines how documents should be delivered to Amazon S3. When set to `FailedEventsOnly`, Kinesis Data Firehose writes any data that could not be indexed to the configured Amazon S3 destination. When set to `AllEvents`, Kinesis Data Firehose delivers all incoming records to Amazon S3, and also writes failed documents to Amazon S3. Default value is `FailedEventsOnly`.

Valid values include `FailedEventsOnly` and `AllEvents`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`S3Configuration`

The configuration for the backup Amazon S3 location.

Required: Yes

Type: S3DestinationConfiguration (p. 1754)

Update requires: No interruption (p. 120)

See Also

- SplunkDestinationConfiguration in the *Amazon Kinesis Data Firehose API Reference*

Amazon Kinesis Data Firehose DeliveryStream SplunkRetryOptions

The `SplunkRetryOptions` property type specifies retry behavior in case Kinesis Data Firehose is unable to deliver documents to Splunk or if it doesn't receive an acknowledgment from Splunk.

`SplunkRetryOptions` is a property of the Amazon Kinesis Data Firehose DeliveryStream SplunkDestinationConfiguration (p. 1755) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "DurationInSeconds" : Integer
}
```

YAML

```
DurationInSeconds: Integer
```

Properties

`DurationInSeconds`

The total amount of time that Kinesis Data Firehose spends on retries. This duration starts after the initial attempt to send data to Splunk fails and doesn't include the periods during which Kinesis Data Firehose waits for acknowledgment from Splunk after each attempt.

Valid Range: Minimum value of 0. Maximum value of 7200.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

- SplunkRetryOptions in the *Amazon Kinesis Data Firehose API Reference*

AWS::KinesisAnalytics::Application

The `AWS::KinesisAnalytics::Application` resource creates an Amazon Kinesis Data Analytics application. For more information, see the *Amazon Kinesis Data Analytics Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::KinesisAnalytics::Application",
  "Properties" : {
    "ApplicationName" : String,
    "ApplicationDescription" : String,
    "ApplicationCode" : String,
    "Inputs" : [ Input (p. 1762), ... ]
  }
}
```

YAML

```
Type: AWS::KinesisAnalytics::Application
Properties:
  ApplicationName: String
  ApplicationDescription: String
  ApplicationCode: String
  Inputs:
    - Input (p. 1762)
```

Properties

`ApplicationName`

The name of your Amazon Kinesis Data Analytics application.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ApplicationDescription`

The summary description of the application.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ApplicationCode`

One or more SQL statements that read input data, transform it, and generate output.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Inputs`

Use this parameter to configure the application input.

Required: Yes

Type: List of Input (p. 1762)

Update requires: No interruption (p. 120)

Example

Creating an Amazon Kinesis Data Analytics Application

The following example demonstrates how to create and configure a Kinesis Data Analytics application.

YAML

```
---
Description: "Sample KinesisAnalytics via CloudFormation"
Resources:
  BasicApplication:
    Type: AWS::KinesisAnalytics::Application
    Properties:
      ApplicationName: "sampleApplication"
      ApplicationDescription: "SampleApp"
      ApplicationCode: "Example Application Code"
      Inputs:
        - NamePrefix: "exampleNamePrefix"
          InputSchema:
            RecordColumns:
             - Name: "example"
               SqlType: "VARCHAR(16)"
               Mapping: "$.example"
            RecordFormat:
              RecordFormatType: "JSON"
              MappingParameters:
                JSONMappingParameters:
                  RecordRowPath: "$"
          KinesisStreamsInput:
            ResourceARN: !GetAtt InputKinesisStream.Arn
            RoleARN: !GetAtt KinesisAnalyticsRole.Arn
  InputKinesisStream:
    Type: AWS::Kinesis::Stream
    Properties:
      ShardCount: 1
  KinesisAnalyticsRole:
    Type: AWS::IAM::Role
    Properties:
      AssumeRolePolicyDocument:
        Version: "2012-10-17"
        Statement:
          - Effect: Allow
            Principal:
              Service: kinesisanalytics.amazonaws.com
            Action: "sts:AssumeRole"
      Path: "/"
      Policies:
        - PolicyName: Open
          PolicyDocument:
            Version: "2012-10-17"
```

```
            Statement:
              - Effect: Allow
                Action: "*"
                Resource: "*"
  BasicApplicationOutputs:
    Type: AWS::KinesisAnalytics::ApplicationOutput
    DependsOn: BasicApplication
    Properties:
      ApplicationName: !Ref BasicApplication
      Output:
        Name: "exampleOutput"
        DestinationSchema:
          RecordFormatType: "CSV"
        KinesisStreamsOutput:
          ResourceARN: !GetAtt OutputKinesisStream.Arn
          RoleARN: !GetAtt KinesisAnalyticsRole.Arn
  OutputKinesisStream:
    Type: AWS::Kinesis::Stream
    Properties:
      ShardCount: 1
  ApplicationReferenceDataSource:
    Type: AWS::KinesisAnalytics::ApplicationReferenceDataSource
    DependsOn: BasicApplicationOutputs
    Properties:
      ApplicationName: !Ref BasicApplication
      ReferenceDataSource:
        TableName: "exampleTable"
        ReferenceSchema:
          RecordColumns:
            - Name: "example"
              SqlType: "VARCHAR(16)"
              Mapping: "$.example"
          RecordFormat:
            RecordFormatType: "JSON"
            MappingParameters:
              JSONMappingParameters:
                RecordRowPath: "$"
        S3ReferenceDataSource:
          BucketARN: !GetAtt S3Bucket.Arn
          FileKey: 'fakeKey'
          ReferenceRoleARN: !GetAtt KinesisAnalyticsRole.Arn
  S3Bucket:
    Type: AWS::S3::Bucket
Outputs:
  ApplicationPhysicalResourceId:
    Value: !Ref BasicApplication
```

Amazon Kinesis Data Analytics Application CSVMappingParameters

The `CSVMappingParameters` property type specifies additional mapping information when the record format uses delimiters, such as CSV.

`CSVMappingParameters` is a property of the MappingParameters (p. 1769) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "RecordColumnDelimiter" : String,
  "RecordRowDelimiter" : String
```

```
}
```

YAML

```
  RecordColumnDelimiter: String
  RecordRowDelimiter: String
```

Properties

`RecordColumnDelimiter`

The column delimiter. For example, in a CSV format, a comma (",") is the typical column delimiter.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RecordRowDelimiter`

The row delimiter. For example, in a CSV format, "\n" is the typical row delimiter.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application Input

When you configure the application input, you specify the streaming source, the in-application stream name that is created, and the mapping between the two.

`Input` is a property of the AWS::KinesisAnalytics::Application (p. 1759) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "NamePrefix" : String,
  "InputParallelism" : InputParallelism (p. 1765),
  "InputSchema" : InputSchema (p. 1766),
  "KinesisFirehoseInput" : KinesisFirehoseInput (p. 1767),
  "KinesisStreamsInput" : KinesisStreamsInput (p. 1768),
  "InputProcessingConfiguration :  InputProcessingConfiguration (p. 1765)
}
```

YAML

```
  NamePrefix: String
  InputParallelism:
```

```
    InputParallelism (p. 1765)
  InputSchema:
    InputSchema (p. 1766)
  KinesisFirehoseInput:
    KinesisFirehoseInput (p. 1767)
  KinesisStreamsInput:
    KinesisStreamsInput (p. 1768)
  InputProcessingConfiguration:
    InputProcessingConfiguration (p. 1765)
```

Properties

`NamePrefix`

The name prefix to use when creating the in-application streams.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`InputParallelism`

Describes the number of in-application streams to create.

Required: No

Type: InputParallelism (p. 1765)

Update requires: No interruption (p. 120)

`InputSchema`

Describes the format of the data in the streaming source, and how each data element maps to corresponding columns in the in-application stream that is being created.

Required: Yes

Type: InputSchema (p. 1766)

Update requires: No interruption (p. 120)

`KinesisFirehoseInput`

If the streaming source is an Amazon Kinesis Data Firehose delivery stream, identifies the delivery stream's Amazon Resource Name (ARN) and an IAM role that enables Kinesis Data Analytics to access the stream on your behalf.

Required: No

Type: KinesisFirehoseInput (p. 1767)

Update requires: No interruption (p. 120)

`KinesisStreamsInput`

If the streaming source is an Amazon Kinesis stream, identifies the stream's ARN and an IAM role that enables Kinesis Data Analytics to access the stream on your behalf.

Required: No

Type: KinesisStreamsInput (p. 1768)

Update requires: No interruption (p. 120)

`InputProcessingConfiguration`

The input processing configuration for the input. An input processor transforms records as they are received from the stream, before the application's SQL code executes. Currently, the only input processing configuration available is `InputLambdaProcessor`.

Required: No

Type: InputProcessingConfiguration (p. 1765)

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application InputLambdaProcessor

The `InputLambdaProcessor` property type specifies the Amazon Resource Name (ARN) of a Lambda function for preprocessing records in a stream before the SQL code for an Amazon Kinesis Data Analytics application executes.

`InputLambdaProcessor` is a property of the Input (p. 1762) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ResourceARN" : String,
  "RoleARN" : String
}
```

YAML

```
  ResourceARN: String
  RoleARN: String
```

Properties

`ResourceARN`

The ARN of the AWS Lambda function that operates on records in the stream.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoleARN`

The ARN of the IAM role that is used to access the AWS Lambda function.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application InputParallelism

The `InputParallelism` property type specifies the number of in-application streams to create for a given streaming source in an Amazon Kinesis Data Analytics application.

`InputParallelism` is a property of the Input (p. 1762) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Count" : Integer
}
```

YAML

```
  Count: Integer
```

Properties

`Count`

The number of in-application streams to create.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application InputProcessingConfiguration

The `InputProcessingConfiguration` property type specifies a processing configuration for a Input (p. 1762) for an Amazon Kinesis Data Analytics application.

`InputProcessingConfiguration` is a property of the Input (p. 1762) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "InputLambdaProcessor" : InputLambdaProcessor (p. 1764)
}
```

YAML

```
  InputLambdaProcessor: InputLambdaProcessor (p. 1764)
```

Properties

`InputLambdaProcessor`

The InputLambdaProcessor that is used to preprocess the records in the stream before they are processed by your application code.

Required: No

Type: InputLambdaProcessor (p. 1764)

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application InputSchema

The `InputSchema` property type describes the format of the data in the streaming source, and how each data element maps to corresponding columns that are created in the in-application stream in an Amazon Kinesis Data Analytics application.

`InputSchema` is a property of the Input (p. 1762) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "RecordColumns" : [ RecordColumn (p. 1770), ... ],
  "RecordEncoding" : String,
  "RecordFormat" : RecordFormat (p. 1771)
}
```

YAML

```
  RecordColumns:
    - RecordColumn (p. 1770)
  RecordEncoding: String
  RecordFormat:
    RecordFormat (p. 1771)
```

Properties

`RecordColumns`

A list of `RecordColumn` objects.

Required: Yes

Type: List of RecordColumn (p. 1770)

Update requires: No interruption (p. 120)

`RecordEncoding`

Specifies the encoding of the records in the streaming source; for example, `UTF-8`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`RecordFormat`

Specifies the format of the records on the streaming source.

Required: Yes

Type: RecordFormat (p. 1771)

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application JSONMappingParameters

The `JSONMappingParameters` property type specifies additional mapping information when JSON is the record format on the streaming source.

`JSONMappingParameters` is a property of the MappingParameters (p. 1769) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "RecordRowPath" : String
}
```

YAML

```
  RecordRowPath: String
```

Properties

`RecordRowPath`

The path to the top-level parent that contains the records (e.g., "$".)

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application KinesisFirehoseInput

The `KinesisFirehoseInput` property type identifies an Amazon Kinesis Data Firehose delivery stream as the streaming source for an Amazon Kinesis Data Analytics application.

`KinesisFirehoseInput` is a property of the Input (p. 1762) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ResourceARN" : String,
  "RoleARN" : String
}
```

YAML

```
  ResourceARN: String
  RoleARN: String
```

Properties

`ResourceARN`

The Amazon Resource Name (ARN) of the input Kinesis Data Firehose delivery stream.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoleARN`

The ARN of the IAM role that Kinesis Data Analytics can assume to access the stream on your behalf.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application KinesisStreamsInput

The `KinesisStreamsInput` property type specifies an Amazon Kinesis stream as the streaming source for an Amazon Kinesis Data Analytics application.

`KinesisStreamsInput` is a property of the Input (p. 1762) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ResourceARN" : String,
  "RoleARN" : String
}
```

YAML

```
  ResourceARN: String
```

```
  RoleARN: String
```

Properties

`ResourceARN`

The Amazon Resource Name (ARN) of the input Amazon Kinesis stream to read.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoleARN`

The ARN of the IAM role that Kinesis Data Analytics can assume to access the stream on your behalf.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application MappingParameters

When configuring application input at the time of creating or updating an application, provides additional mapping information specific to the record format (such as JSON, CSV, or record fields delimited by some delimiter) on the streaming source.

`MappingParameters` is a property of the RecordFormat (p. 1771) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "CSVMappingParameters" : CSVMappingParameters (p. 1761),
  "JSONMappingParameters" : JSONMappingParameters (p. 1767)
}
```

YAML

```
  CSVMappingParameters:
    CSVMappingParameters (p. 1761)
  JSONMappingParameters:
    JSONMappingParameters (p. 1767)
```

Properties

`CSVMappingParameters`

Provides additional mapping information when the record format uses delimiters (for example, CSV).

Required: No

Type: CSVMappingParameters (p. 1761)

Update requires: No interruption (p. 120)

`JSONMappingParameters`

Provides additional mapping information when JSON is the record format on the streaming source.

Required: No

Type: JSONMappingParameters (p. 1767)

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application RecordColumn

The `RecordColumn` property type specifies the mapping of each data element in the streaming source to the corresponding column in the in-application stream in an Amazon Kinesis Data Analytics application.

`RecordColumn` is a property of the InputSchema (p. 1766) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Mapping" : String,
  "Name" : String,
  "SqlType" : String
}
```

YAML

```
  Mapping: String
  Name: String
  SqlType: String
```

Properties

`Mapping`

Reference to the data element in the streaming input of the reference data source.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the column created in the in-application input stream or reference table.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`SqlType`

The type of column created in the in-application input stream or reference table.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics Application RecordFormat

The `RecordFormat` property type describes the record format and relevant mapping information that should be applied to schematize the records on the stream.

`RecordFormat` is a property of the AWS::KinesisAnalytics::Application (p. 1759) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "MappingParameters" : MappingParameters (p. 1769),
  "RecordFormatType" : String
}
```

YAML

```
  MappingParameters:
    MappingParameters (p. 1769)
  RecordFormatType: String
```

Properties

`MappingParameters`

When configuring application input at the time of creating or updating an application, provides additional mapping information specific to the record format (such as JSON, CSV, or record fields delimited by some delimiter) on the streaming source.

Required: No

Type: MappingParameters (p. 1769)

Update requires: No interruption (p. 120)

`RecordFormatType`

The type of record format (e.g `CSV` or `JSON`.)

Required: Yes

Type: String

Update requires: No interruption (p. 120)

AWS::KinesisAnalytics::ApplicationOutput

The `AWS::KinesisAnalytics::ApplicationOutput` resource adds an external destination to your Amazon Kinesis Data Analytics application. For more information, see AddApplicationOutput in the *Amazon Kinesis Data Analytics Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::KinesisAnalytics::ApplicationOutput",
  "Properties" : {
    "ApplicationName" : String,
    "Output" : Output (p. 1776)
  }
}
```

YAML

```
Type: AWS::KinesisAnalytics::ApplicationOutput
Properties:
  ApplicationName: String
  Output:
    Output (p. 1776)
```

Properties

`ApplicationName`

The name of the application to which you want to add the output configuration.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Output`

An array of objects, each describing one output configuration.

Required: Yes

Type: Output (p. 1776)

Update requires: No interruption (p. 120)

Examples

Adding an ApplicationOutput Resource

The following example adds an `ApplicationOutput` resource to an Amazon Kinesis Data Analytics application.

YAML

```
Type: AWS::KinesisAnalytics::ApplicationOutput
    Properties:
      ApplicationName: !Ref BasicApplication
      Output:
        Name: "exampleOutput"
        DestinationSchema:
          RecordFormatType: "CSV"
        KinesisStreamsOutput:
          ResourceARN: !GetAtt OutputKinesisStream.Arn
          RoleARN: !GetAtt KinesisAnalyticsRole.Arn
```

Amazon Kinesis Data Analytics ApplicationOutput DestinationSchema

The `DestinationSchema` property describes the data format when records are written to the destination.

`DestinationSchema` is a property of the Output (p. 1776) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "RecordFormatType" : String
}
```

YAML

```
  RecordFormatType: String
```

Properties

`RecordFormatType`

Specifies the format of the records on the output stream.

Required: No

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationOutput KinesisFirehoseOutput

The `KinesisFirehoseOutput` property type specifies an Amazon Kinesis Data Firehose delivery stream as the destination when you are configuring application output.

`KinesisFirehoseOutput` is a property of the Output (p. 1776) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ResourceARN" : String,
  "RoleARN" : String
}
```

YAML

```
  ResourceARN: String
  RoleARN: String
```

Properties

`ResourceARN`

The Amazon Resource Name (ARN) of the destination Amazon Kinesis Data Firehose delivery stream to write to.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoleARN`

The ARN of the IAM role that Amazon Kinesis Data Analytics can assume to write to the destination stream on your behalf.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationOutput KinesisStreamsOutput

The `KinesisStreamsOutput` property type specifies an Amazon Kinesis stream as the destination when you are configuring application output.

`KinesisStreamsOutput` is a property of the Output (p. 1776) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ResourceARN" : String,
  "RoleARN" : String
}
```

YAML

```
  ResourceARN: String
  RoleARN: String
```

Properties

`ResourceARN`

The Amazon Resource Name (ARN) of the destination Amazon Kinesis stream to write to.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoleARN`

The ARN of the IAM role that Amazon Kinesis Data Analytics can assume to write to the destination stream on your behalf.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationOutput LambdaOutput

The `LambdaOutput` property type specifies a Lambda function as the destination when you are configuring application output.

`LambdaOutput` is a property of the Output (p. 1776) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ResourceARN" : String,
  "RoleARN" : String
}
```

YAML

```
  ResourceARN: String
  RoleARN: String
```

Properties

`ResourceARN`

The Amazon Resource Name (ARN) of the destination Amazon Lambda function to write to.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoleARN`

The ARN of the IAM role that Amazon Kinesis Data Analytics can assume to write to the destination function on your behalf.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationOutput Output

The `Output` property type specifies an array of output configuration objects for an Amazon Kinesis Data Analytics application.

`Output` is a property of the AWS::KinesisAnalytics::ApplicationOutput (p. 1772) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "DestinationSchema" : DestinationSchema (p. 1773),
  "KinesisFirehoseOutput" : KinesisFirehoseOutput (p. 1773),
  "KinesisStreamsOutput" : KinesisStreamsOutput (p. 1774),
  "LambdaOutput" : LambdaOutput (p. 1775),
  "Name" : String
}
```

YAML

```
  DestinationSchema:
    DestinationSchema (p. 1773)
  KinesisFirehoseOutput:
    KinesisFirehoseOutput (p. 1773)
  KinesisStreamsOutput:
    KinesisStreamsOutput (p. 1774)
  LambdaOutput:
    LambdaOutput (p. 1775)
  Name: String
```

Properties

`DestinationSchema`

The data format when records are written to the destination.

Required: Yes

Type: DestinationSchema (p. 1773)

Update requires: No interruption (p. 120)

`KinesisFirehoseOutput`

Identifies an Amazon Kinesis Data Firehose delivery stream as the destination.

Required: Conditional.

Type: KinesisFirehoseOutput (p. 1773)

Update requires: No interruption (p. 120)

`KinesisStreamsOutput`

Identifies an Amazon Kinesis stream as the destination.

Required: Conditional.

Type: KinesisStreamsOutput (p. 1774)

Update requires: No interruption (p. 120)

`LambdaOutput`

Identifies a Lambda function as the destination.

Required: Conditional.

Type: LambdaOutput (p. 1775)

Update requires: No interruption (p. 120)

`Name`

The name of the in-application stream.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

AWS::KinesisAnalytics::ApplicationReferenceDataSource

Use the AWS CloudFormation `AWS::KinesisAnalytics::ApplicationReferenceDataSource` resource to add a reference data source to an existing Amazon Kinesis Data Analytics application. For more information, see `AddApplicationReferenceDataSource` in the *Amazon Kinesis Data Analytics Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::KinesisAnalytics::ApplicationReferenceDataSource",
  "Properties" : {
    "ApplicationName" : String,
    "ReferenceDataSource" : ReferenceDataSource (p. 1783),
  }
}
```

YAML

```
Type: AWS::KinesisAnalytics::ApplicationReferenceDataSource
Properties:
  ApplicationName: String
  ReferenceDataSource:
    ReferenceDataSource (p. 1783)
```

Properties

`ApplicationName`

The name of an existing application.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ReferenceDataSource`

The reference data source, which is an object in your Amazon Simple Storage Service (Amazon S3) bucket.

Required: Yes

Type: ReferenceDataSource (p. 1783)

Update requires: No interruption (p. 120)

Examples

Creating an ApplicationReferenceDataSource Resource

The following example creates an `ApplicationReferenceDataSource` resource:

YAML

```
ApplicationReferenceDataSource:
    Type: AWS::KinesisAnalytics::ApplicationReferenceDataSource
    Properties:
      ApplicationName: !Ref BasicApplication
      ReferenceDataSource:
        TableName: "exampleTable"
        ReferenceSchema:
          RecordColumns:
            - Name: "example"
              SqlType: "VARCHAR(16)"
              Mapping: "$.example"
          RecordFormat:
            RecordFormatType: "JSON"
            MappingParameters:
              JSONMappingParameters:
                RecordRowPath: "$"
        S3ReferenceDataSource:
          BucketARN: !GetAtt S3Bucket.Arn
          FileKey: 'fakeKey'
          ReferenceRoleARN: !GetAtt KinesisAnalyticsRole.Arn
```

Amazon Kinesis Data Analytics ApplicationReferenceDataSource CSVMappingParameters

In AWS CloudFormation, use the `CSVMappingParameters` property to specify additional mapping information when the record format uses delimiters, such as CSV.

`CSVMappingParameters` is a property of the MappingParameters (p. 1780) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "RecordColumnDelimiter" : String,
  "RecordRowDelimiter" : String
}
```

YAML

```
  RecordColumnDelimiter: String
  RecordRowDelimiter: String
```

Properties

`RecordColumnDelimiter`

The column delimiter. For example, in a CSV format, a comma (",") is the typical column delimiter.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RecordRowDelimiter`

The row delimiter. For example, in a CSV format, "\n" is the typical row delimiter.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationReferenceDataSource JSONMappingParameters

Provides additional mapping information when JSON is the record format on the streaming source.

`JSONMappingParameters` is a property of the MappingParameters (p. 1780) parameter.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "RecordRowPath" : String
}
```

YAML

```
  RecordRowPath: String
```

Properties

`RecordRowPath`

Path to the top-level parent that contains the records (e.g., "$".)

Required: Yes

Type: String;

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationReferenceDataSource MappingParameters

When configuring application input at the time of creating or updating an application, provides additional mapping information specific to the record format (such as JSON, CSV, or record fields delimited by some delimiter) on the streaming source.

`MappingParameters` is a property of the RecordFormat (p. 1782) parameter.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "CSVMappingParameters" : CSVMappingParameters (p. 1779),
  "JSONMappingParameters" : JSONMappingParameters (p. 1779)
}
```

YAML

```
  CSVMappingParameters:
    CSVMappingParameters (p. 1779)
  JSONMappingParameters:
    JSONMappingParameters (p. 1779)
```

Properties

`CSVMappingParameters`

Provides additional mapping information when the record format uses delimiters (for example, CSV).

Required: No

Type: CSVMappingParameters (p. 1779)

Update requires: No interruption (p. 120)

`JSONMappingParameters`

Provides additional mapping information when JSON is the record format on the streaming source.

Required: No

Type: JSONMappingParameters (p. 1779)

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationReferenceDataSource RecordColumn

The `RecordColumn` property type specifies the mapping of each data element in the streaming source to the corresponding column in the in-application stream.

`RecordColumn` is a property of the ReferenceSchema (p. 1784) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Mapping" : String,
  "Name" : String,
  "SqlType" : String
}
```

YAML

```
  Mapping: String
  Name: String
  SqlType: String
```

Properties

`Mapping`

The reference to the data element in the streaming input of the reference data source.

Required: No

Type: String;

Update requires: No interruption (p. 120)

`Name`

The name of the column created in the in-application input stream or reference table.

Required: Yes

Type: String;

Update requires: No interruption (p. 120)

`SqlType`

The SQL data type of the column created in the in-application input stream or reference table.

Required: Yes

Type: String;

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationReferenceDataSource RecordFormat

The `RecordFormat` property type specifies the record format and relevant mapping information that should be applied to schematize the records on the stream.

`RecordFormat` is a property of the ReferenceSchema (p. 1784) parameter.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "MappingParameters" : MappingParameters (p. 1780),
  "RecordFormatType" : String
}
```

YAML

```
  MappingParameters:
    MappingParameters (p. 1780)
  RecordFormatType: String
```

Properties

`MappingParameters`

When configuring application input at the time of creating or updating an application, provides additional mapping information specific to the record format (such as JSON, CSV, or record fields delimited by some delimiter) on the streaming source.

Required: No

Type: MappingParameters (p. 1780)

Update requires: No interruption (p. 120)

`RecordFormatType`

The type of record format (CSV or JSON).

Required: Yes

Type: String;

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationReferenceDataSource ReferenceDataSource

The `ReferenceDataSource` property type specifies the reference data source by providing the source information (Amazon S3 bucket name and object key name), the resulting in-application table name that is created, and the necessary schema to map the data elements in the Amazon S3 object to the in-application table.

`ReferenceDataSource` is a property of the AWS::KinesisAnalytics::ApplicationReferenceDataSource (p. 1777) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "TableName" : String,
  "S3ReferenceDataSource" : S3ReferenceDataSource (p. 1785),
  "ReferenceSchema" : ReferenceSchema (p. 1784)
}
```

YAML

```
  TableName: String
  S3ReferenceDataSource:
    S3ReferenceDataSource (p. 1785)
  ReferenceSchema:
    ReferenceSchema (p. 1784)
```

Properties

`TableName`

The name of the in-application table to create.

Required: No

Type: String;

Update requires: No interruption (p. 120)

`S3ReferenceDataSource`

Identifies the Amazon S3 bucket and object that contains the reference data. Also identifies the IAM role that Amazon Kinesis Data Analytics can assume to read this object on your behalf.

Required: No

Type: S3ReferenceDataSource (p. 1785)

Update requires: No interruption (p. 120)

`ReferenceSchema`

Describes the format of the data in the streaming source, and how each data element maps to corresponding columns that are created in the in-application stream.

Required: Yes

Type: ReferenceSchema (p. 1784)

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationReferenceDataSource ReferenceSchema

The `ReferenceSchema` property type specifies the format of the data in the streaming source, and how each data element maps to corresponding columns created in the in-application stream.

`ReferenceSchema` is a property of the ReferenceDataSource (p. 1783) property.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "RecordColumns" : [ RecordColumn (p. 1781), ... ],
  "RecordEncoding" : String,
  "RecordFormat" : RecordFormat (p. 1782)
}
```

YAML

```
  RecordColumns:
    - RecordColumn (p. 1781)
  RecordEncoding: String
  RecordFormat:
    RecordFormat (p. 1782)
```

Properties

`RecordColumns`

A list of Amazon Kinesis Data Analytics ApplicationReferenceDataSource RecordColumn (p. 1781) objects.

Required: Yes

Type: List of RecordColumn (p. 1781)

Update requires: No interruption (p. 120)

`RecordEncoding`

Specifies the encoding of the records in the streaming source; For example, UTF-8.

Required: No

Type: String;

Update requires: No interruption (p. 120)

`RecordFormat`

Specifies the format of the records on the streaming source.

Required: Yes

Type: RecordFormat (p. 1782)

Update requires: No interruption (p. 120)

Amazon Kinesis Data Analytics ApplicationReferenceDataSource S3ReferenceDataSource

The `S3ReferenceDataSource` property type specifies the Amazon S3 bucket and object that contains the reference data for Amazon Kinesis Data Analytics.

`S3ReferenceDataSource` is a property of the ReferenceDataSource (p. 1783) parameter.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "BucketARN" : String,
  "FileKey" : String,
  "ReferenceRoleARN" : String
}
```

YAML

```
  BucketARN: String
  FileKey: String
  ReferenceRoleARN: String
```

Properties

`BucketARN`

The Amazon Resource Name (ARN) of the Amazon S3 bucket.

Required: Yes

Type: String;

Update requires: No interruption (p. 120)

`FileKey`

The object key name containing reference data.

Required: Yes

Type: String;

Update requires: No interruption (p. 120)

`ReferenceRoleARN`

The ARN of the IAM role that the service can assume to read data on your behalf.

Required: Yes

Type: String;

Update requires: No interruption (p. 120)

AWS Key Management Service Resource Types Reference

This section contains reference information for all AWS Key Management Service resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::KMS::data-type-name
```

Topics

- AWS::KMS::Alias (p. 1786)
- AWS::KMS::Key (p. 1788)

AWS::KMS::Alias

The `AWS::KMS::Alias` resource creates a display name for a customer master key (CMK) in AWS Key Management Service (AWS KMS). Using an alias to refer to a key can help you simplify key management. For example, when rotating keys, you can just update the alias mapping instead of tracking and changing key IDs. For more information, see Working with Aliases in the *AWS Key Management Service Developer Guide*.

Topics

- Syntax (p. 1786)
- Properties (p. 1787)
- Return Value (p. 1787)
- Examples (p. 1787)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::KMS::Alias",
  "Properties" : {
    "AliasName" : String,
    "TargetKeyId" : String
  }
}
```

YAML

```
Type: AWS::KMS::Alias
Properties:
```

```
  AliasName: String
  TargetKeyId: String
```

Properties

`AliasName`

The name of the alias. The name must start with `alias` followed by a forward slash, such as `alias/`. You can't specify aliases that begin with `alias/AWS`. These aliases are reserved.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`TargetKeyId`

The ID of the key for which you are creating the alias. Specify the key's globally unique identifier or Amazon Resource Name (ARN). You can't specify another alias.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the alias name, such as `alias/myKeyAlias`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following examples create the `alias/myKeyAlias` alias for the `myKey` AWS KMS key.

JSON

```
"myKeyAlias" : {
  "Type" : "AWS::KMS::Alias",
  "Properties" : {
    "AliasName" : "alias/myKeyAlias",
    "TargetKeyId" : {"Ref":"myKey"}
  }
}
```

YAML

```
myKeyAlias:
  Type: AWS::KMS::Alias
  Properties:
    AliasName: alias/myKeyAlias
    TargetKeyId:
      Ref: myKey
```

AWS::KMS::Key

The `AWS::KMS::Key` resource creates a customer master key (CMK) in AWS Key Management Service (AWS KMS). Users (customers) can use the master key to encrypt their data stored in AWS services that are integrated with AWS KMS or within their applications. For more information, see What is the AWS Key Management Service? in the *AWS Key Management Service Developer Guide*.

Topics

- Syntax (p. 1788)
- Properties (p. 1788)
- Return Values (p. 1789)
- Examples (p. 1790)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::KMS::Key",
  "Properties" : {
    "Description" : String,
    "Enabled" : Boolean,
    "EnableKeyRotation" : Boolean,
    "KeyPolicy" : JSON object,
    "Tags" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: AWS::KMS::Key
Properties:
  Description: String
  Enabled: Boolean
  EnableKeyRotation: Boolean
  KeyPolicy: JSON object
  Tags:
    - Resource Tag
```

Properties

`Description`

A description of the key. Use a description that helps your users decide whether the key is appropriate for a particular task.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Enabled`

Indicates whether the key is available for use. AWS CloudFormation sets this value to `true` by default.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`EnableKeyRotation`

Indicates whether AWS KMS rotates the key. AWS CloudFormation sets this value to `false` by default.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`KeyPolicy`

An AWS KMS key policy to attach to the key. Use a policy to specify who has permission to use the key and which actions they can perform. For more information, see Key Policies in the *AWS Key Management Service Developer Guide*.

Required: Yes

Type: JSON object

Update requires: No interruption (p. 120)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this key. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When you provide the logical ID of this resource to the `Ref` intrinsic function, it returns the key ID, such as `123ab456-a4c2-44cb-95fd-b781f32fbb37`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The ARN of the AWS KMS key, such as `arn:aws:kms:us-west-2:123456789012:key/12a34567-8c90-1defg-af84-0bf06c1747f3`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

The following example creates a custom CMK, which permits the IAM user `Alice` to administer the key and allows `Bob` to use the key for encrypting and decrypting data.

JSON

```
"myKey" : {
  "Type" : "AWS::KMS::Key",
  "Properties" : {
    "Description" : "A sample key",
    "KeyPolicy" : {
      "Version": "2012-10-17",
      "Id": "key-default-1",
      "Statement": [
        {
          "Sid": "Allow administration of the key",
          "Effect": "Allow",
          "Principal": { "AWS": "arn:aws:iam::123456789012:user/Alice" },
          "Action": [
            "kms:Create*",
            "kms:Describe*",
            "kms:Enable*",
            "kms:List*",
            "kms:Put*",
            "kms:Update*",
            "kms:Revoke*",
            "kms:Disable*",
            "kms:Get*",
            "kms:Delete*",
            "kms:ScheduleKeyDeletion",
            "kms:CancelKeyDeletion"
          ],
          "Resource": "*"
        },
        {
          "Sid": "Allow use of the key",
          "Effect": "Allow",
          "Principal": { "AWS": "arn:aws:iam::123456789012:user/Bob" },
          "Action": [
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncrypt*",
            "kms:GenerateDataKey*",
            "kms:DescribeKey"
          ],
          "Resource": "*"
        }
      ]
    }
  }
}
```

YAML

```
myKey:
  Type: AWS::KMS::Key
  Properties:
    Description: "A sample key"
    KeyPolicy:
      Version: "2012-10-17"
      Id: "key-default-1"
```

```
      Statement:
        -
          Sid: "Allow administration of the key"
          Effect: "Allow"
          Principal:
            AWS: "arn:aws:iam::123456789012:user/Alice"
          Action:
            - "kms:Create*"
            - "kms:Describe*"
            - "kms:Enable*"
            - "kms:List*"
            - "kms:Put*"
            - "kms:Update*"
            - "kms:Revoke*"
            - "kms:Disable*"
            - "kms:Get*"
            - "kms:Delete*"
            - "kms:ScheduleKeyDeletion"
            - "kms:CancelKeyDeletion"
          Resource: "*"
        -
          Sid: "Allow use of the key"
          Effect: "Allow"
          Principal:
            AWS: "arn:aws:iam::123456789012:user/Bob"
          Action:
            - "kms:Encrypt"
            - "kms:Decrypt"
            - "kms:ReEncrypt*"
            - "kms:GenerateDataKey*"
            - "kms:DescribeKey"
          Resource: "*"
```

The following example creates a custom CMK with a single tag.

JSON

```
{
  "Resources" : {
    "myKey" : {
      "Type" : "AWS::KMS::Key",
      "Properties" : {
        "KeyPolicy" : {
          "Version": "2012-10-17",
          "Id": "key-default-1",
          "Statement": [
            {
              "Sid": "Enable IAM User Permissions",
              "Effect": "Allow",
              "Principal": {
                "AWS": { "Fn::Join" : ["" , ["arn:aws:iam::", {"Ref" :
 "AWS::AccountId"} ,":root" ]] }
              },
              "Action": "kms:*",
              "Resource": "*"
            }
          ]
        },
        "Tags" : [
          {
            "Key" : {"Ref" : "Key"},
            "Value" : {"Ref" : "Value"}
          }
        ]
```

```
      }
    }
  },
  "Parameters" : {
    "Key" : {
      "Type" : "String"
    },
    "Value" : {
      "Type" : "String"
    }
  }
}
```

YAML

```
Resources:
  myKey:
    Type: AWS::KMS::Key
    Properties:
      KeyPolicy:
        Version: 2012-10-17
        Id: key-default-1
        Statement:
          - Sid: Enable IAM User Permissions
            Effect: Allow
            Principal:
              AWS: !Join
                - ''
                - - 'arn:aws:iam::'
                  - !Ref 'AWS::AccountId'
                  - ':root'

            Resource: '*'
      Tags:
        - Key: !Ref Key
          Value: !Ref Value
Parameters:
  Key:
    Type: String
  Value:
    Type: String
```

AWS Lambda Resource Types Reference

This section contains reference information for all AWS Lambda resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::Lambda::data-type-name
```

Topics

- AWS::Lambda::EventSourceMapping (p. 1793)
- AWS::Lambda::Alias (p. 1795)
- AWS::Lambda::Function (p. 1800)
- AWS::Lambda::Permission (p. 1813)
- AWS::Lambda::Version (p. 1816)

AWS::Lambda::EventSourceMapping

The `AWS::Lambda::EventSourceMapping` resource specifies a stream as an event source for an AWS Lambda (Lambda) function. Lambda invokes the associated function when records are posted to the stream. For more information, see CreateEventSourceMapping in the *AWS Lambda Developer Guide*.

Topics

- Syntax (p. 1793)
- Properties (p. 1793)
- Return Values (p. 1794)
- Example (p. 1794)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Lambda::EventSourceMapping",
  "Properties" : {
    "BatchSize" : Integer,
    "Enabled" : Boolean,
    "EventSourceArn" : String,
    "FunctionName" : String,
    "StartingPosition" : String
  }
}
```

YAML

```
Type: AWS::Lambda::EventSourceMapping
Properties:
  BatchSize: Integer
  Enabled: Boolean
  EventSourceArn: String
  FunctionName: String
  StartingPosition: String
```

Properties

`BatchSize`

The largest number of records that Lambda retrieves from your event source when invoking your function. Your function receives an event with all the retrieved records. For the default and valid values, see CreateEventSourceMapping in the *AWS Lambda Developer Guide*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Enabled`

Indicates whether Lambda begins polling the event source.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`EventSourceArn`

The Amazon Resource Name (ARN) of the event source. Any record added to this stream can invoke the Lambda function. For more information, see CreateEventSourceMapping in the *AWS Lambda Developer Guide*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`FunctionName`

The name or ARN of a Lambda function to invoke when Lambda detects an event on the stream.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`StartingPosition`

The position in a DynamoDB or Kinesis stream where Lambda starts reading. Not required if you set an Amazon SQS queue as the event source. The `AT_TIMESTAMP` value is supported only for Kinesis streams. For valid values, see CreateEventSourceMapping in the *AWS Lambda Developer Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example associates an Kinesis stream with a Lambda function.

JSON

```
"EventSourceMapping": {
  "Type": "AWS::Lambda::EventSourceMapping",
  "Properties": {
    "EventSourceArn" : { "Fn::Join" : [ "", [ "arn:aws:kinesis:", { "Ref" :
 "AWS::Region" }, ":", { "Ref" : "AWS::AccountId" }, ":stream/", { "Ref" :
 "KinesisStream" }] ] },
    "FunctionName" : { "Fn::GetAtt" : ["LambdaFunction", "Arn"] },
    "StartingPosition" : "TRIM_HORIZON"
  }
```

```
}
```

YAML

```
EventSourceMapping:
  Type: AWS::Lambda::EventSourceMapping
  Properties:
    EventSourceArn:
      Fn::Join:
        - ""
        -
          - "arn:aws:kinesis:"
          -
            Ref: "AWS::Region"
          - ":"
          -
            Ref: "AWS::AccountId"
          - ":stream/"
          -
            Ref: "KinesisStream"
    FunctionName:
      Fn::GetAtt:
        - "LambdaFunction"
        - "Arn"
    StartingPosition: "TRIM_HORIZON"
```

AWS::Lambda::Alias

The `AWS::Lambda::Alias` resource creates an alias that points to the version of an AWS Lambda (Lambda) function that you specify. Use aliases when you want to control which version of your function other services or applications invoke. Those services or applications can use your function's alias so that they don't need to be updated whenever you release a new version of your function. For more information, see Introduction to AWS Lambda Aliases in the *AWS Lambda Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Lambda::Alias",
  "Properties" : {
    "Description" : String,
    "FunctionName" : String,
    "FunctionVersion" : String,
    "Name" : String,
    "RoutingConfig" : AliasRoutingConfiguration (p. 1798)
  }
}
```

YAML

```
Type: AWS::Lambda::Alias
Properties:
  Description: String
  FunctionName: String
  FunctionVersion: String
  Name: String
  RoutingConfig:
```

```
    AliasRoutingConfiguration
```

Properties

`Description`

Information about the alias, such as its purpose or the Lambda function that is associated with it.

Required: No

Type: String

Update requires: No interruption (p. 120)

`FunctionName`

The Lambda function that you want to associate with this alias. You can specify the function's name or its Amazon Resource Name (ARN).

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`FunctionVersion`

The version of the Lambda function that you want to associate with this alias.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Name`

A name for the alias.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`RoutingConfig`

Use this parameter to point your alias to two different function versions, allowing you to dictate what percentage of traffic will invoke each version. For more information, see Routing Traffic to Different Function Versions Using Aliases in the *AWS Lambda Developer Guide*.

Required: No

Type: AliasRoutingConfiguration (p. 1798)

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the ARN of the Lambda alias.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Lambda Alias

The following example creates an alias named `TestingForMyApp`. The alias points to the `TestingNewFeature` version of the `MyFunction` Lambda function.

JSON

```
"AliasForMyApp" : {
  "Type" : "AWS::Lambda::Alias",
  "Properties" : {
    "FunctionName" : { "Ref" : "MyFunction" },
    "FunctionVersion" : { "Fn::GetAtt" : [ "TestingNewFeature", "Version" ] },
    "Name" : "TestingForMyApp"
  }
}
```

YAML

```
AliasForMyApp:
  Type: AWS::Lambda::Alias
  Properties:
    FunctionName:
      Ref: "MyFunction"
    FunctionVersion:
      Fn::GetAtt:
        - "TestingNewFeature"
        - "Version"
    Name: "TestingForMyApp"
```

Lambda Alias Update Policy

The following example defines an update policy for an alias.

JSON

```
"Alias": {
  "Type": "AWS::Lambda::Alias",
  "Properties": {
    "FunctionName": {
      "Ref": "LambdaFunction"
    },
    "FunctionVersion": {
      "Fn::GetAtt": [
        "FunctionVersionTwo",
        "Version"
      ]
    },
    "Name": "MyAlias"
  },
  "UpdatePolicy": {
    "CodeDeployLambdaAliasUpdate": {
      "ApplicationName": {
        "Ref": "CodeDeployApplication"
      },
      "DeploymentGroupName": {
        "Ref": "CodeDeployDeploymentGroup"
      },
```

```
      "BeforeAllowTrafficHook": {
        "Ref": "PreHookLambdaFunction"
      },
      "AfterAllowTrafficHook": {
        "Ref": "PreHookLambdaFunction"
      }
    }
  }
}
```

YAML

```
Alias:
  Type: AWS::Lambda::Alias
  Properties:
    FunctionName: !Ref LambdaFunction
    FunctionVersion: !GetAtt FunctionVersionTwo.Version
    Name: MyAlias
  UpdatePolicy:
    CodeDeployLambdaAliasUpdate:
      ApplicationName: !Ref CodeDeployApplication
      DeploymentGroupName: !Ref CodeDeployDeploymentGroup
      BeforeAllowTrafficHook: !Ref PreHookLambdaFunction
      AfterAllowTrafficHook: !Ref PreHookLambdaFunction
```

AWS Lambda Alias AliasRoutingConfiguration

The `AliasRoutingConfiguration` property type specifies two different versions of an AWS Lambda function, allowing you to dictate what percentage of traffic will invoke each version. For more information, see Routing Traffic to Different Function Versions Using Aliases in the *AWS Lambda Developer Guide*.

`AliasRoutingConfiguration` is a property of the AWS::Lambda::Alias (p. 1795) resource type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "AdditionalVersionWeights" : [ VersionWeight (p. 1799), ... ]
}
```

YAML

```
AdditionalVersionWeights:
  - VersionWeight (p. 1799)
```

Properties

`AdditionalVersionWeights`

The percentage of traffic that will invoke the updated function version.

Required: Yes

Type: List of VersionWeight (p. 1799)

Update requires: No interruption (p. 120)

See Also

- Routing Traffic to Different Function Versions Using Aliases in the *AWS Lambda Developer Guide*
- CreateAlias in the *AWS Lambda Developer Guide*
- AliasRoutingConfiguration in the *AWS Lambda Developer Guide*

AWS Lambda Alias VersionWeight

The `VersionWeight` property type specifies the percentages of traffic that will invoke each function versions for an AWS Lambda alias. For more information, see Routing Traffic to Different Function Versions Using Aliases in the *AWS Lambda Developer Guide*.

`VersionWeight` is a property of the AWS::Lambda::Alias (p. 1795) resource type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "FunctionVersion" : String,
  "FunctionWeight" : Double
}
```

YAML

```
FunctionVersion: String
FunctionWeight: Double
```

Properties

`FunctionVersion`

Function version to which the alias points.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`FunctionWeight`

The percentage of traffic that will invoke the function version.

Required: Yes

Type: Double

Update requires: No interruption (p. 120)

See Also

- Routing Traffic to Different Function Versions Using Aliases in the *AWS Lambda Developer Guide*
- AliasRoutingConfiguration in the *AWS Lambda Developer Guide*

AWS::Lambda::Function

The `AWS::Lambda::Function` resource creates an AWS Lambda (Lambda) function that can run code in response to events. For more information, see `CreateFunction` in the *AWS Lambda Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Lambda::Function",
  "Properties" : {
    "Code" : Code,
    "DeadLetterConfig" : DeadLetterConfig (p. 1805),
    "Description" : String,
    "Environment" : Environment (p. 1805),
    "FunctionName" : String,
    "Handler" : String,
    "KmsKeyArn" : String,
    "MemorySize" : Integer,
    "ReservedConcurrentExecutions" : Integer,
    "Role" : String,
    "Runtime" : String,
    "Timeout" : Integer,
    "TracingConfig" : TracingConfig (p. 1812),
    "VpcConfig" : VPCConfig (p. 1813),
    "Tags (p. 1803)" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: "AWS::Lambda::Function"
Properties:
  Code:
    Code
  DeadLetterConfig:
    DeadLetterConfig (p. 1805)
  Description: String
  Environment:
    Environment (p. 1805)
  FunctionName: String
  Handler: String
  KmsKeyArn: String
  MemorySize: Integer
  ReservedConcurrentExecutions: Integer
  Role: String
  Runtime: String
  Timeout: Integer
  TracingConfig:
    TracingConfig (p. 1812)
  VpcConfig:
    VPCConfig (p. 1813)
  Tags (p. 1803):
    Resource Tag
```

Properties

For more information about each property, including defaults, valid values, and constraints, see CreateFunction in the *AWS Lambda Developer Guide*.

`Code`

The source code of your Lambda function. You can point to a file in an Amazon Simple Storage Service (Amazon S3) bucket or specify your source code as inline text.

Required: Yes

Type: AWS Lambda Function Code (p. 1806)

Update requires: No interruption (p. 120)

`DeadLetterConfig`

Configures how Lambda handles events that it can't process. If you don't specify a Dead Letter Queue (DLQ) configuration, Lambda discards events after the maximum number of retries. For more information, see Dead Letter Queues in the *AWS Lambda Developer Guide*.

Required: No

Type: AWS Lambda Function DeadLetterConfig (p. 1805)

Update requires: No interruption (p. 120)

`Description`

A description of the function.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Environment`

Key-value pairs that Lambda caches and makes available for your Lambda functions. Use environment variables to apply configuration changes, such as test and production environment configurations, without changing your Lambda function source code.

Required: No

Type: AWS Lambda Function Environment (p. 1805)

Update requires: No interruption (p. 120)

`FunctionName`

A name for the function. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the function's name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Handler`

The name of the function (within your source code) that Lambda calls to start running your code. For more information, see the `Handler` property in the *AWS Lambda Developer Guide*.

Note
If you specify your source code as inline text by specifying the `ZipFile` property within the `Code` property, specify `index.`*`function_name`* as the handler.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`KmsKeyArn`

The Amazon Resource Name (ARN) of an AWS Key Management Service (AWS KMS) key that Lambda uses to encrypt and decrypt environment variable values.

Type: String

Required: No

Update requires: No interruption (p. 120)

`MemorySize`

The amount of memory, in MB, that is allocated to your Lambda function. Lambda uses this value to proportionally allocate the amount of CPU power. For more information, see Resource Model in the *AWS Lambda Developer Guide*.

Your function use case determines your CPU and memory requirements. For example, a database operation might need less memory than an image processing function. You must specify a value that is greater than or equal to `128`, and it must be a multiple of 64. You cannot specify a size larger than `3008`. The default value is 128 MB.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`ReservedConcurrentExecutions`

The maximum of concurrent executions you want reserved for the function. For more information on reserved concurrency limits, see Managing Concurrency in the *AWS Lambda Developer Guide*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Role`

The Amazon Resource Name (ARN) of the AWS Identity and Access Management (IAM) execution role that Lambda assumes when it runs your code to access AWS services.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Runtime`

The runtime environment for the Lambda function that you are uploading. For valid values, see the Runtime property in the *AWS Lambda Developer Guide*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

> **Note**
> Because Node.js 0.10.32 has been deprecated, you can no longer roll back a template that uses Node.js 0.10.32. If you update a stack to Node.js 0.10.32 and the update fails, AWS CloudFormation won't roll it back.

`Timeout`

The function execution time (in seconds) after which Lambda terminates the function. Because the execution time affects cost, set this value based on the function's expected execution time. By default, `Timeout` is set to `3` seconds. For more information, see the FAQs.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`TracingConfig`

The parent object that contains your Lambda function's tracing settings. By default, the `Mode` property is set to `PassThrough`. For valid values, see the TracingConfig data type in the *AWS Lambda Developer Guide*.

Required: No

Type: AWS Lambda Function TracingConfig (p. 1812)

Update requires: No interruption (p. 120)

`VpcConfig`

If the Lambda function requires access to resources in a VPC, specify a VPC configuration that Lambda uses to set up an elastic network interface (ENI). The ENI enables your function to connect to other resources in your VPC, but it doesn't provide public Internet access. If your function requires Internet access (for example, to access AWS services that don't have VPC endpoints), configure a Network Address Translation (NAT) instance inside your VPC or use an Amazon Virtual Private Cloud (Amazon VPC) NAT gateway. For more information, see NAT Gateways in the *Amazon VPC User Guide*.

> **Note**
> When you specify this property, AWS CloudFormation might not be able to delete the stack if another resource in the template (such as a security group) requires the attached ENI to be deleted before it can be deleted. We recommend that you run AWS CloudFormation with the `ec2:DescribeNetworkInterfaces` permission, which enables AWS CloudFormation to monitor the state of the ENI and to wait (up to 40 minutes) for Lambda to delete the ENI.

Required: No

Type: AWS Lambda Function VpcConfig (p. 1813)

Update requires: No interruption (p. 120)

`Tags`

An arbitrary set of tags (key–value pairs) for this Lambda function.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

In the following sample, the `Ref` function returns the name of the `AMILookUp` function, such as `MyStack-AMILookUp-NT5EUXTNTXXD`.

```
{ "Ref": "AMILookUp" }
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

The ARN of the Lambda function, such as `arn:aws:lambda:us-west-2:123456789012:MyStack-AMILookUp-NT5EUXTNTXXD`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example uses a packaged file in an S3 bucket to create a Lambda function.

JSON

```
"AMIIDLookup": {
  "Type": "AWS::Lambda::Function",
  "Properties": {
    "Handler": "index.handler",
    "Role": { "Fn::GetAtt" : ["LambdaExecutionRole", "Arn"] },
    "Code": {
      "S3Bucket": "lambda-functions",
      "S3Key": "amilookup.zip"
    },
    "Runtime": "nodejs4.3",
    "Timeout": 25,
    "TracingConfig": {
      "Mode": "Active"
   }
  }
}
```

YAML

```
AMIIDLookup:
  Type: "AWS::Lambda::Function"
  Properties:
    Handler: "index.handler"
    Role:
      Fn::GetAtt:
        - "LambdaExecutionRole"
        - "Arn"
```

```
    Code:
      S3Bucket: "lambda-functions"
      S3Key: "amilookup.zip"
    Runtime: "nodejs4.3"
    Timeout: 25
    TracingConfig:
      Mode: "Active"
```

Related Resources

For more information about how you can use a Lambda function with AWS CloudFormation custom resources, see AWS Lambda-backed Custom Resources (p. 446).

For a sample template, see AWS Lambda Template (p. 406).

AWS Lambda Function DeadLetterConfig

`DeadLetterConfig` is a property of the AWS::Lambda::Function (p. 1800) resource that specifies a Dead Letter Queue (DLQ) that AWS Lambda (Lambda) sends events to when it can't process them. For example, you can send unprocessed events to an Amazon Simple Notification Service (Amazon SNS) topic, where you can take further action.

Syntax

JSON

```
{
  "TargetArn" : String
}
```

YAML

```
TargetArn: String
```

Properties

`TargetArn`

The Amazon Resource Name (ARN) of a resource where Lambda delivers unprocessed events, such as an Amazon SNS topic or Amazon Simple Queue Service (Amazon SQS) queue. For the Lambda function execution role, you must explicitly provide the relevant permissions so that access to your DLQ resource is part of the execution role for your Lambda function.

Required: No

Type: String

AWS Lambda Function Environment

`Environment` is a property of the AWS::Lambda::Function (p. 1800) resource that specifies key-value pairs that the AWS Lambda (Lambda) function can access so that you can apply configuration changes, such as test and production environment configurations, without changing the function code.

Syntax

JSON

```
{
```

```
  "Variables" : { String:String, ... }
}
```

YAML

```
Variables:
  String: String
```

Properties

`Variables`

A map of key-value pairs that the Lambda function can access.

Required: No

Type: Mapping of key-value pairs

AWS Lambda Function Code

`Code` is a property of the AWS::Lambda::Function (p. 1800) resource that enables you to specify the source code of an AWS Lambda function. Your source code can be located in either the template or a file in an Amazon Simple Storage Service (Amazon S3) bucket. For `nodejs4.3`, `nodejs6.10`, `python2.7`, and `python3.6` runtime environments only, you can provide source code as inline text in your template.

> **Note**
> To update a Lambda function whose source code is in an Amazon S3 bucket, you must trigger an update by updating the `S3Bucket`, `S3Key`, or `S3ObjectVersion` property. Updating the source code alone doesn't update the function.

Syntax

JSON

```
{
  "S3Bucket" : String,
  "S3Key" : String,
  "S3ObjectVersion" : String,
  "ZipFile" : String
}
```

YAML

```
S3Bucket: String
S3Key: String
S3ObjectVersion: String
ZipFile: String
```

Properties

`S3Bucket`

The name of the Amazon S3 bucket where the `.zip` file that contains your deployment package is stored. This bucket must reside in the same AWS Region that you're creating the Lambda function in. You can specify a bucket from another AWS account as long as the Lambda function and the bucket are in the same region.

Note
The `cfn-response` module isn't available for source code that's stored in Amazon S3 buckets. To send responses, write your own functions.

Required: Conditional Specify both the `S3Bucket` and `S3Key` properties, or specify the `ZipFile` property.

Type: String

`S3Key`

The location and name of the `.zip` file that contains your source code. If you specify this property, you must also specify the `S3Bucket` property.

Required: Conditional You must specify both the `S3Bucket` and `S3Key` properties, or specify the `ZipFile` property.

Type: String

`S3ObjectVersion`

If you have S3 versioning enabled, the version ID of the `.zip` file that contains your source code. You can specify this property only if you specify the `S3Bucket` and `S3Key` properties.

Required: No

Type: String

`ZipFile`

For `nodejs4.3`, `nodejs6.10`, `python2.7`, and `python3.6` runtime environments, the source code of your Lambda function. You can't use this property with other runtime environments.

You can specify up to 4096 characters. You must precede certain special characters in your source code (such as quotation marks (`"`), newlines (`\n`), and tabs (`\t`)) with a backslash (`\`). For a list of special characters, see http://json.org/.

If you specify a function that interacts with an AWS CloudFormation custom resource, you don't have to write your own functions to send responses to the custom resource that invoked the function. AWS CloudFormation provides a response module that simplifies sending responses. For more information, see `cfn-response` Module (p. 1807).

Required: Conditional You must specify both the `S3Bucket` and `S3Key` properties, or specify the `ZipFile` property.

Type: String

`cfn-response` Module

When you use the `ZipFile` property to specify your function's source code and that function interacts with an AWS CloudFormation custom resource, you can load the `cfn-response` module to send responses to those resources. The module contains a `send` method, which sends a response object (p. 455) to a custom resource by way of an Amazon S3 presigned URL (the `ResponseURL`).

After executing the `send` method, the Lambda function terminates, so anything you write after that method is ignored.

Note
The `cfn-response` module is available only when you use the `ZipFile` property to write your source code. It isn't available for source code that's stored in Amazon S3 buckets. For code in buckets, you must write your own functions to send responses.

Loading the `cfn-response` Module

For the `nodejs4.3` or `nodejs6.10` runtime environment, use the `require()` function to load the `cfn-response` module. For example, the following code example creates a `cfn-response` object with the name `response`:

```
var response = require('cfn-response');
```

For `python2.7` or `python3.6` environments, use the `import` statement to load the `cfnresponse` module, as shown in the following example:

> **Note**
> Use this exact import statement. If you use other variants of the import statement, AWS CloudFormation doesn't include the response module.

```
import cfnresponse
```

`send` Method Parameters

You can use the following parameters with the `send` method.

`event`

The fields in a custom resource request (p. 456).

`context`

An object, specific to Lambda functions, that you can use to specify when the function and any callbacks have completed execution, or to access information from within the Lambda execution environment. For more information, see Programming Model (Node.js) in the *AWS Lambda Developer Guide*.

`responseStatus`

Whether the function successfully completed. Use the `cfnresponse` module constants to specify the status: `SUCCESS` for successful executions and `FAILED` for failed executions.

`responseData`

The `Data` field of a custom resource response object (p. 455). The data is a list of name-value pairs.

`physicalResourceId`

Optional. The unique identifier of the custom resource that invoked the function. By default, the module uses the name of the Amazon CloudWatch Logs log stream that's associated with the Lambda function.

`noEcho`

Optional. Indicates whether to mask the output of the custom resource when it's retrieved by using the `Fn::GetAtt` function. If set to `true`, all returned values are masked with asterisks (*****). By default, this value is `false`.

Examples

Node.js

In the following Node.js example, the inline Lambda function takes an input value and multiplies it by 5. Inline functions are especially useful for smaller functions because they allow you to specify the source code directly in the template, instead of creating a package and uploading it to an Amazon S3 bucket.

The function uses the `cfn-response send` method to send the result back to the custom resource that invoked it.

JSON

```
"ZipFile": { "Fn::Join": ["", [
  "var response = require('cfn-response');",
  "exports.handler = function(event, context) {",
  "  var input = parseInt(event.ResourceProperties.Input);",
  "  var responseData = {Value: input * 5};",
  "  response.send(event, context, response.SUCCESS, responseData);",
  "};"
]]}
```

YAML

```
ZipFile: >
  var response = require('cfn-response');
  exports.handler = function(event, context) {
    var input = parseInt(event.ResourceProperties.Input);
    var responseData = {Value: input * 5};
    response.send(event, context, response.SUCCESS, responseData);
  };
```

Python

As in the preceding example, in the following Python example (the example works in both version 2.7 and 3.6), the inline Lambda function takes an integer value and multiplies it by 5.

JSON

```
"ZipFile" : { "Fn::Join" : ["\n", [
  "import json",
  "import cfnresponse",
  "def handler(event, context):",
  "   responseValue = int(event['ResourceProperties']['Input']) * 5",
  "   responseData = {}",
  "   responseData['Data'] = responseValue",
  "   cfnresponse.send(event, context, cfnresponse.SUCCESS, responseData,
 \"CustomResourcePhysicalID\")"
]]}
```

YAML

```
ZipFile: |
  import json
  import cfnresponse
  def handler(event, context):
    responseValue = int(event['ResourceProperties']['Input']) * 5
    responseData = {}
    responseData['Data'] = responseValue
    cfnresponse.send(event, context, cfnresponse.SUCCESS, responseData,
 "CustomResourcePhysicalID")
```

Module Source Code

The following is the response module source code for the `nodejs4.3` or `nodejs6.10` runtime environment. Review it to understand what the module does and for help with implementing your own response functions.

```

exports.SUCCESS = "SUCCESS";
exports.FAILED = "FAILED";

exports.send = function(event, context, responseStatus, responseData, physicalResourceId,
 noEcho) {

    var responseBody = JSON.stringify({
        Status: responseStatus,
        Reason: "See the details in CloudWatch Log Stream: " + context.logStreamName,
        PhysicalResourceId: physicalResourceId || context.logStreamName,
        StackId: event.StackId,
        RequestId: event.RequestId,
        LogicalResourceId: event.LogicalResourceId,
        NoEcho: noEcho || false,
        Data: responseData
    });

    console.log("Response body:\n", responseBody);

    var https = require("https");
    var url = require("url");

    var parsedUrl = url.parse(event.ResponseURL);
    var options = {
        hostname: parsedUrl.hostname,
        port: 443,
        path: parsedUrl.path,
        method: "PUT",
        headers: {
            "content-type": "",
            "content-length": responseBody.length
        }
    };

    var request = https.request(options, function(response) {
        console.log("Status code: " + response.statusCode);
        console.log("Status message: " + response.statusMessage);
        context.done();
    });

    request.on("error", function(error) {
        console.log("send(..) failed executing https.request(..): " + error);
        context.done();
    });

    request.write(responseBody);
    request.end();
}
```

The following is the response module source code for the `python3.6` environment:

```
#  Copyright 2016 Amazon Web Services, Inc. or its affiliates. All Rights Reserved.
#  This file is licensed to you under the AWS Customer Agreement (the "License").
#  You may not use this file except in compliance with the License.
#  A copy of the License is located at http://aws.amazon.com/agreement/ .

```

AWS Lambda Function TracingConfig

`TracingConfig` is a property of the AWS::Lambda::Function (p. 1800) resource that configures tracing settings for your AWS Lambda (Lambda) function. For more information about tracing Lambda functions, see Tracing Lambda-Based Applications with AWS X-Ray in the *AWS Lambda Developer Guide*.

Syntax

JSON

```
{
  "Mode" : String
}
```

YAML

```
Mode:
  String
```

Properties

`Mode`

Specifies how Lambda traces a request. The default mode is `PassThrough`. For more information, see `TracingConfig` in the *AWS Lambda Developer Guide*.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Lambda Function VpcConfig

`VpcConfig` is a property of the AWS::Lambda::Function (p. 1800) resource that enables your AWS Lambda (Lambda) function to access resources in a VPC. For more information, see Configuring a Lambda Function to Access Resources in an Amazon VPC in the *AWS Lambda Developer Guide*.

Syntax

JSON

```
{
  "SecurityGroupIds" : [ String, ... ],
  "SubnetIds" : [ String, ... ]
}
```

YAML

```
SecurityGroupIds:
  - String
SubnetIds:
  - String
```

Properties

`SecurityGroupIds`

A list of one or more security groups IDs in the VPC that includes the resources to which your Lambda function requires access.

Required: Yes

Type: List of String values

`SubnetIds`

A list of one or more subnet IDs in the VPC that includes the resources to which your Lambda function requires access.

Required: Yes

Type: List of String values

AWS::Lambda::Permission

The `AWS::Lambda::Permission` resource associates a policy statement with a specific AWS Lambda (Lambda) function's access policy. The function policy grants a specific AWS service or application permission to invoke the function. For more information, see AddPermission in the *AWS Lambda Developer Guide*.

Topics

- Syntax (p. 1814)
- Properties (p. 1814)
- Example (p. 1815)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Lambda::Permission",
  "Properties" : {
    "Action" : String,
    "EventSourceToken" : String,
    "FunctionName" : String,
    "Principal" : String,
    "SourceAccount" : String,
    "SourceArn" : String
  }
}
```

YAML

```
Type: AWS::Lambda::Permission
Properties:
  Action: String
  EventSourceToken: String
  FunctionName: String
  Principal: String
  SourceAccount: String
  SourceArn: String
```

Properties

For more information and current valid values, see AddPermission in the *AWS Lambda Developer Guide*.

`Action`

The Lambda actions that you want to allow in this statement. For example, you can specify `lambda:CreateFunction` to specify a certain action, or use a wildcard (`lambda:*`) to grant permission to all Lambda actions. For a list of actions, see Actions and Condition Context Keys for AWS Lambda in the *IAM User Guide*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`EventSourceToken`

A unique token that must be supplied by the principal invoking the function.

Required: No

Type: String

Update requires: Replacement (p. 121)

`FunctionName`

The name (physical ID), Amazon Resource Name (ARN), or alias ARN of the Lambda function that you want to associate with this statement. Lambda adds this statement to the function's access policy.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Principal`

The entity for which you are granting permission to invoke the Lambda function. This entity can be any valid AWS service principal, such as `s3.amazonaws.com` or `sns.amazonaws.com`, or, if you are granting cross-account permission, an AWS account ID. For example, you might want to allow a custom application in another AWS account to push events to Lambda by invoking your function.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SourceAccount`

The AWS account ID (without hyphens) of the source owner. For example, if you specify an S3 bucket in the `SourceArn` property, this value is the bucket owner's account ID. You can use this property to ensure that all source principals are owned by a specific account.

> **Important**
> This property is not supported by all event sources. For more information, see the `SourceAccount` parameter for the AddPermission action in the *AWS Lambda Developer Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SourceArn`

The ARN of a resource that is invoking your function. When granting Amazon Simple Storage Service (Amazon S3) permission to invoke your function, specify this property with the bucket ARN as its value. This ensures that events generated only from the specified bucket, not just any bucket from any AWS account that creates a mapping to your function, can invoke the function.

> **Important**
> This property is not supported by all event sources. For more information, see the `SourceArn` parameter for the AddPermission action in the *AWS Lambda Developer Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

Example

The following example grants an S3 bucket permission to invoke a Lambda function.

JSON

```
"LambdaInvokePermission": {
 "Type": "AWS::Lambda::Permission",
 "Properties": {
  "FunctionName": {
   "Fn::GetAtt": [
    "MyLambdaFunction",
    "Arn"
```

```
    ]
  },
  "Action": "lambda:InvokeFunction",
  "Principal": "s3.amazonaws.com",
  "SourceAccount": {
   "Ref": "AWS::AccountId"
  },
  "SourceArn": {
   "Fn::GetAtt": [
    "MyBucket",
    "Arn"
   ]
  }
 }
}
```

YAML

```
LambdaInvokePermission:
  Type: AWS::Lambda::Permission
  Properties:
    FunctionName: !GetAtt
      - MyLambdaFunction
      - Arn
    Action: 'lambda:InvokeFunction'
    Principal: s3.amazonaws.com
    SourceAccount: !Ref 'AWS::AccountId'
    SourceArn: !GetAtt
      - MyBucket
      - Arn
```

AWS::Lambda::Version

The `AWS::Lambda::Version` resource publishes a specified version of an AWS Lambda (Lambda) function. When publishing a new version of your function, Lambda copies the latest version of your function. For more information, see Introduction to AWS Lambda Versioning in the *AWS Lambda Developer Guide*.

Topics

- Syntax (p. 1816)
- Properties (p. 1817)
- Return Values (p. 1817)
- Example (p. 1818)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Lambda::Version",
  "Properties" : {
    "CodeSha256" : String,
    "Description" : String,
    "FunctionName" : String
  }
}
```

YAML

```
Type: AWS::Lambda::Version
Properties:
  CodeSha256 : String
  Description : String
  FunctionName : String
```

Properties

`CodeSha256`

The SHA-256 hash of the deployment package that you want to publish. This value must match the SHA-256 hash of the `$LATEST` version of the function. Specify this property to validate that you are publishing the correct package.

Required: No

Type: String

Update requires: Updates are not supported.

`Description`

A description of the version you are publishing. If you don't specify a value, Lambda copies the description from the `$LATEST` version of the function.

Required: No

Type: String

Update requires: Updates are not supported.

`FunctionName`

The Lambda function for which you want to publish a version. You can specify the function's name or its Amazon Resource Name (ARN).

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the ARN of the Lambda version, such as `arn:aws:lambda:us-west-2:123456789012:function:helloworld:1`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of the specified resource type.

`Version`

The published version of a Lambda version, such as `1`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example publishes a new version of the `MyFunction` Lambda function.

JSON

```
"TestingNewFeature" : {
  "Type" : "AWS::Lambda::Version",
  "Properties" : {
    "FunctionName" : { "Ref" : "MyFunction" },
    "Description" : "A test version of MyFunction"
  }
}
```

YAML

```
TestingNewFeature:
  Type: AWS::Lambda::Version
  Properties:
    FunctionName:
      Ref: "MyFunction"
    Description: "A test version of MyFunction"
```

Amazon Neptune Resource Types Reference

This section contains reference information for all Amazon Neptune resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::Neptune::data-type-name
```

Topics

- AWS::Neptune::DBCluster (p. 1818)
- AWS::Neptune::DBClusterParameterGroup (p. 1822)
- AWS::Neptune::DBInstance (p. 1824)
- AWS::Neptune::DBParameterGroup (p. 1829)
- AWS::Neptune::DBSubnetGroup (p. 1831)

AWS::Neptune::DBCluster

The `AWS::Neptune::DBCluster` resource creates an Amazon Neptune DB cluster. Neptune is a fully managed graph database.

> **Note**
> Currently, you can create this resource only in AWS Regions in which Amazon Neptune is supported.

The default `DeletionPolicy` for `AWS::Neptune::DBCluster` resources is `Snapshot`. For more information about how AWS CloudFormation deletes resources, see DeletionPolicy Attribute (p. 2273).

Topics

- Syntax (p. 1819)
- Properties (p. 1819)
- Return Values (p. 1822)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Neptune::DBCluster",
  "Properties" :
  {
    "AvailabilityZones" : [ String, ... ],
    "BackupRetentionPeriod" : Integer,
    "DBClusterIdentifier" : String,
    "DBClusterParameterGroupName" : String,
    "DBSubnetGroupName" : String,
    "IamAuthEnabled" : Boolean,
    "KmsKeyId" : String,
    "Port" : Integer,
    "PreferredBackupWindow" : String,
    "PreferredMaintenanceWindow" : String,
    "SnapshotIdentifier" : String,
    "StorageEncrypted" : Boolean,
    "Tags" : [ Resource Tag, ... ],
    "VpcSecurityGroupIds" : [ String, ... ]
  }
}
```

YAML

```
Type: "AWS::Neptune::DBCluster"
Properties:
  AvailabilityZones:
    - String
  BackupRetentionPeriod: Integer
  DBClusterIdentifier: String
  DBClusterParameterGroupName: String
  DBSubnetGroupName: String
  IamAuthEnabled: Boolean
  KmsKeyId: String
  Port: Integer
  PreferredBackupWindow: String
  PreferredMaintenanceWindow: String
  SnapshotIdentifier: String
  StorageEncrypted: Boolean
  Tags:
    - Resource Tag
  VpcSecurityGroupIds:
    - String
```

Properties

`AvailabilityZones`

A list of Availability Zones in which DB instances in the cluster can be created.

Required: No

Type: String

Update requires: Replacement (p. 121)

`BackupRetentionPeriod`

The number of days for which automatic backups are retained. For more information, see CreateDBCluster in the *Amazon Neptune User Guide*.

Required: No

Type: Integer

Update requires: No interruption (p. 120) or some interruption (p. 121). For more information, see ModifyDBInstance in the *Amazon Neptune User Guide*.

`DBClusterIdentifier`

The DB cluster identifier. This parameter is stored as a lowercase string.

Constraints:

- Must contain from 1 to 63 letters, numbers, or hyphens.
- First character must be a letter.
- Cannot end with a hyphen or contain two consecutive hyphens.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBClusterParameterGroupName`

The name of the DB cluster parameter group to associate with this DB cluster.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`DBSubnetGroupName`

A DB subnet group that you want to associate with this DB cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`IamAuthEnabled`

Enable IAM authentication and authorization on this cluster.

Type: Boolean

Update requires: No interruption (p. 120)

`KmsKeyId`

The Amazon Resource Name (ARN) of the AWS Key Management Service (AWS KMS) master key that is used to encrypt the database instances in the DB cluster, such as `arn:aws:kms:us-east-1:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef`. If you enable the `StorageEncrypted` property but don't specify this property, the default master key is used. If you specify this property, you must set the `StorageEncrypted` property to `true`.

If you specify the `SnapshotIdentifier`, do not specify this property. The value is inherited from the snapshot DB cluster.

Required: No

Type: String

Update requires: Replacement (p. 121).

`Port`

The port number on which the DB instances in the cluster can accept connections.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`PreferredBackupWindow`

If automated backups are enabled (see the `BackupRetentionPeriod` property), the daily time range in UTC during which you want to create automated backups.

For valid values, see the `PreferredBackupWindow` parameter of the CreateDBInstance action.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PreferredMaintenanceWindow`

The weekly time range (in UTC) during which system maintenance can occur.

For valid values, see the `PreferredMaintenanceWindow` parameter of the CreateDBInstance action.

Required: No

Type: String

Update requires: No interruption (p. 120) or some interruption (p. 121). For more information, see ModifyDBInstance.

`SnapshotIdentifier`

The identifier for the DB cluster snapshot from which you want to restore.

Required: No

Type: String

Update requires: Replacement (p. 121)

`StorageEncrypted`

Indicates whether the DB instances in the cluster are encrypted.

If you specify the `SnapshotIdentifier` property, do not specify this property. The value is inherited from the snapshot DB cluster.

Required: Conditional. If you specify the `KmsKeyId` property, you must enable encryption.

Type: Boolean

Update requires: Replacement (p. 121)

`Tags`

The tags that you want to attach to this DB cluster.

Required: No

Type: A list of resource tags (p. 2258).

Update requires: No interruption (p. 120)

`VpcSecurityGroupIds`

A list of VPC security groups to associate with this DB cluster.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Endpoint`

The connection endpoint for the DB cluster. For example: `mystack-mydbcluster-1apw1j4phylrk.cg034hpkmmjt.us-east-2.rds.amazonaws.com`

`Port`

The port number on which the DB cluster accepts connections. For example: `8182`

`ReadEndpoint`

The reader endpoint for the DB cluster. For example: `mystack-mydbcluster-ro-1apw1j4phylrk.cg034hpkmmjt.us-east-2.rds.amazonaws.com`

`ClusterResourceId`

The resource id for the DB cluster; for example: `cluster-ABCD1234EFGH5678IJKL90MNOP`. The cluster ID uniquely identifies the cluster and is used in things like IAM authentication policies.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

AWS::Neptune::DBClusterParameterGroup

The `AWS::Neptune::DBClusterParameterGroup` resource creates a new Amazon Neptune DB cluster parameter group.

Note
Applying a parameter group to a DB cluster might require instances to reboot, resulting in a database outage while the instances reboot.

Topics

- Syntax (p. 1823)
- Properties (p. 1823)
- Return Values (p. 1824)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Neptune::DBClusterParameterGroup",
  "Properties" : {
    "Description" : String,
    "Parameters" : DBParameters,
    "Family" : String,
    "Tags" : [ Resource Tag, ... ],
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::Neptune::DBClusterParameterGroup"
Properties:
  Description: String
  Parameters: DBParameters
  Family : String
  Tags:
    Resource Tag
  Name : String
```

Properties

`Description`

A friendly description for this DB cluster parameter group.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Parameters`

The parameters to set for this DB cluster parameter group.

Changes to dynamic parameters are applied immediately. Changes to static parameters require a reboot without failover to the DB instance that is associated with the parameter group before the change can take effect.

Required: Yes

Type: A JSON object consisting of string key-value pairs, as shown in the following example:

```
"Parameters" : {
   "Key1" : "Value1",
   "Key2" : "Value2",
   "Key3" : "Value3"
}
```

Update requires: No interruption (p. 120) or some interruption (p. 121), depending on the parameters that you update.

`Family`

Must be `neptune1`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

The tags that you want to attach to this parameter group.

Required: No

Type: A list of resource tags (p. 2258)

Update requires: Updates are not supported.

`Name`

A friendly name for the cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::Neptune::DBInstance

The `AWS::Neptune::DBInstance` type creates an Amazon Neptune DB instance.

> **Important**
> If a DB instance is deleted or replaced during an update, AWS CloudFormation deletes all automated snapshots. However, it retains manual DB snapshots. During an update that requires replacement, you can apply a stack policy to prevent DB instances from being replaced. For more information, see Prevent Updates to Stack Resources (p. 143).

Topics

- Syntax (p. 1825)

- Properties (p. 1825)
- Updating and Deleting AWS::Neptune::DBInstance Resources (p. 1828)
- Return Values (p. 1828)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Neptune::DBInstance",
  "Properties" :
  {
    "AllowMajorVersionUpgrade" : Boolean,
    "AutoMinorVersionUpgrade (p. 1825)" : Boolean,
    "AvailabilityZone (p. 1826)" : String,
    "DBClusterIdentifier" : String,
    "DBInstanceClass (p. 1826)" : String,
    "DBInstanceIdentifier" : String,
    "DBParameterGroupName (p. 1826)" : String,
    "DBSnapshotIdentifier (p. 1827)" : String,
    "DBSubnetGroupName (p. 1827)" : String,
    "PreferredMaintenanceWindow (p. 1827)" : String,
    "Tags (p. 1827)" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: "AWS::Neptune::DBInstance"
Properties:
  AllowMajorVersionUpgrade: Boolean
  AutoMinorVersionUpgrade (p. 1825): Boolean
  AvailabilityZone (p. 1826): String
  DBClusterIdentifier: String
  DBInstanceClass (p. 1826): String
  DBInstanceIdentifier: String
  DBParameterGroupName (p. 1826): String
  DBSnapshotIdentifier (p. 1827): String
  DBSubnetGroupName (p. 1827): String
  PreferredMaintenanceWindow (p. 1827) : String
  Tags (p. 1827):
    Resource Tag
```

Properties

`AllowMajorVersionUpgrade`

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`AutoMinorVersionUpgrade`

Indicates that minor engine upgrades are applied automatically to the DB instance during the maintenance window. The default value is `true`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120) or some interruption (p. 121).

`AvailabilityZone`

The name of the Availability Zone where the DB instance is located. You can't set the `AvailabilityZone` parameter if the `MultiAZ` parameter is set to `true`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBClusterIdentifier`

The name of an existing DB cluster that this instance is associated with.

Neptune assigns the first DB instance in the cluster as the primary, and additional DB instances as replicas.

If you specify this property, the default deletion policy is `Delete`. Otherwise, the default deletion policy is `Snapshot`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBInstanceClass`

The name of the compute and memory capacity classes of the DB instance.

Required: Yes

Type: String

Update requires: Some interruptions (p. 121)

`DBInstanceIdentifier`

A name for the DB instance. If you specify a name, AWS CloudFormation converts it to lowercase. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the DB instance. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBParameterGroupName`

The name of an existing DB parameter group or a reference to an AWS::Neptune::DBParameterGroup (p. 1829) resource created in the template.

Required: No

Type: String

Update requires: No interruption (p. 120) or some interruption (p. 121). If any of the data members of the referenced parameter group are changed during an update, the DB instance might need to be restarted, which causes some interruption. If the parameter group contains static parameters, whether they were changed or not, an update triggers a reboot.

`DBSnapshotIdentifier`

This parameter is not supported.

`AWS::Neptune::DBInstance` does not support restoring from snapshots.

`AWS::Neptune::DBCluster` supports restoring from snapshots. For more information, see AWS::Neptune::DBCluster (p. 1818).

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBSubnetGroupName`

A DB subnet group to associate with the DB instance. If you update this value, the new subnet group must be a subnet group in a new virtual private cloud (VPC).

Required: No

Type: String

Update requires: Replacement (p. 121)

`PreferredMaintenanceWindow`

The weekly time range (in UTC) during which system maintenance can occur. For valid values, see the `PreferredMaintenanceWindow` parameter for the CreateDBInstance action in the *Amazon Neptune User Guide*.

> **Note**
> This property applies when AWS CloudFormation initially creates the DB instance. If you use AWS CloudFormation to update the DB instance, those updates are applied immediately.

Required: No

Type: String

Update requires: No interruption (p. 120) or some interruption (p. 121). For more information, see ModifyDBInstance in the *Amazon Neptune User Guide*.

`StorageEncrypted`

Indicates whether the DB instance is encrypted.

If you specify the `DBClusterIdentifier`, `DBSnapshotIdentifier`, or `SourceDBInstanceIdentifier` property, don't specify this property. The value is inherited from the cluster, snapshot, or source DB instance.

Required: Conditional. If you specify the `KmsKeyId` property, you must enable encryption.

Type: Boolean

Update requires: Replacement (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) for this DB instance.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Updating and Deleting AWS::Neptune::DBInstance Resources

Updating DB Instances

When properties labeled "*Update requires*: Replacement (p. 121)" are updated, AWS CloudFormation first creates a replacement DB instance, changes references from other dependent resources to point to the replacement DB instance, and finally deletes the old DB instance.

Important
We highly recommend that you take a snapshot of the database before updating the stack. If you don't, you lose the data when AWS CloudFormation replaces your DB instance. To preserve your data, perform the following procedure:

1. Deactivate any applications that are using the DB instance so that there's no activity on the DB instance.
2. Create a snapshot of the DB instance.
3. If you want to restore your instance using a DB snapshot, modify the updated template with your DB instance changes and add the `DBSnapshotIdentifier` property with the ID of the DB snapshot that you want to use.
4. Update the stack.

Deleting DB Instances

You can set a deletion policy for your DB instance to control how AWS CloudFormation handles the instance when the stack is deleted. For Neptune DB instances, you can choose to *retain* the instance, to *delete* the instance, or to *create a snapshot* of the instance. The default AWS CloudFormation behavior depends on the `DBClusterIdentifier` property:

- For `AWS::Neptune::DBInstance` resources that don't specify the `DBClusterIdentifier` property, AWS CloudFormation saves a snapshot of the DB instance.
- For `AWS::Neptune::DBInstance` resources that do specify the `DBClusterIdentifier` property, AWS CloudFormation deletes the DB instance.

For more information, see DeletionPolicy Attribute (p. 2273).

Return Values

Ref

When you provide the Neptune DB instance's logical name to the `Ref` intrinsic function, `Ref` returns the `DBInstanceIdentifier`. For example: `mystack-mydb-ea5ugmfvuaxg`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

- **Endpoint**

  The connection endpoint for the database. For example: `mystack-mydb-1apw1j4phylrk.cg034hpkmmjt.us-east-2.rds.amazonaws.com`.

- **Port**

  The port number on which the database accepts connections. For example: `8182`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

AWS::Neptune::DBParameterGroup

Creates a custom parameter group for DB instances.

This type can be declared in a template and referenced in the `DBParameterGroupName` parameter of AWS::Neptune::DBInstance (p. 1824).

> **Note**
> Applying a parameter group to a DB instance might require the instance to reboot, resulting in a database outage for the duration of the reboot.

Topics

- Syntax (p. 1829)
- Properties (p. 1829)
- Return Values (p. 1830)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::Neptune::DBParameterGroup",
   "Properties" : {
      "Description (p. 1829)" : String,
      "Parameters (p. 1830)" : DBParameters,
      "Family" : String,
      "Tags" : [ Resource Tag, ... ],
      "Name" : String
   }
}
```

YAML

```
Type: "AWS::Neptune::DBParameterGroup"
Properties:
  Description (p. 1829): String
  Parameters (p. 1830):
    DBParameters
  Family : String
  Tags:
    - Resource Tag
  Name : String
```

Properties

`Description`

A friendly description of the DB parameter group. For example, `"My Parameter Group"`.

Required: Yes

Type: String

Update requires: Updates are not supported.

`Parameters`

The parameters to set for this DB parameter group.

Required: No

Type: A JSON object consisting of string key-value pairs, as shown in the following example:

```
"Parameters" : {
   "Key1" : "Value1",
   "Key2" : "Value2",
   "Key3" : "Value3"
}
```

Update requires: No interruption (p. 120) or some interruption (p. 121). Changes to dynamic parameters are applied immediately. During an update, if you have static parameters (whether they were changed or not), it triggers AWS CloudFormation to reboot the associated DB instance without failover.

`Family`

Must be `neptune1`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

The tags that you want to attach to the DB parameter group.

Required: No

Type: A list of resource tags (p. 2258).

Update requires: No interruption (p. 120)

`Name`

A friendly name for the cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyDBParameterGroup" }
```

For the `RDS::DBParameterGroup` with the logical ID "`MyDBParameterGroup`," `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::Neptune::DBSubnetGroup

The `AWS::Neptune::DBSubnetGroup` type creates an Amazon Neptune DB subnet group. Subnet groups must contain at least two subnets in two different Availability Zones in the same AWS Region.

Topics

- Syntax (p. 1831)
- Properties (p. 1831)
- Return Value (p. 1832)
- Example (p. 1832)
- See Also (p. 1833)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::Neptune::DBSubnetGroup",
   "Properties" : {
      "DBSubnetGroupDescription (p. 1831)" : String,
      "DBSubnetGroupName (p. 1832)" : String,
      "SubnetIds (p. 1832)" : [ String, ... ],
      "Tags" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: "AWS::Neptune::DBSubnetGroup"
Properties:
  DBSubnetGroupDescription (p. 1831): String
  DBSubnetGroupName (p. 1832): String
  SubnetIds (p. 1832):
    - String
  Tags:
    - Resource Tag
```

Properties

`DBSubnetGroupDescription`

The description for the DB subnet group.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`DBSubnetGroupName`

The name for the DB subnet group. This value is stored as a lowercase string.

Constraints: Must contain no more than 255 letters, numbers, periods, underscores, spaces, or hyphens. Must not be default.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SubnetIds`

The Amazon EC2 subnet IDs for the DB subnet group.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`Tags`

The tags that you want to attach to the Amazon RDS database subnet group.

Required: No

Type: A list of resource tags (p. 2258) in key-value format.

Update requires: No interruption (p. 120)

Return Value

Ref

When you pass the logical ID of an `AWS::Neptune::DBSubnetGroup` resource to the intrinsic `Ref` function, the function returns the name of the DB subnet group, such as `mystack-mydbsubnetgroup-0a12bc456789de0fg`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myDBSubnetGroup" : {
         "Type" : "AWS::Neptune::DBSubnetGroup",
         "Properties" : {
            "DBSubnetGroupDescription" : "description",
            "SubnetIds" : [ "subnet-7b5b4112", "subnet-7b5b4115" ],
            "Tags" : [ {"Key" : "String", "Value" : "String"} ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  myDBSubnetGroup:
    Type: "AWS::Neptune::DBSubnetGroup"
    Properties:
      DBSubnetGroupDescription: "description"
      SubnetIds:
        - "subnet-7b5b4112"
        - "subnet-7b5b4115"
      Tags:
        -
          Key: "String"
          Value: "String"
```

AWS OpsWorks Resource Types Reference

This section contains reference information for all AWS OpsWorks resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::OpsWorks::data-type-name
```

Topics

- AWS::OpsWorks::App (p. 1833)
- AWS::OpsWorks::ElasticLoadBalancerAttachment (p. 1839)
- AWS::OpsWorks::Instance (p. 1841)
- AWS::OpsWorks::Layer (p. 1852)
- AWS::OpsWorks::Stack (p. 1867)
- AWS::OpsWorks::UserProfile (p. 1882)
- AWS::OpsWorks::Volume (p. 1885)

AWS::OpsWorks::App

Defines an AWS OpsWorks app for an AWS OpsWorks stack. The app specifies the code that you want to run on an application server.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type": "AWS::OpsWorks::App",
  "Properties": {
```

```
    "AppSource" : Source,
    "Attributes" : { String:String, ... },
    "DataSources" : [ DataSource (p. 1837), ... ],
    "Description" : String,
    "Domains" :  [ String, ... ],
    "EnableSsl" : Boolean,
    "Environment" : [ Environment, ... ],
    "Name" : String,
    "Shortname" : String,
    "SslConfiguration" : { SslConfiguration },
    "StackId" : String,
    "Type" : String
  }
}
```

YAML

```
Type: "AWS::OpsWorks::App"
Properties:
  AppSource:
    Source
  Attributes:
    String: String
  Description: String
  DataSources:
    - DataSource (p. 1837)
  Domains:
    - String
  EnableSsl: Boolean
  Environment:
    - Environment
  Name: String
  Shortname: String
  SslConfiguration:
    SslConfiguration
  StackId: String
  Type: String
```

Properties

`AppSource`

The information required to retrieve an app from a repository.

Required: No

Type: AWS OpsWorks Source Type (p. 1881)

Update requires: No interruption (p. 120)

`Attributes`

One or more user-defined key-value pairs to be added to the app attributes bag.

Required: No

Type: A list of key-value pairs

Update requires: No interruption (p. 120)

`Description`

A description of the app.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DataSources`

A list of databases to associate with the AWS OpsWorks app.

Required: No

Type: List of AWS OpsWorks App DataSource (p. 1837)

Update requires: No interruption (p. 120)

`Domains`

The app virtual host settings, with multiple domains separated by commas. For example, `'www.example.com, example.com'`.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`EnableSsl`

Whether to enable SSL for this app.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Environment`

The environment variables to associate with the AWS OpsWorks app.

Required: No

Type: List of AWS OpsWorks App Environment (p. 1838)

Update requires: No interruption (p. 120)

`Name`

The name of the AWS OpsWorks app.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Shortname`

The app short name, which is used internally by AWS OpsWorks and by Chef recipes.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SslConfiguration`

The SSL configuration

Required: No

Type: AWS OpsWorks SslConfiguration Type (p. 1839)

Update requires: No interruption (p. 120)

`StackId`

The ID of the AWS OpsWorks stack to associate this app with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Type`

The app type. Each supported type is associated with a particular layer. For more information, see CreateApp in the *AWS OpsWorks Stacks API Reference*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myApp" }
```

For the AWS OpsWorks stack `myApp`, `Ref` returns the ID of the AWS OpsWorks app.

For more information about using the `Ref` function, see Ref (p. 2341).

Template Snippet

The following snippet creates an AWS OpsWorks app that uses a PHP application in a Git repository:

JSON

```
"myApp" : {
  "Type" : "AWS::OpsWorks::App",
  "Properties" : {
    "StackId" : {"Ref":"myStack"},
    "Type" : "php",
    "Name" : "myPHPapp",
    "AppSource" : {
      "Type" : "git",
      "Url" : "git://github.com/amazonwebservices/opsworks-demo-php-simple-app.git",
      "Revision" : "version1"
    }
```

```
  }
}
```

YAML

```
myApp:
  Type: "AWS::OpsWorks::App"
  Properties:
    StackId:
      Ref: "myStack"
    Type: "php"
    Name: "myPHPapp"
    AppSource:
      Type: "git"
      Url: "git://github.com/amazonwebservices/opsworks-demo-php-simple-app.git"
      Revision: "version1"
```

More Info

- AWS::OpsWorks::Stack (p. 1867)
- AWS::OpsWorks::Layer (p. 1852)
- AWS::OpsWorks::Instance (p. 1841)

AWS OpsWorks App DataSource

`DataSource` is a property of the AWS::OpsWorks::App (p. 1833) resource that specifies a database to associate with an AWS OpsWorks app.

Syntax

JSON

```
{
  "Arn" : String,
  "DatabaseName" : String,
  "Type" : String
}
```

YAML

```
Arn: String
DatabaseName: String
Type: String
```

Properties

`Arn`

The ARN of the data source.

Required: No

Type: String

`DatabaseName`

The name of the database.

Required: No

Type: String

`Type`

The type of the data source, such as `AutoSelectOpsworksMysqlInstance`, `OpsworksMysqlInstance`, or `RdsDbInstance`. For valid values, see the DataSource type in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

AWS OpsWorks App Environment

`Environment` is a property of the AWS::OpsWorks::App (p. 1833) resource that specifies the environment variable to associate with the AWS OpsWorks app.

Syntax

JSON

```
{
  "Key" : String,
  "Secure" : Boolean,
  "Value" : String
}
```

YAML

```
Key: String
Secure: Boolean
Value: String
```

Properties

`Key`

The name of the environment variable, which can consist of up to 64 characters. You can use upper and lowercase letters, numbers, and underscores (_), but the name must start with a letter or underscore.

Required: Yes

Type: String

`Secure`

Indicates whether the value of the environment variable is concealed, such as with a DescribeApps response. To conceal an environment variable's value, set the value to `true`.

Required: No

Type: Boolean

`Value`

The value of the environment variable, which can be empty. You can specify a value of up to 256 characters.

Required: Yes

Type: String

AWS OpsWorks SslConfiguration Type

Describes an SSL configuration for the AWS::OpsWorks::App (p. 1833) resource type.

Syntax

JSON

```
{
  "Certificate" : String,
  "Chain" : String,
  "PrivateKey" : String
}
```

YAML

```
Certificate: String
Chain: String
PrivateKey: String
```

Properties

`Certificate`

The contents of the certificate's `domain.crt` file.

Required: Yes

Type: String

`Chain`

An intermediate certificate authority key or client authentication.

Required: No

Type: String

`PrivateKey`

The private key; the contents of the certificate's `domain.kex` file.

Required: Yes

Type: String

AWS::OpsWorks::ElasticLoadBalancerAttachment

Attaches an Elastic Load Balancing load balancer to an AWS OpsWorks layer that you specify.

Topics

- Syntax (p. 1840)
- Properties (p. 1840)
- Template Snippet (p. 1840)

- See Also (p. 1841)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type": "AWS::OpsWorks::ElasticLoadBalancerAttachment",
  "Properties": {
    "ElasticLoadBalancerName" : String,
    "LayerId" : String
  }
}
```

YAML

```
Type: "AWS::OpsWorks::ElasticLoadBalancerAttachment"
Properties:
  ElasticLoadBalancerName: String
  LayerId: String
```

Properties

`ElasticLoadBalancerName`

Elastic Load Balancing load balancer name.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`LayerId`

The AWS OpsWorks layer ID that the Elastic Load Balancing load balancer will be attached to.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Template Snippet

The following snippet specifies a load balancer attachment to an AWS OpsWorks layer, both of which would be described elsewhere in the same template:

JSON

```
"ELBAttachment" : {
  "Type" : "AWS::OpsWorks::ElasticLoadBalancerAttachment",
    "Properties" : {
      "ElasticLoadBalancerName" : { "Ref" : "ELB" },
      "LayerId" : { "Ref" : "Layer" }
    }
```

```
}
```

YAML

```
ELBAttachment:
  Type: "AWS::OpsWorks::ElasticLoadBalancerAttachment"
  Properties:
    ElasticLoadBalancerName:
      Ref: "ELB"
    LayerId:
      Ref: "Layer"
```

See Also

- AWS::OpsWorks::Layer (p. 1852)

AWS::OpsWorks::Instance

Creates an Amazon Elastic Compute Cloud (Amazon EC2) instance for an AWS OpsWorks stack. Instances for AWS OpsWorks stacks handle the work of serving applications and balancing traffic, for example.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type": "AWS::OpsWorks::Instance",
  "Properties": {
    "AgentVersion" : String,
    "AmiId" : String,
    "Architecture" : String,
    "AutoScalingType" : String,
    "AvailabilityZone" : String,
    "BlockDeviceMappings" : [ BlockDeviceMapping (p. 1848), ... ],
    "EbsOptimized" : Boolean,
    "ElasticIps" : [ String, ... ],
    "Hostname" : String,
    "InstallUpdatesOnBoot" : Boolean,
    "InstanceType" : String,
    "LayerIds" :  [ String, ... ],
    "Os" : String,
    "RootDeviceType" : String,
    "SshKeyName" : String,
    "StackId" : String,
    "SubnetId" : String,
    "Tenancy" : String,
    "TimeBasedAutoScaling" : TimeBasedAutoScaling (p. 1850),
    "VirtualizationType" : String,
    "Volumes" : [ String, ... ]
  }
}
```

YAML

```
Type: "AWS::OpsWorks::Instance"
Properties:
  AgentVersion: String
```

```
  AmiId: String
  Architecture: String
  AutoScalingType: String
  AvailabilityZone: String
  BlockDeviceMappings:
  - BlockDeviceMapping (p. 1848)
  EbsOptimized: Boolean
  ElasticIps:
  - String
  Hostname: String
  InstallUpdatesOnBoot: Boolean
  InstanceType: String
  LayerIds:
  - String
  Os: String
  RootDeviceType: String
  SshKeyName: String
  StackId: String
  SubnetId: String
  Tenancy: String
  TimeBasedAutoScaling:
  TimeBasedAutoScaling (p. 1850)
  VirtualizationType: String
  Volumes:
  - String
```

Properties

`AgentVersion`

The version of the AWS OpsWorks agent that AWS OpsWorks installs on each instance. AWS OpsWorks sends commands to the agent to performs tasks on your instances, such as starting Chef runs. For valid values, see the `AgentVersion` parameter for the CreateInstance action in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`AmiId`

The ID of the custom Amazon Machine Image (AMI) to be used to create the instance. For more information about custom AMIs, see Using Custom AMIs in the *AWS OpsWorks User Guide*.

> **Note**
> If you specify this property, you must set the `Os` property to `Custom`.

Required: No

Type: String

Update requires: Updates are not supported.

`Architecture`

The instance architecture.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`AutoScalingType`

For scaling instances, the type of scaling. If you specify load-based scaling, do not specify a time-based scaling configuration. For valid values, see CreateInstance in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`AvailabilityZone`

The instance Availability Zone.

Required: No

Type: String

Update requires: Replacement (p. 121)

`BlockDeviceMappings`

A list of block devices that are mapped to the AWS OpsWorks instance. For more information, see the `BlockDeviceMappings` parameter for the CreateInstance action in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: List of AWS OpsWorks Instance BlockDeviceMapping (p. 1848)

Update requires: Replacement (p. 121)

`EbsOptimized`

Whether the instance is optimized for Amazon Elastic Block Store (Amazon EBS) I/O. If you specify an Amazon EBS-optimized instance type, AWS OpsWorks enables EBS optimization by default. For more information, see Amazon EBS–Optimized Instances in the *Amazon EC2 User Guide for Linux Instances*.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`ElasticIps`

A list of Elastic IP addresses to associate with the instance.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Hostname`

The name of the instance host.

Required: No

Type: String

Update requires: No interruption (p. 120)

`InstallUpdatesOnBoot`

Whether to install operating system and package updates when the instance boots.

Required: No

Type: Boolean

Update requires: Some interruptions (p. 121)

`InstanceType`

The instance type, which must be supported by AWS OpsWorks. For more information, see CreateInstance in the *AWS OpsWorks Stacks API Reference*.

If you specify an Amazon EBS-optimized instance type, AWS OpsWorks enables EBS optimization by default. For more information about Amazon EBS-optimized instance types, see Amazon EBS–Optimized Instances in the *Amazon EC2 User Guide for Linux Instances*.

Required: Yes

Type: String

Update requires: Some interruptions (p. 121)

`LayerIds`

The IDs of the AWS OpsWorks layers to associate with this instance.

Required: Yes

Type: List of String values

Update requires: Some interruptions (p. 121)

`Os`

The instance operating system. For more information, see CreateInstance in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`RootDeviceType`

The root device type of the instance.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SshKeyName`

The SSH key name of the instance.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`StackId`

The ID of the AWS OpsWorks stack that this instance will be associated with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SubnetId`

The ID of the instance's subnet. If the stack is running in a VPC, you can use this parameter to override the stack's default subnet ID value and direct AWS OpsWorks to launch the instance in a different subnet.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Tenancy`

The tenancy of the instance. For more information, see the `Tenancy` parameter for the CreateInstance action in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`TimeBasedAutoScaling`

The time-based scaling configuration for the instance.

Required: No

Type: AWS OpsWorks TimeBasedAutoScaling Type (p. 1850)

Update requires: Replacement (p. 121)

`VirtualizationType`

The instance's virtualization type, `paravirtual` or `hvm`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Volumes`

A list of AWS OpsWorks volume IDs to associate with the instance. For more information, see AWS::OpsWorks::Volume (p. 1885).

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myInstance1" }
```

For the AWS OpsWorks instance `myInstance1`, `Ref` returns the AWS OpsWorks instance ID.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

- `AvailabilityZone`

  The Availability Zone of the AWS OpsWorks instance, such as `us-east-2a`.
- `PrivateDnsName`

  The private DNS name of the AWS OpsWorks instance.
- `PrivateIp`

  The private IP address of the AWS OpsWorks instance, such as `192.0.2.0`.
- `PublicDnsName`

  The public DNS name of the AWS OpsWorks instance.
- `PublicIp`

  The public IP address of the AWS OpsWorks instance, such as `192.0.2.0`.

  > **Note**
  > Use this attribute only when the AWS OpsWorks instance is in an AWS OpsWorks layer that auto-assigns public IP addresses.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Create Basic AWS OpsWorks Instances

The following example creates two AWS OpsWorks instances that are associated with the `myStack` AWS OpsWorks stack and the `myLayer` AWS OpsWorks layer:

JSON

```
"myInstance1" : {
  "Type" : "AWS::OpsWorks::Instance",
  "Properties" : {
    "StackId" : {"Ref":"myStack"},
    "LayerIds" : [{"Ref":"myLayer"}],
    "InstanceType" : "m1.small"
  }
},
```

```
"myInstance2" : {
  "Type" : "AWS::OpsWorks::Instance",
  "Properties" : {
    "StackId" : {"Ref":"myStack"},
    "LayerIds" : [{"Ref":"myLayer"}],
    "InstanceType" : "m1.small"
  }
}
```

YAML

```
myInstance1:
  Type: "AWS::OpsWorks::Instance"
  Properties:
    StackId:
      Ref: "myStack"
    LayerIds:
      -
        Ref: "myLayer"
    InstanceType: "m1.small"
myInstance2:
  Type: "AWS::OpsWorks::Instance"
  Properties:
    StackId:
      Ref: "myStack"
    LayerIds:
      -
        Ref: "myLayer"
    InstanceType: "m1.small"
```

Define a Time-based Auto Scaling Instance

In the following example, the `DBInstance` instance is online for four hours from UTC 1200-1600 on Friday, Saturday, and Sunday. The instance is offline for all other times and days.

JSON

```
"DBInstance" : {
  "Type" : "AWS::OpsWorks::Instance",
  "Properties" : {
    "AutoScalingType" : "timer",
    "StackId" : {"Ref":"Stack"},
    "LayerIds" : [{"Ref":"DBLayer"}],
    "InstanceType" : "m1.small",
    "TimeBasedAutoScaling" : {
      "Friday" : { "12" : "on", "13" : "on", "14" : "on", "15" : "on" },
      "Saturday" : { "12" : "on", "13" : "on", "14" : "on", "15" : "on" },
      "Sunday" : { "12" : "on", "13" : "on", "14" : "on", "15" : "on" }
    }
  }
}
```

YAML

```
DBInstance:
  Type: "AWS::OpsWorks::Instance"
  Properties:
    AutoScalingType: "timer"
    StackId:
      Ref: "Stack"
    LayerIds:
```

```
      - Ref: "DBLayer"
    InstanceType: "m1.small"
    TimeBasedAutoScaling:
      Friday:
        12: "on"
        13: "on"
        14: "on"
        15: "on"
      Saturday:
        12: "on"
        13: "on"
        14: "on"
        15: "on"
      Sunday:
        12: "on"
        13: "on"
        14: "on"
        15: "on"
```

AWS OpsWorks Instance BlockDeviceMapping

`BlockDeviceMappings` is a property of the AWS::OpsWorks::Instance (p. 1841) resource that defines the block devices that are mapped to an AWS OpsWorks instance.

Syntax

JSON

```
{
  "DeviceName" : String,
  "Ebs" : EbsBlockDevice (p. 1849),
  "NoDevice" : String,
  "VirtualName" : String
}
```

YAML

```
DeviceName: String
Ebs:
EbsBlockDevice (p. 1849)
NoDevice: String
VirtualName: String
```

Properties

`DeviceName`

The name of the device that is exposed to the instance, such as `/dev/dsh` or `xvdh`. For the root device, you can use the explicit device name or you can set this parameter to `ROOT_DEVICE`. If you set the parameter to `ROOT_DEVICE`, AWS OpsWorks provides the correct device name.

Required: No

Type: String

`Ebs`

Configuration information about the Amazon Elastic Block Store (Amazon EBS) volume.

Required: Conditional You can specify either the `VirtualName` or `Ebs`, but not both.

Type: AWS OpsWorks Instance BlockDeviceMapping EbsBlockDevice (p. 1849)

`NoDevice`

Suppresses the device that is specified in the block device mapping of the AWS OpsWorks instance Amazon Machine Image (AMI).

Required: No

Type: String

`VirtualName`

The name of the virtual device. The name must be in the form `ephemeralX`, where *X* is a number equal to or greater than zero (0), for example, `ephemeral0`.

Required: Conditional You can specify either the `VirtualName` or `Ebs`, but not both.

Type: String

AWS OpsWorks Instance BlockDeviceMapping EbsBlockDevice

`EbsBlockDevice` is a property of the AWS OpsWorks Instance BlockDeviceMapping (p. 1848) property that defines a block device for an Amazon Elastic Block Store (Amazon EBS) volume.

Syntax

JSON

```
{
  "DeleteOnTermination" : Boolean,
  "Iops" : Integer,
  "SnapshotId" : String,
  "VolumeSize" : Integer,
  "VolumeType" : String
}
```

YAML

```
DeleteOnTermination: Boolean
Iops: Integer
SnapshotId: String
VolumeSize: Integer
VolumeType: String
```

Properties

`DeleteOnTermination`

Indicates whether to delete the volume when the instance is terminated.

Required: No

Type: Boolean

`Iops`

The number of I/O operations per second (IOPS) that the volume supports. For more information, see Iops for the `EbsBlockDevice` action in the *Amazon EC2 API Reference*.

Required: No

Type: Integer

`SnapshotId`

The snapshot ID of the volume that you want to use. If you specify both the `SnapshotId` and `VolumeSize` properties, `VolumeSize` must be equal to or greater than the size of the snapshot.

Required: No

Type: String

`VolumeSize`

The volume size, in Gibibytes (GiB). If you specify both the `SnapshotId` and `VolumeSize` properties, `VolumeSize` must be equal to or greater than the size of the snapshot. For more information about specifying volume size, see VolumeSize for the `EbsBlockDevice` action in the *Amazon EC2 API Reference*.

Required: No

Type: Integer

`VolumeType`

The volume type. For more information about specifying the volume type, see VolumeType for the `EbsBlockDevice` action in the *Amazon EC2 API Reference*.

Required: No

Type: String

AWS OpsWorks TimeBasedAutoScaling Type

Describes the automatic time-based scaling configuration for an AWS::OpsWorks::Instance (p. 1841) resource type. For more information, see SetTimeBasedAutoScaling in the *AWS OpsWorks Stacks API Reference*.

Syntax

JSON

```
{
  "Friday" : { Integer : String, ... },
  "Monday" : { Integer : String, ... },
  "Saturday" : { Integer : String, ... },
  "Sunday" : { Integer : String, ... },
  "Thursday" : { Integer : String, ... },
  "Tuesday" : { Integer : String, ... },
  "Wednesday" : { Integer : String, ... }
}
```

YAML

```
Friday:
```

```
  Integer: String
Monday:
  Integer: String
Saturday:
  Integer: String
Sunday:
  Integer: String
Thursday:
  Integer: String
Tuesday:
  Integer: String
Wednesday:
  Integer: String
```

Properties

For each day of the week, the schedule consists of a set of key–value pairs, where the key is the time period (a UTC hour) of `0` – `23` and the value indicates whether the instance should be online (`on`) or offline (`off`) for the specified period.

`Friday`

The schedule for Friday.

Required: No

Type: String to string map

`Monday`

The schedule for Monday.

Required: No

Type: String to string map

`Saturday`

The schedule for Saturday.

Required: No

Type: String to string map

`Sunday`

The schedule for Sunday.

Required: No

Type: String to string map

`Thursday`

The schedule for Thursday.

Required: No

Type: String to string map

`Tuesday`

The schedule for Tuesday.

Required: No

Type: String to string map

`Wednesday`

The schedule for Wednesday.

Required: No

Type: String to string map

AWS::OpsWorks::Layer

Creates an AWS OpsWorks layer. A layer defines, for example, which packages and applications are installed and how they are configured.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type": "AWS::OpsWorks::Layer",
  "Properties": {
    "Attributes" : { String:String },
    "AutoAssignElasticIps" : Boolean,
    "AutoAssignPublicIps" : Boolean,
    "CustomInstanceProfileArn" : String,
    "CustomJson" : JSON object,
    "CustomRecipes" : Recipes,
    "CustomSecurityGroupIds" :  [ String, ... ],
    "EnableAutoHealing" : Boolean,
    "InstallUpdatesOnBoot" : Boolean,
    "LifecycleEventConfiguration" : LifeCycleEventConfiguration,
    "LoadBasedAutoScaling" : LoadBasedAutoScaling,
    "Name" : String,
    "Packages" : [ String, ... ],
    "Shortname" : String,
    "StackId" : String,
    "Tags" : [ Tags (p. 2258), ... ],
    "Type" : String,
    "VolumeConfigurations" : [ VolumeConfiguration, ... ]
  }
}
```

YAML

```
Type: "AWS::OpsWorks::Layer"
Properties:
  Attributes:
    String:String
  AutoAssignElasticIps: Boolean
  AutoAssignPublicIps: Boolean
  CustomInstanceProfileArn: String
  CustomRecipes:
    Recipes
  CustomJson:
    JSON object
  CustomSecurityGroupIds:
    - String
  EnableAutoHealing: Boolean
```

```
  InstallUpdatesOnBoot: Boolean
  LifecycleEventConfiguration:
    LifeCycleEventConfiguration
  LoadBasedAutoScaling:
    LoadBasedAutoScaling
  Name: String
  Packages:
    - String
  Shortname: String
  StackId: String
  Tags:
  - Tags (p. 2258)
  Type: String
  VolumeConfigurations:
    - VolumeConfiguration
```

Properties

`Attributes`

One or more user-defined key-value pairs to be added to the stack attributes bag.

Required: No

Type: A list of key-value pairs

Update requires: No interruption (p. 120)

`AutoAssignElasticIps`

Whether to automatically assign an Elastic IP address to Amazon EC2 instances in this layer.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

`AutoAssignPublicIps`

For AWS OpsWorks stacks that are running in a VPC, whether to automatically assign a public IP address to Amazon EC2 instances in this layer.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

`CustomInstanceProfileArn`

The Amazon Resource Name (ARN) of an IAM instance profile that is to be used for the Amazon EC2 instances in this layer.

Required: No

Type: String

Update requires: No interruption (p. 120)

`CustomJson`

A custom stack configuration and deployment attributes that AWS OpsWorks installs on the layer's instances. For more information, see the `CustomJson` parameter for the CreateLayer action in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: JSON object

`CustomRecipes`

Custom event recipes for this layer.

Required: No

Type: AWS OpsWorks Recipes Type (p. 1864)

Update requires: No interruption (p. 120)

`CustomSecurityGroupIds`

Custom security group IDs for this layer.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`EnableAutoHealing`

Whether to automatically heal Amazon EC2 instances that have become disconnected or timed out.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

`InstallUpdatesOnBoot`

Whether to install operating system and package updates when the instance boots.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`LifecycleEventConfiguration`

The lifecycle events for the AWS OpsWorks layer.

Required: No

Type: AWS OpsWorks Layer LifeCycleConfiguration (p. 1863)

Update requires: No interruption (p. 120)

`LoadBasedAutoScaling`

The load-based scaling configuration for the AWS OpsWorks layer.

Required: No

Type: AWS OpsWorks LoadBasedAutoScaling Type (p. 1863)

Update requires: No interruption (p. 120)

`Name`

The AWS OpsWorks layer name.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Packages`

The packages for this layer.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`Shortname`

The layer short name, which is used internally by AWS OpsWorks and by Chef recipes. The short name is also used as the name for the directory where your app files are installed.

The name can have a maximum of 200 characters, which are limited to the alphanumeric characters, '-', '_', and '.'.

> **Important**
> If you update a property that requires the layer to be replaced, you must specify a new short name. You cannot have multiple layers with the same short name.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`StackId`

The ID of the AWS OpsWorks stack that this layer will be associated with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this AWS OpsWorks layer. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`Type`

The layer type. A stack cannot have more than one layer of the same type, except for the `custom` type. You can have any number of `custom` types. For more information, see CreateLayer in the *AWS OpsWorks Stacks API Reference*.

> **Important**
> If you update a property that requires the layer to be replaced, you must specify a new type unless you have a `custom` type. You can have any number of `custom` types.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`VolumeConfigurations`

Describes the Amazon EBS volumes for this layer.

Required: No

Type: A list of AWS OpsWorks VolumeConfiguration Type (p. 1866)

Update requires: Some interruptions (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myLayer" }
```

For the AWS OpsWorks layer `myLayer`, `Ref` returns the AWS OpsWorks layer ID.

For more information about using the `Ref` function, see Ref (p. 2341).

Template Examples

AWS OpsWorks PHP Layer

The following snippet creates an AWS OpsWorks PHP layer that is associated with the `myStack` AWS OpsWorks stack. The layer is dependent on the `myApp` AWS OpsWorks application.

JSON

```
"myLayer": {
  "Type": "AWS::OpsWorks::Layer",
  "DependsOn": "myApp",
  "Properties": {
    "StackId": {"Ref": "myStack"},
    "Type": "php-app",
    "Shortname" : "php-app",
    "EnableAutoHealing" : "true",
    "AutoAssignElasticIps" : "false",
    "AutoAssignPublicIps" : "true",
    "Name": "MyPHPApp"
  }
}
```

YAML

```
myLayer:
  Type: "AWS::OpsWorks::Layer"
  DependsOn: "myApp"
  Properties:
    StackId:
      Ref: "myStack"
    Type: "php-app"
    Shortname: "php-app"
```

```
    EnableAutoHealing: "true"
    AutoAssignElasticIps: "false"
    AutoAssignPublicIps: "true"
    Name: "MyPHPApp"
```

Load-based Auto Scaling Layer

The following snippet creates a load-based automatic scaling AWS OpsWorks PHP layer that is associated with the `myStack` AWS OpsWorks stack.

JSON

```
"myLayer": {
  "Type": "AWS::OpsWorks::Layer",
  "DependsOn": "myApp",
  "Properties": {
    "StackId": {"Ref": "myStack"},
    "Type": "php-app",
    "Shortname" : "php-app",
    "EnableAutoHealing" : "true",
    "AutoAssignElasticIps" : "false",
    "AutoAssignPublicIps" : "true",
    "Name": "MyPHPApp",
    "LoadBasedAutoScaling" : {
      "Enable" : "true",
      "UpScaling" : {
        "InstanceCount" : 1,
        "ThresholdsWaitTime" : 1,
        "IgnoreMetricsTime" : 1,
        "CpuThreshold" : 70.0,
        "MemoryThreshold" : 30.0,
        "LoadThreshold" : 0.7
      },
      "DownScaling" : {
        "InstanceCount" : 1,
        "ThresholdsWaitTime" : 1,
        "IgnoreMetricsTime" : 1,
        "CpuThreshold" : 30.0,
        "MemoryThreshold" : 70.0,
        "LoadThreshold" : 0.3
      }
    }
  }
}
```

YAML

```
myLayer:
  Type: "AWS::OpsWorks::Layer"
  DependsOn: "myApp"
  Properties:
    StackId:
      Ref: "myStack"
    Type: "php-app"
    Shortname: "php-app"
    EnableAutoHealing: "true"
    AutoAssignElasticIps: "false"
    AutoAssignPublicIps: "true"
    Name: "MyPHPApp"
    LoadBasedAutoScaling:
      Enable: "true"
      UpScaling:
        InstanceCount: 1
```

```
        ThresholdsWaitTime: 1
        IgnoreMetricsTime: 1
        CpuThreshold: 70
        MemoryThreshold: 30
        LoadThreshold: 0.7
      DownScaling:
        InstanceCount: 1
        ThresholdsWaitTime: 1
        IgnoreMetricsTime: 1
        CpuThreshold: 30
        MemoryThreshold: 70
        LoadThreshold: 0.3
```

Specify tags for layers and stacks

The following complete template example specifies tags for an AWS OpsWorks layer and stack that reference parameter values.

JSON

```
{
    "Resources": {
        "ServiceRole": {
            "Type": "AWS::IAM::Role",
            "Properties": {
                "AssumeRolePolicyDocument": {
                    "Statement": [
                        {
                            "Effect": "Allow",
                            "Principal": {
                                "Service": [
                                    {
                                        "Ref": "OpsServicePrincipal"
                                    }
                                ]
                            },
                            "Action": [
                                "sts:AssumeRole"
                            ]
                        }
                    ]
                },
                "Path": "/",
                "Policies": [
                    {
                        "PolicyName": "opsworks-service",
                        "PolicyDocument": {
                            "Statement": [
                                {
                                    "Effect": "Allow",
                                    "Action": [
                                        "ec2:*",
                                        "iam:PassRole",
                                        "cloudwatch:GetMetricStatistics",
                                        "elasticloadbalancing:*"
                                    ],
                                    "Resource": "*"
                                }
                            ]
                        }
                    }
                ]
            }
        },
```

```
        "OpsWorksEC2Role": {
            "Type": "AWS::IAM::Role",
            "Properties": {
                "AssumeRolePolicyDocument": {
                    "Statement": [
                        {
                            "Effect": "Allow",
                            "Principal": {
                                "Service": [
                                    {
                                        "Ref": "Ec2ServicePrincipal"
                                    }
                                ]
                            },
                            "Action": [
                                "sts:AssumeRole"
                            ]
                        }
                    ]
                },
                "Path": "/"
            }
        },
        "InstanceRole": {
            "Type": "AWS::IAM::InstanceProfile",
            "Properties": {
                "Path": "/",
                "Roles": [
                    {
                        "Ref": "OpsWorksEC2Role"
                    }
                ]
            }
        },
        "myStack": {
            "Type": "AWS::OpsWorks::Stack",
            "Properties": {
                "Name": "TestStack",
                "ServiceRoleArn": {
                    "Fn::GetAtt": [
                        "ServiceRole",
                        "Arn"
                    ]
                },
                "DefaultInstanceProfileArn": {
                    "Fn::GetAtt": [
                        "InstanceRole",
                        "Arn"
                    ]
                },
                "Tags": [
                    {
                        "Key": {
                            "Ref": "StackKey"
                        },
                        "Value": {
                            "Ref": "StackValue"
                        }
                    }
                ]
            }
        },
        "myLayer": {
            "Type": "AWS::OpsWorks::Layer",
            "Properties": {
                "EnableAutoHealing": "true",
```

```
                "AutoAssignElasticIps": "false",

AWS OpsWorks AutoScalingThresholds Type

Describes the scaling thresholds for the AWS OpsWorks LoadBasedAutoScaling Type (p. 1863) property. For more information, see AutoScalingThresholds in the *AWS OpsWorks Stacks API Reference*.

Syntax

JSON

```
{
  "CpuThreshold" : Number,
  "IgnoreMetricsTime" : Integer,
  "InstanceCount" : Integer,
  "LoadThreshold" : Number,
  "MemoryThreshold" : Number,
  "ThresholdsWaitTime" : Integer
}
```

YAML

```
CpuThreshold: Number
IgnoreMetricsTime: Integer
InstanceCount: Integer
LoadThreshold: Number
MemoryThreshold: Number
ThresholdsWaitTime: Integer
```

Properties

`CpuThreshold`

The percentage of CPU utilization that triggers the starting or stopping of instances (scaling).

Required: No

Type: Number

`IgnoreMetricsTime`

The amount of time (in minutes) after a scaling event occurs that AWS OpsWorks should ignore metrics and not start any additional scaling events.

Required: No

Type: Integer

`InstanceCount`

The number of instances to add or remove when the load exceeds a threshold.

Required: No

Type: Integer

`LoadThreshold`

The degree of system load that triggers the starting or stopping of instances (scaling). For more information about how load is computed, see Load (computing).

Required: No

Type: Number

`MemoryThreshold`

The percentage of memory consumption that triggers the starting or stopping of instances (scaling).

Required: No

Type: Number

`ThresholdsWaitTime`

The amount of time, in minutes, that the load must exceed a threshold before instances are added or removed.

Required: No

Type: Integer

AWS OpsWorks Layer LifeCycleConfiguration

`LifeCycleConfiguration` is property of the AWS::OpsWorks::Layer (p. 1852) resource that specifies the lifecycle event configuration for the layer.

Syntax

JSON

```
{
  "ShutdownEventConfiguration" : ShutdownEventConfiguration
}
```

YAML

```
ShutdownEventConfiguration:
  ShutdownEventConfiguration
```

Properties

`ShutdownEventConfiguration`

Specifies the shutdown event configuration for a layer.

Required: No

Type: AWS OpsWorks Layer LifeCycleConfiguration ShutdownEventConfiguration (p. 1866)

AWS OpsWorks LoadBasedAutoScaling Type

Describes the load-based automatic scaling configuration for an AWS::OpsWorks::Layer (p. 1852) resource type. For more information, see SetLoadBasedAutoScaling in the *AWS OpsWorks Stacks API Reference*.

Syntax

JSON

```
{
  "DownScaling" : { AutoScalingThresholds },
  "Enable" : Boolean,
  "UpScaling" : { AutoScalingThresholds }
}
```

YAML

```
DownScaling:
  AutoScalingThresholds
Enable: Boolean
UpScaling:
  AutoScalingThresholds
```

Properties

`DownScaling`

The threshold below which the instances are scaled down (stopped). If the load falls below this threshold for a specified amount of time, AWS OpsWorks stops a specified number of instances.

Required: No

Type: AWS OpsWorks AutoScalingThresholds Type (p. 1862)

`Enable`

Whether to enable automatic load-based scaling for the layer.

Required: No

Type: Boolean

`UpScaling`

The threshold above which the instances are scaled up (added). If the load exceeds this thresholds for a specified amount of time, AWS OpsWorks starts a specified number of instances.

Required: No

Type: AWS OpsWorks AutoScalingThresholds Type (p. 1862)

AWS OpsWorks Recipes Type

Describes custom event recipes for the AWS::OpsWorks::Layer (p. 1852) resource type that AWS OpsWorks runs after the standard event recipes. For more information, see AWS OpsWorks Lifecycle Events in the *AWS OpsWorks User Guide*.

Syntax

JSON

```
{
  "Configure" : [ String, ... ],
  "Deploy" : [ String, ... ],
```

```
  "Setup" : [ String, ... ],
  "Shutdown" : [ String, ... ],
  "Undeploy" : [ String, ... ]
}
```

YAML

```
Configure:
  - String
Deploy:
  - String
Setup:
  - String
Shutdown:
  - String
Undeploy:
  - String
```

Properties

`Configure`

Custom recipe names to be run following a Configure event. The event occurs on all of the stack's instances when an instance enters or leaves the online state.

Required: No

Type: List of String values

`Deploy`

Custom recipe names to be run following a Deploy event. The event occurs when you run a `deploy` command, typically to deploy an application to a set of application server instances.

Required: No

Type: List of String values

`Setup`

Custom recipe names to be run following a Setup event. This event occurs on a new instance after it successfully boots.

Required: No

Type: List of String values

`Shutdown`

Custom recipe names to be run following a Shutdown event. This event occurs after you direct AWS OpsWorks to shut an instance down before the associated Amazon EC2 instance is actually terminated.

Required: No

Type: List of String values

`Undeploy`

Custom recipe names to be run following a Undeploy event. This event occurs when you delete an app or run an `undeploy` command to remove an app from a set of application server instances.

Required: No

Type: List of String values

AWS OpsWorks Layer LifeCycleConfiguration ShutdownEventConfiguration

`ShutdownEventConfiguration` is a property of the AWS OpsWorks Layer LifeCycleConfiguration (p. 1863) property that specifies the shutdown event configuration for a lifecycle event.

Syntax

JSON

```
{
  "DelayUntilElbConnectionsDrained" : Boolean,
  "ExecutionTimeout" : Integer
}
```

YAML

```
DelayUntilElbConnectionsDrained: Boolean
ExecutionTimeout: Integer
```

Properties

`DelayUntilElbConnectionsDrained`

Indicates whether to wait for connections to drain from the Elastic Load Balancing load balancers.

Required: No

Type: Boolean

`ExecutionTimeout`

The time, in seconds, that AWS OpsWorks waits after a shutdown event has been triggered before shutting down an instance.

Required: No

Type: Integer

AWS OpsWorks VolumeConfiguration Type

Describes the Amazon EBS volumes for the AWS::OpsWorks::Layer (p. 1852) resource type.

Syntax

JSON

```
{
  "Iops" : Integer,
  "MountPoint" : String,
  "NumberOfDisks" : Integer,
  "RaidLevel" : Integer,
  "Size" : Integer,
  "VolumeType" : String
}
```

YAML

```yaml
Iops: Integer
MountPoint: String
NumberOfDisks: Integer
RaidLevel: Integer
Size: Integer
VolumeType: String
```

Properties

`Iops`

The number of I/O operations per second (IOPS) to provision for the volume.

Required: Conditional. If you specify `io1` for the volume type, you must specify this property.

Type: Integer

`MountPoint`

The volume mount point, such as `/dev/sdh`.

Required: Yes

Type: String

`NumberOfDisks`

The number of disks in the volume.

Required: Yes

Type: Integer

`RaidLevel`

The volume RAID level.

Required: No

Type: Integer

`Size`

The volume size.

Required: Yes

Type: Integer

`VolumeType`

The type of volume, such as magnetic or SSD. For valid values, see VolumeConfiguration in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

AWS::OpsWorks::Stack

Creates an AWS OpsWorks stack. An AWS OpsWorks stack represents a set of instances that you want to manage collectively, typically because they have a common purpose such as serving PHP applications.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::OpsWorks::Stack",
  "Properties" : {
    "AgentVersion" : String,
    "Attributes" : { String:String, ... },
    "ChefConfiguration" : { ChefConfiguration },
    "CloneAppIds" : [ String, ... ],
    "ClonePermissions" : Boolean,
    "ConfigurationManager" : { StackConfigurationManager },
    "CustomCookbooksSource" : { Source },
    "CustomJson" : JSON,
    "DefaultAvailabilityZone" : String,
    "DefaultInstanceProfileArn" : String,
    "DefaultOs" : String,
    "DefaultRootDeviceType" : String,
    "DefaultSshKeyName" : String,
    "DefaultSubnetId" : String,
    "EcsClusterArn" : String,
    "ElasticIps" : [ ElasticIp (p. 1879), ... ],
    "HostnameTheme" : String,
    "Name" : String,
    "RdsDbInstances" : [ RdsDbInstance (p. 1879), ... ],
    "ServiceRoleArn" : String,
    "SourceStackId" : String,
    "Tags" : [ Tags (p. 2258), ... ],
    "UseCustomCookbooks" : Boolean,
    "UseOpsworksSecurityGroups" : Boolean,
    "VpcId" : String
  }
}
```

YAML

```
Type: "AWS::OpsWorks::Stack"
Properties:
  AgentVersion: String
  Attributes:
    String:String
  ChefConfiguration:
    ChefConfiguration
  CloneAppIds:
  - String
  ClonePermissions: Boolean
  ConfigurationManager:
    StackConfigurationManager
  CustomCookbooksSource:
    Source
  CustomJson: JSON
  DefaultAvailabilityZone: String
  DefaultInstanceProfileArn: String
  DefaultOs: String
  DefaultRootDeviceType: String
  DefaultSshKeyName: String
  DefaultSubnetId: String
  EcsClusterArn: String
  ElasticIps:
  - ElasticIp (p. 1879)
```

```
  HostnameTheme: String
  Name: String
  RdsDbInstances:
  - RdsDbInstance (p. 1879)
  ServiceRoleArn: String
  SourceStackId: String
  Tags:
  - Tags (p. 2258)
  UseCustomCookbooks: Boolean
  UseOpsworksSecurityGroups: Boolean
  VpcId: String
```

Properties

`AgentVersion`

The AWS OpsWorks agent version that you want to use. The agent communicates with the service and handles tasks such as initiating Chef runs in response to lifecycle events. For valid values, see the AgentVersion parameter for the `CreateStack` action in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Attributes`

One or more user-defined key-value pairs to be added to the stack attributes bag.

Required: No

Type: A list of key-value pairs

Update requires: No interruption (p. 120)

`ChefConfiguration`

Describes the Chef configuration. For more information, see the CreateStack ChefConfiguration parameter in the *AWS OpsWorks Stacks API Reference*.

> **Note**
> To enable Berkshelf, you must select a Chef version in the `ConfigurationManager` property that supports Berkshelf.

Required: No

Type: AWS OpsWorks ChefConfiguration Type (p. 1878)

Update requires: No interruption (p. 120)

`CloneAppIds`

If you're cloning an AWS OpsWorks stack, a list of AWS OpsWorks application stack IDs from the source stack to include in the cloned stack.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`ClonePermissions`

If you're cloning an AWS OpsWorks stack, indicates whether to clone the source stack's permissions.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`ConfigurationManager`

Describes the configuration manager. When you create a stack, you use the configuration manager to specify the Chef version. For supported Chef versions, see the CreateStack ConfigurationManager parameter in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: AWS OpsWorks StackConfigurationManager Type (p. 1880)

Update requires: No interruption (p. 120)

`CustomCookbooksSource`

Contains the information required to retrieve a cookbook from a repository.

Required: No

Type: AWS OpsWorks Source Type (p. 1881)

Update requires: No interruption (p. 120)

`CustomJson`

A user-defined custom JSON object. The custom JSON is used to override the corresponding default stack configuration JSON values. For more information, see CreateStack in the *AWS OpsWorks Stacks API Reference*.

> **Important**
> AWS CloudFormation submits all JSON attributes as strings, including any Boolean or number attributes. If you have recipes that expect booleans or numbers, you must modify the recipes to accept strings and to interpret those strings as booleans or numbers.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`DefaultAvailabilityZone`

The stack's default Availability Zone, which must be in the specified region.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DefaultInstanceProfileArn`

The Amazon Resource Name (ARN) of an IAM instance profile that is the default profile for all of the stack's Amazon EC2 instances.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`DefaultOs`

The stack's default operating system. For more information, see CreateStack in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DefaultRootDeviceType`

The default root device type. This value is used by default for all instances in the stack, but you can override it when you create an instance. For more information, see CreateStack in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DefaultSshKeyName`

A default SSH key for the stack instances. You can override this value when you create or update an instance.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DefaultSubnetId`

The stack's default subnet ID. All instances are launched into this subnet unless you specify another subnet ID when you create the instance.

Required: Conditional. If you specify the `VpcId` property, you must specify this property.

Type: String

Update requires: No interruption (p. 120)

`EcsClusterArn`

The Amazon Resource Name (ARN) of the Amazon Elastic Container Service (Amazon ECS) cluster to register with the AWS OpsWorks stack.

> **Note**
> If you specify a cluster that's registered with another AWS OpsWorks stack, AWS CloudFormation deregisters the existing association before registering the cluster.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ElasticIps`

A list of Elastic IP addresses to register with the AWS OpsWorks stack.

> **Note**
> If you specify an IP address that's registered with another AWS OpsWorks stack, AWS CloudFormation deregisters the existing association before registering the IP address.

Required: No

Type: List of AWS OpsWorks Stack ElasticIp (p. 1879)

Update requires: No interruption (p. 120)

`HostnameTheme`

The stack's host name theme, with spaces replaced by underscores. The theme is used to generate host names for the stack's instances. For more information, see CreateStack in the *AWS OpsWorks Stacks API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the AWS OpsWorks stack.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RdsDbInstances`

The Amazon Relational Database Service (Amazon RDS) DB instance to register with the AWS OpsWorks stack.

> **Note**
> If you specify a DB instance that's registered with another AWS OpsWorks stack, AWS CloudFormation deregisters the existing association before registering the DB instance.

Required: No

Type: List of AWS OpsWorks Stack RdsDbInstance (p. 1879)

Update requires: No interruption (p. 120)

`ServiceRoleArn`

The AWS Identity and Access Management (IAM) role that AWS OpsWorks uses to work with AWS resources on your behalf. You must specify an Amazon Resource Name (ARN) for an existing IAM role.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SourceStackId`

If you're cloning an AWS OpsWorks stack, the stack ID of the source AWS OpsWorks stack to clone.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this AWS OpsWorks stack. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`UseCustomCookbooks`

Whether the stack uses custom cookbooks.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`UseOpsworksSecurityGroups`

Whether to associate the AWS OpsWorks built-in security groups with the stack's layers.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`VpcId`

The ID of the VPC that the stack is to be launched into, which must be in the specified region. All instances are launched into this VPC. If you specify this property, you must specify the `DefaultSubnetId` property.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myStack" }
```

For the AWS OpsWorks stack `myStack`, `Ref` returns the AWS OpsWorks stack ID.

For more information about using the `Ref` function, see Ref (p. 2341).

Template Examples

The following snippet creates an AWS OpsWorks stack that uses the default service role and Amazon EC2 role, which are created after you use AWS OpsWorks for the first time:

JSON

```
"myStack" : {
  "Type" : "AWS::OpsWorks::Stack",
  "Properties" : {
    "Name" : {"Ref":"OpsWorksStackName"},
    "ServiceRoleArn" : { "Fn::Join": ["", ["arn:aws:iam::", {"Ref":"AWS::AccountId"},
 ":role/aws-opsworks-service-role"]] },
    "DefaultInstanceProfileArn" : { "Fn::Join": ["", ["arn:aws:iam::",
 {"Ref":"AWS::AccountId"}, ":instance-profile/aws-opsworks-ec2-role"]] },
    "DefaultSshKeyName" : {"Ref":"KeyName"}
  }
}
```

YAML

```
myStack:
  Type: "AWS::OpsWorks::Stack"
  Properties:
    Name:
      Ref: "OpsWorksStackName"
    ServiceRoleArn:
      Fn::Join:
        - ""
        -
          - "arn:aws:iam::"
          -
            Ref: "AWS::AccountId"
          - ":role/aws-opsworks-service-role"
    DefaultInstanceProfileArn:
      Fn::Join:
        - ""
        -
          - "arn:aws:iam::"
          -
            Ref: "AWS::AccountId"
          - ":instance-profile/aws-opsworks-ec2-role"
    DefaultSshKeyName:
      Ref: "KeyName"
```

Specify tags for layers and stacks

The following complete template example specifies tags for an AWS OpsWorks layer and stack that reference parameter values.

JSON

```
{
    "Resources": {
        "ServiceRole": {
            "Type": "AWS::IAM::Role",
            "Properties": {
                "AssumeRolePolicyDocument": {
                    "Statement": [
                        {
                            "Effect": "Allow",
                            "Principal": {
                                "Service": [
                                    {
                                        "Ref": "OpsServicePrincipal"
                                    }
                                ]
```

```
                        },
                        "Action": [
                            "sts:AssumeRole"
                        ]
                    }
                ]
            },
            "Path": "/",
            "Policies": [
                {
                    "PolicyName": "opsworks-service",
                    "PolicyDocument": {
                        "Statement": [
                            {
                                "Effect": "Allow",
                                "Action": [

Additional Information

- For a complete sample AWS OpsWorks template, see AWS OpsWorks Template Snippets (p. 411).
- AWS::OpsWorks::Layer (p. 1852)
- AWS::OpsWorks::App (p. 1833)
- AWS::OpsWorks::Instance (p. 1841)

AWS OpsWorks ChefConfiguration Type

Describes the Chef configuration for the AWS::OpsWorks::Stack (p. 1867) resource type. For more information, see ChefConfiguration in the *AWS OpsWorks Stacks API Reference*.

Syntax

JSON

```
{
  "BerkshelfVersion" : String,
  "ManageBerkshelf" : Boolean
}
```

YAML

```
BerkshelfVersion: String
ManageBerkshelf: Boolean
```

Properties

`BerkshelfVersion`

The Berkshelf version.

Required: No

Type: String

`ManageBerkshelf`

Whether to enable Berkshelf.

Required: No

Type: Boolean

AWS OpsWorks Stack ElasticIp

`ElasticIps` is a property of the AWS::OpsWorks::Stack (p. 1867) resource that registers an Elastic IP address with an AWS OpsWorks stack.

Syntax

JSON

```
{
  "Ip" : String,
  "Name" : String
}
```

YAML

```
Ip: String
Name: String
```

Properties

`Ip`

The Elastic IP address.

Required: Yes

Type: String

`Name`

A name for the Elastic IP address.

Required: No

Type: String

AWS OpsWorks Stack RdsDbInstance

`RdsDbInstance` is a property of the AWS::OpsWorks::Stack (p. 1867) resource that registers an Amazon Relational Database Service (Amazon RDS) DB instance with an AWS OpsWorks stack.

Syntax

JSON

```
{
  "DbPassword" : String,
  "DbUser" : String,
```

```
  "RdsDbInstanceArn" : String
}
```

YAML

```
DbPassword: String
DbUser: String
RdsDbInstanceArn: String
```

Properties

`DbPassword`

The password of the registered database.

Required: Yes

Type: String

`DbUser`

The master user name of the registered database.

Required: Yes

Type: String

`RdsDbInstanceArn`

The Amazon Resource Name (ARN) of the Amazon RDS DB instance to register with the AWS OpsWorks stack.

Required: Yes

Type: String

AWS OpsWorks StackConfigurationManager Type

Describes the stack configuration manager for the AWS::OpsWorks::Stack (p. 1867) resource type. For more information, see StackConfigurationManager in the *AWS OpsWorks Stacks API Reference*.

Syntax

JSON

```
{
  "Name" : String,
  "Version" : String
}
```

YAML

```
Name: String
Version: String
```

Properties

`Name`

The name of the configuration manager.

Required: No

Type: String

`Version`

The Chef version.

Required: No

Type: String

AWS OpsWorks Source Type

Describes the information required to retrieve a cookbook or app from a repository for the AWS::OpsWorks::Stack (p. 1867) or AWS::OpsWorks::App (p. 1833) resource types.

For more information and valid values, see Source in the *AWS OpsWorks Stacks API Reference*.

Syntax

JSON

```
{
  "Password" : String,
  "Revision" : String,
  "SshKey" : String,
  "Type" : String,
  "Url" : String,
  "Username" : String
}
```

YAML

```
Password: String
Revision: String
SshKey: String
Type: String
Url: String
Username: String
```

Properties

`Password`

This parameter depends on the repository type. For Amazon S3 bundles, set `Password` to the appropriate IAM secret access key. For HTTP bundles, Git repositories, and Subversion repositories, set `Password` to the appropriate password.

Required: No

Type: String

`Revision`

The application's version. With AWS OpsWorks, you can deploy new versions of an application. One of the simplest approaches is to have branches or revisions in your repository that represent different versions that can potentially be deployed.

Required: No

Type: String

`SshKey`

The repository's SSH key. For more information, see Using Git Repository SSH Keys in the *AWS OpsWorks User Guide*.

To pass in an SSH key as a parameter, see the following example:

```
"Parameters" : {
  "GitSSHKey" : {
    "Description" : "Change SSH key newlines to commas.",
    "Type" : "CommaDelimitedList",
    "NoEcho" : "true"
  },

...

  "CustomCookbooksSource": {
    "Revision" : { "Ref": "GitRevision"},
    "SshKey" : { "Fn::Join" : [ "\n", { "Ref": "GitSSHKey"} ] },
    "Type": "git",
    "Url": { "Ref": "GitURL"}
  }

...
```

Required: No

Type: String

`Type`

The repository type.

Required: No

Type: String

`Url`

The source URL.

Required: No

Type: String

`Username`

This parameter depends on the repository type. For Amazon S3 bundles, set `Username` to the appropriate IAM access key ID. For HTTP bundles, Git repositories, and Subversion repositories, set `Username` to the appropriate user name.

Required: No

Type: String

AWS::OpsWorks::UserProfile

The `AWS::OpsWorks::UserProfile` resource configures SSH access for users who require access to instances in an AWS OpsWorks stack.

Topics

- Syntax (p. 1883)
- Properties (p. 1883)
- Return Value (p. 1884)
- Example (p. 1884)

Syntax

JSON

```
{
  "Type" : "AWS::OpsWorks::UserProfile",
  "Properties" : {
    "AllowSelfManagement" : Boolean,
    "IamUserArn" : String,
    "SshPublicKey" : String,
    "SshUsername" : String
  }
}
```

YAML

```
Type: "AWS::OpsWorks::UserProfile"
Properties:
  AllowSelfManagement: Boolean
  IamUserArn: String
  SshPublicKey: String
  SshUsername: String
```

Properties

`AllowSelfManagement`

Indicates whether users can use the AWS OpsWorks **My Settings** page to specify their own SSH public key. For more information, see Setting an IAM User's Public SSH Key in the *AWS OpsWorks User Guide*.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`IamUserArn`

The Amazon Resource Name (ARN) of the AWS Identity and Access Management (IAM) user to associate with this configuration.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SshPublicKey`

The public SSH key that is associated with the IAM user. To access instances, the IAM user must have or be given the corresponding private key.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SshUsername`

The user's SSH user name.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the IAM user ARN, such as `arn:aws:iam::123456789012:user/opsworksuser`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

- `SshUsername`

  The user's SSH user name, as a string.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example registers a public key to the `testUser` IAM user. The user can also use self-management to specify his or her own public key.

JSON

```
"userProfile": {
  "Type": "AWS::OpsWorks::UserProfile",
  "Properties": {
    "IamUserArn": {
      "Fn::GetAtt": ["testUser", "Arn"]
    },
    "AllowSelfManagement": "true",
    "SshPublicKey": "xyz1234567890"
  }
}
```

YAML

```
userProfile:
  Type: AWS::OpsWorks::UserProfile
  Properties:
    IamUserArn: !GetAtt [testUser, Arn]
    AllowSelfManagement: 'true'
    SshPublicKey: xyz1234567890
```

AWS::OpsWorks::Volume

The `AWS::OpsWorks::Volume` resource registers an Amazon Elastic Block Store (Amazon EBS) volume with an AWS OpsWorks stack.

Topics

- Syntax (p. 1885)
- Properties (p. 1885)
- Return Value (p. 1886)
- Example (p. 1886)

Syntax

JSON

```
{
  "Type" : "AWS::OpsWorks::Volume",
  "Properties" : {
    "Ec2VolumeId" : String,
    "MountPoint" : String,
    "Name" : String,
    "StackId" : String
  }
}
```

YAML

```
Type: "AWS::OpsWorks::Volume"
Properties:
  Ec2VolumeId: String
  MountPoint: String
  Name: String
  StackId: String
```

Properties

`Ec2VolumeId`

The ID of the Amazon EBS volume to register with the AWS OpsWorks stack.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`MountPoint`

The mount point for the Amazon EBS volume, such as `/mnt/disk1`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

A name for the Amazon EBS volume.

Required: No

Type: String

Update requires: No interruption (p. 120)

`StackId`

The ID of the AWS OpsWorks stack that AWS OpsWorks registers the volume to.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the AWS OpsWorks volume ID, such as `1ab23cd4-92ff-4501-b37c-example`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example registers the `ec2volume` volume with the `opsworksstack` stack, both of which are declared elsewhere in the same template.

JSON

```
"opsworksVolume": {
  "Type": "AWS::OpsWorks::Volume",
  "Properties": {
    "Ec2VolumeId": { "Ref": "ec2volume" },
    "MountPoint": "/dev/sdb",
    "Name": "testOpsWorksVolume",
    "StackId": { "Ref": "opsworksstack" }
  }
}
```

YAML

```
opsworksVolume:
  Type: AWS::OpsWorks::Volume
  Properties:
    Ec2VolumeId: !Ref 'ec2volume'
    MountPoint: /dev/sdb
    Name: testOpsWorksVolume
    StackId: !Ref 'opsworksstack'
```

Amazon Relational Database Service Resource Types Reference

This section contains reference information for all Amazon Relational Database Service resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::RDS::data-type-name
```

Topics

- AWS::RDS::DBCluster (p. 1887)
- AWS::RDS::DBClusterParameterGroup (p. 1896)
- AWS::RDS::DBInstance (p. 1898)
- AWS::RDS::DBParameterGroup (p. 1915)
- AWS::RDS::DBSecurityGroup (p. 1918)
- AWS::RDS::DBSecurityGroupIngress (p. 1922)
- AWS::RDS::DBSubnetGroup (p. 1924)
- AWS::RDS::EventSubscription (p. 1926)
- AWS::RDS::OptionGroup (p. 1929)

AWS::RDS::DBCluster

The `AWS::RDS::DBCluster` resource creates a cluster, such as an Aurora for Amazon RDS (Amazon Aurora) DB cluster. Amazon Aurora is a fully managed, MySQL-compatible, relational database engine. For more information, see Aurora on Amazon RDS in the *Amazon RDS User Guide*.

> **Note**
> Currently, you can create this resource only in regions in which Amazon Aurora is supported.

The default DeletionPolicy for `AWS::RDS::DBCluster` resources is `Snapshot`. For more information about how AWS CloudFormation deletes resources, see DeletionPolicy Attribute (p. 2273).

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::RDS::DBCluster",
  "Properties" :
  {
    "AvailabilityZones" : [ String, ... ],
    "BackupRetentionPeriod" : Integer,
    "DatabaseName" : String,
    "DBClusterIdentifier" : String,
    "DBClusterParameterGroupName" : String,
    "DBSubnetGroupName" : String,
    "Engine" : String,
    "EngineMode" : String,
    "EngineVersion" : String,
    "KmsKeyId" : String,
    "MasterUsername" : String,
    "MasterUserPassword" : String,
    "Port" : Integer,
    "PreferredBackupWindow" : String,
    "PreferredMaintenanceWindow" : String,
    "ReplicationSourceIdentifier" : String,
    "ScalingConfiguration" : ScalingConfiguration (p. 1895),
    "SnapshotIdentifier" : String,
```

```
    "StorageEncrypted" : Boolean,
    "Tags" : [ Resource Tag (p. 2258), ... ],
    "VpcSecurityGroupIds" : [ String, ... ]
  }
}
```

YAML

```
Type: "AWS::RDS::DBCluster"
Properties:
  AvailabilityZones:
    - String
  BackupRetentionPeriod: Integer
  DatabaseName: String
  DBClusterIdentifier: String
  DBClusterParameterGroupName: String
  DBSubnetGroupName: String
  Engine: String
  EngineMode: String
  EngineVersion: String
  KmsKeyId: String
  MasterUsername: String
  MasterUserPassword: String
  Port: Integer
  PreferredBackupWindow: String
  PreferredMaintenanceWindow: String
  ReplicationSourceIdentifier: String
  ScalingConfiguration" : ScalingConfiguration (p. 1895)
  SnapshotIdentifier: String
  StorageEncrypted: Boolean
  Tags:
    - Resource Tag (p. 2258)
  VpcSecurityGroupIds:
    - String
```

Properties

`AvailabilityZones`

A list of Availability Zones (AZs) in which DB instances in the cluster can be created.

Required: No

Type: String

Update requires: Replacement (p. 121)

`BackupRetentionPeriod`

The number of days for which automatic backups are retained. For more information, see CreateDBCluster in the *Amazon RDS API Reference*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`DatabaseName`

The name of your database. If you don't provide a name, Amazon Relational Database Service (Amazon RDS) won't create a database in this DB cluster. For naming constraints, see Naming Constraints in Amazon RDS in the *Amazon RDS User Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBClusterIdentifier`

The DB cluster identifier. This parameter is stored as a lowercase string.

Constraints:

- Must contain from 1 to 63 letters, numbers, or hyphens.
- First character must be a letter.
- Cannot end with a hyphen or contain two consecutive hyphens.

For additional information, see the `DBClusterIdentifier` parameter of the CreateDBCluster action in the *Amazon RDS API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBClusterParameterGroupName`

The name of the DB cluster parameter group to associate with this DB cluster.

> **Note**
> If this argument is omitted, `default.aurora5.6` is used. If `default.aurora5.6` is used, specifying `aurora-mysql` or `aurora-postgresql` for the `Engine` property might result in an error.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`DBSubnetGroupName`

A DB subnet group that you want to associate with this DB cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Engine`

The name of the database engine that you want to use for this DB cluster.

For valid values, see the `Engine` parameter of the CreateDBCluster action in the *Amazon RDS API Reference*.

> **Note**
> If you don't specify a value for the `DBClusterParameterGroupName` property and `default.aurora5.6` is used, specifying `aurora.mysql` or `aurora-postgresql` for this property might result in an error.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`EngineMode`

The DB engine mode of the DB cluster. Valid values include `provisioned` or `serverless`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`EngineVersion`

The version number of the database engine that you want to use.

Required: No

Type: String

Update requires: Replacement (p. 121)

`KmsKeyId`

The Amazon Resource Name (ARN) of the AWS Key Management Service master key that is used to encrypt the database instances in the DB cluster, such as `arn:aws:kms:us-east-1:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef`. If you enable the `StorageEncrypted` property but don't specify this property, the default master key is used. If you specify this property, you must set the `StorageEncrypted` property to `true`.

If you specify the `SnapshotIdentifier`, do not specify this property. The value is inherited from the snapshot DB cluster.

Required: No

Type: String

Update requires: Replacement (p. 121).

`MasterUsername`

The master user name for the DB instance.

Required: Conditional. You must specify this property unless you specify the `SnapshotIdentifier` property. In that case, do not specify this property.

Type: String

Update requires: Replacement (p. 121).

`MasterUserPassword`

The password for the master database user.

Required: Conditional. You must specify this property unless you specify the `SnapshotIdentifier` property. In that case, do not specify this property.

Type: String

Update requires: No interruption (p. 120)

`Port`

The port number on which the DB instances in the cluster can accept connections. If this argument is omitted, `3306` is used.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`PreferredBackupWindow`

if automated backups are enabled (see the `BackupRetentionPeriod` property), the daily time range in UTC during which you want to create automated backups.

For valid values, see the `PreferredBackupWindow` parameter of the CreateDBInstance action in the *Amazon RDS API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PreferredMaintenanceWindow`

The weekly time range (in UTC) during which system maintenance can occur.

For valid values, see the `PreferredMaintenanceWindow` parameter of the CreateDBInstance action in the *Amazon RDS API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120) or some interruptions (p. 121). For more information, see ModifyDBInstance in the *Amazon RDS API Reference*.

`ReplicationSourceIdentifier`

The Amazon Resource Name (ARN) of the source Amazon RDS DB instance or DB cluster, if this DB cluster is created as a Read Replica.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ScalingConfiguration`

For DB clusters in `serverless` DB engine mode, the scaling properties of the DB cluster.

Required: No

Type: ScalingConfiguration (p. 1895)

Update requires: No interruption (p. 120)

`SnapshotIdentifier`

The identifier for the DB cluster snapshot from which you want to restore.

Required: No

Type: String

Update requires: Replacement (p. 121)

`StorageEncrypted`

Indicates whether the DB instances in the cluster are encrypted.

If you specify the `SnapshotIdentifier` property, do not specify this property. The value is inherited from the snapshot DB cluster.

Required: Conditional. If you specify the `KmsKeyId` property, you must enable encryption.

Type: Boolean

Update requires: Replacement (p. 121).

`Tags`

The tags that you want to attach to this DB cluster.

Required: No

Type: A list of resource tags (p. 2258)

Update requires: No interruption (p. 120)

`VpcSecurityGroupIds`

A list of VPC security groups to associate with this DB cluster.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Endpoint.Address`

The connection endpoint for the DB cluster. For example: `mystack-mydbcluster-1apw1j4phylrk.cg034hpkmmjt.us-east-2.rds.amazonaws.com`.

`Endpoint.Port`

The port number that will accept connections on this DB cluster. For example: `3306`.

`ReadEndpoint.Address`

The reader endpoint for the DB cluster. For example: `mystack-mydbcluster-ro-1apw1j4phylrk.cg034hpkmmjt.us-east-2.rds.amazonaws.com`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following snippet creates an Amazon Aurora DB cluster and adds two DB instances to it. Because Amazon RDS automatically assigns a writer and reader DB instances in the cluster, use the cluster endpoint to read and write data, not the individual DB instance endpoints.

JSON

```
"RDSCluster" : {

Amazon Relational Database Service DBCluster ScalingConfiguration

The `ScalingConfiguration` property type specifies the scaling configuration of an Aurora Serverless DB cluster.

`ScalingConfiguration` is a property of the AWS::RDS::DBCluster (p. 1887) resource type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "AutoPause" : Boolean,
  "MaxCapacity" : Integer,
  "MinCapacity" : Integer,
  "SecondsUntilAutoPause" : Integer
}
```

YAML

```
AutoPause: Boolean
MaxCapacity: Integer
MinCapacity: Integer
SecondsUntilAutoPause: Integer
```

Properties

`AutoPause`

A value that specifies whether to allow or disallow automatic pause for an Aurora DB cluster in serverless DB engine mode. A DB cluster can be paused only when it's idle (it has no connections).

> **Note**
> If a DB cluster is paused for more than seven days, the DB cluster might be backed up with a snapshot. In this case, the DB cluster is restored when there is a request to connect to it.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`MaxCapacity`

The maximum capacity for an Aurora DB cluster in serverless DB engine mode.

Valid capacity values are 2, 4, 8, 16, 32, 64, 128, and 256.

The maximum capacity must be greater than or equal to the minimum capacity.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`MinCapacity`

The minimum capacity for an Aurora DB cluster in serverless DB engine mode.

Valid capacity values are 2, 4, 8, 16, 32, 64, 128, and 256.

The maximum capacity must be greater than or equal to the minimum capacity.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`SecondsUntilAutoPause`

The time, in seconds, before an Aurora DB cluster in `serverless` mode is paused.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

See Also

- ScalingConfiguration in the *Amazon RDS API Reference*

AWS::RDS::DBClusterParameterGroup

The `AWS::RDS::DBClusterParameterGroup` resource creates a new Amazon Relational Database Service (Amazon RDS) database (DB) cluster parameter group. For more information about DB cluster parameter groups, see Appendix: DB Cluster and DB Instance Parameters in the *Amazon RDS User Guide*.

> **Note**
> Applying a parameter group to a DB cluster might require instances to reboot, resulting in a database outage while the instances reboot.

Topics

- Syntax (p. 1896)
- Properties (p. 1897)
- Return Values (p. 1898)
- Example (p. 1898)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::RDS::DBClusterParameterGroup",
  "Properties" : {
    "Description" : String,
    "Family" : String,
    "Parameters" : DBParameters,
```

```
    "Tags" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: "AWS::RDS::DBClusterParameterGroup"
Properties:
  Description: String
  Family: String
  Parameters: DBParameters
  Tags:
    Resource Tag
```

Properties

`Description`

A friendly description for this DB cluster parameter group.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Family`

The database family of this DB cluster parameter group, such as `aurora5.6`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Parameters`

The parameters to set for this DB cluster parameter group. For a list of parameter keys, see Appendix: DB Cluster and DB Instance Parameters in the *Amazon RDS User Guide*.

Changes to dynamic parameters are applied immediately. Changes to static parameters require a reboot without failover to the DB instance that is associated with the parameter group before the change can take effect.

Required: Yes

Type: A JSON object consisting of string key-value pairs, as shown in the following example:

```
"Parameters" : {
   "Key1" : "Value1",
   "Key2" : "Value2",
   "Key3" : "Value3"
}
```

Update requires: No interruption (p. 120) or some interruptions (p. 121), depending on the parameters that you update.

`Tags`

The tags that you want to attach to this parameter group.

Required: No

Type: A list of resource tags (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following snippet creates a parameter group that sets the character set database to UTF32:

JSON

```
"RDSDBClusterParameterGroup" : {
  "Type" : "AWS::RDS::DBClusterParameterGroup",
  "Properties" : {
    "Parameters" : {
      "character_set_database" : "utf32"
    },
    "Family" : "aurora5.6",
    "Description" : "A sample parameter group"
  }
}
```

YAML

```
RDSDBClusterParameterGroup:
  Type: "AWS::RDS::DBClusterParameterGroup"
  Properties:
    Parameters:
      character_set_database: "utf32"
    Family: "aurora5.6"
    Description: "A sample parameter group"
```

AWS::RDS::DBInstance

The `AWS::RDS::DBInstance` type creates an Amazon Relational Database Service (Amazon RDS) DB instance. For detailed information about configuring RDS DB instances, see CreateDBInstance.

> **Important**
> If a DB instance is deleted or replaced during an update, AWS CloudFormation deletes all automated snapshots. However, it retains manual DB snapshots. During an update that requires replacement, you can apply a stack policy to prevent DB instances from being replaced. For more information, see Prevent Updates to Stack Resources (p. 143).

- Syntax (p. 1899)
- Properties (p. 1900)
- Updating and Deleting AWS::RDS::DBInstance Resources (p. 1828)

- Return Values (p. 1912)
- Examples (p. 1912)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::RDS::DBInstance",
  "Properties" :
  {
    "AllocatedStorage (p. 1900)" : String,
    "AllowMajorVersionUpgrade" : Boolean,
    "AutoMinorVersionUpgrade (p. 1901)" : Boolean,
    "AvailabilityZone (p. 1901)" : String,
    "BackupRetentionPeriod (p. 1901)" : String,
    "CharacterSetName" : String,
    "CopyTagsToSnapshot" : Boolean,
    "DBClusterIdentifier" : String,
    "DBInstanceClass (p. 1902)" : String,
    "DBInstanceIdentifier" : String,
    "DBName (p. 1902)" : String,
    "DBParameterGroupName (p. 1903)" : String,
    "DBSecurityGroups (p. 1903)" : [ String, ... ],
    "DBSnapshotIdentifier (p. 1904)" : String,
    "DBSubnetGroupName (p. 1905)" : String,
    "Domain" : String,
    "DomainIAMRoleName" : String,
    "Engine (p. 1905)" : String,
    "EngineVersion (p. 1906)" : String,
    "Iops (p. 1906)" : Integer,
    "KmsKeyId" : String,
    "LicenseModel (p. 1907)" : String,
    "MasterUsername (p. 1907)" : String,
    "MasterUserPassword (p. 1907)" : String,
    "MonitoringInterval (p. 1907)" : Integer,
    "MonitoringRoleArn (p. 1907)" : String,
    "MultiAZ (p. 1908)" : Boolean,
    "OptionGroupName" : String,
    "Port (p. 1908)" : String,
    "PreferredBackupWindow (p. 1908)" : String,
    "PreferredMaintenanceWindow (p. 1908)" : String,
    "PubliclyAccessible" : Boolean,
    "SourceDBInstanceIdentifier" : String,
    "SourceRegion" : String,
    "StorageEncrypted" : Boolean,
    "StorageType" : String,
    "Tags (p. 1910)" : [ Resource Tag, ... ],
    "Timezone" : String,
    "VPCSecurityGroups (p. 1911)" : [ String, ... ]
  }
}
```

YAML

```
Type: AWS::RDS::DBInstance
Properties:
  AllocatedStorage (p. 1900): String
  AllowMajorVersionUpgrade: Boolean
  AutoMinorVersionUpgrade (p. 1901): Boolean
```

```
  AvailabilityZone (p. 1901): String
  BackupRetentionPeriod (p. 1901): String
  CharacterSetName: String
  CopyTagsToSnapshot: Boolean
  DBClusterIdentifier: String
  DBInstanceClass (p. 1902): String
  DBInstanceIdentifier: String
  DBName (p. 1902): String
  DBParameterGroupName (p. 1903): String
  DBSecurityGroups (p. 1903):
    - String
  DBSnapshotIdentifier (p. 1904): String
  DBSubnetGroupName (p. 1905): String
  Domain: String
  DomainIAMRoleName: String
  Engine (p. 1905): String
  EngineVersion (p. 1906): String
  Iops (p. 1906): Integer
  KmsKeyId: String
  LicenseModel (p. 1907): String
  MasterUsername (p. 1907): String
  MasterUserPassword (p. 1907): String
  MonitoringInterval (p. 1907): Integer
  MonitoringRoleArn (p. 1907): String
  MultiAZ (p. 1908): Boolean
  OptionGroupName: String
  Port (p. 1908): String
  PreferredBackupWindow (p. 1908): String
  PreferredMaintenanceWindow (p. 1908): String
  PubliclyAccessible: Boolean
  SourceDBInstanceIdentifier: String
  SourceRegion: String
  StorageEncrypted: Boolean
  StorageType: String
  Tags (p. 1910):
    Resource Tag
  Timezone: String
  VPCSecurityGroups (p. 1911):
    - String
```

Properties

`AllocatedStorage`

The allocated storage size, specified in gigabytes (GB).

If any value is set in the `Iops` parameter, `AllocatedStorage` must be at least 100 GB, which corresponds to the minimum `Iops` value of 1,000. If you increase the `Iops` value (in 1,000 IOPS increments), then you must also increase the `AllocatedStorage` value (in 100-GB increments).

Required: Conditional. This property is required except when you specify the `DBClusterIdentifier` property or when you create a read replica from AWS CloudFormation by using the `AWS::RDS::DBInstance` resource. In these cases, don't specify this property.

Type: String

Update requires: No interruption (p. 120)

`AllowMajorVersionUpgrade`

If you update the `EngineVersion` property to a version that's different from the DB instance's current major version, set this property to `true`. For more information, see ModifyDBInstance in the *Amazon RDS API Reference*.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`AutoMinorVersionUpgrade`

Indicates that minor engine upgrades are applied automatically to the DB instance during the maintenance window. The default value is `true`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120) or some interruptions (p. 121). For more information, see ModifyDBInstance in the *Amazon RDS API Reference*.

`AvailabilityZone`

The name of the Availability Zone where the DB instance is located. You can't set the `AvailabilityZone` parameter if the `MultiAZ` parameter is set to `true`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`BackupRetentionPeriod`

The number of days during which automatic DB snapshots are retained.

> **Important**
> If this DB instance is deleted or replaced during an update, AWS CloudFormation deletes all automated snapshots. However, it retains manual DB snapshots.

Required: No

Type: String

Update requires: No interruption (p. 120) or some interruptions (p. 121). For more information, see ModifyDBInstance in the *Amazon RDS API Reference*.

`CharacterSetName`

For supported engines, specifies the character set to associate with the DB instance. For more information, see Appendix: Oracle Character Sets Supported in Amazon RDS in the *Amazon RDS User Guide*.

If you specify the `DBSnapshotIdentifier` or `SourceDBInstanceIdentifier` property, don't specify this property. The value is inherited from the snapshot or source DB instance.

Required: No

Type: String

Update requires: Replacement (p. 121)

`CopyTagsToSnapshot`

Indicates whether to copy all of the user-defined tags from the DB instance to snapshots of the DB instance. By default, Amazon RDS doesn't copy tags to snapshots. Amazon RDS doesn't copy tags

with the `aws::` prefix unless it's the DB instance's final snapshot (the snapshot when you delete the DB instance).

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`DBClusterIdentifier`

The name of an existing DB cluster that this instance is associated with. If you specify this property, specify `aurora` for the `Engine` property and don't specify any of the following properties: `AllocatedStorage`, `BackupRetentionPeriod`, `CharacterSetName`, `DBName`, `DBSecurityGroups`, `MasterUsername`, `MasterUserPassword`, `OptionGroupName`, `PreferredBackupWindow`, `PreferredMaintenanceWindow`, `Port`, `SourceDBInstanceIdentifier`, `StorageType`, or `VPCSecurityGroups`.

Amazon RDS assigns the first DB instance in the cluster as the primary, and additional DB instances as replicas.

If you specify this property, the default deletion policy is `Delete`. Otherwise, the default deletion policy is `Snapshot`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBInstanceClass`

The name of the compute and memory capacity classes of the DB instance.

Required: Yes

Type: String

Update requires: Some interruptions (p. 121)

`DBInstanceIdentifier`

A name for the DB instance. If you specify a name, AWS CloudFormation converts it to lowercase. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the DB instance. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBName`

The name of the DB instance that was provided at the time of creation, if one was specified. This same name is returned for the life of the DB instance.

> **Important**
> If you specify the `DBSnapshotIdentifier` (p. 1904) property, AWS CloudFormation ignores this property.

If you restore DB instances from snapshots, this property doesn't apply to the MySQL, PostgreSQL, or MariaDB engines.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBParameterGroupName`

The name of an existing DB parameter group or a reference to an AWS::RDS::DBParameterGroup (p. 1915) resource created in the template.

Required: No

Type: String

Update requires: No interruption (p. 120) or some interruptions (p. 121). If any of the data members of the referenced parameter group are changed during an update, the DB instance might need to be restarted, which causes some interruption. If the parameter group contains static parameters, whether they were changed or not, an update triggers a reboot.

`DBSecurityGroups`

A list of the DB security groups to assign to the DB instance. The list can include both the name of existing DB security groups or references to AWS::RDS::DBSecurityGroup (p. 1918) resources created in the template.

If you set `DBSecurityGroups`, you must not set VPCSecurityGroups (p. 1911), and vice versa. Also, note that the `EC2VpcId` property exists only for backwards compatibility with older regions and is no longer recommended for providing security information to an RDS DB instance. Instead, use `VPCSecurityGroups`.

Important
If you specify this property, AWS CloudFormation sends only the following properties (if specified) to Amazon RDS *during create operations*:

- `AllocatedStorage`
- `AutoMinorVersionUpgrade`
- `AvailabilityZone`
- `BackupRetentionPeriod`
- `CharacterSetName`
- `DBInstanceClass`
- `DBName`
- `DBParameterGroupName`
- `DBSecurityGroups`
- `DBSubnetGroupName`
- `Engine`
- `EngineVersion`
- `Iops`
- `LicenseModel`
- `MasterUsername`
- `MasterUserPassword`
- `MultiAZ`
- `OptionGroupName`

- `PreferredBackupWindow`
- `PreferredMaintenanceWindow`

If you specify this property, AWS CloudFormation sends only the following properties (if specified) to Amazon RDS *during updates*:

- `AllocatedStorage`
- `AutoMinorVersionUpgrade`
- `AllowMajorVersionUpgrade`
- `BackupRetentionPeriod`
- `DBInstanceClass`
- `DBParameterGroupName`
- `DBSecurityGroups`
- `DBInstanceIdentifier`
- `EngineVersion`
- `Iops`
- `MasterUserPassword`
- `MultiAZ`
- `OptionGroupName`
- `PreferredBackupWindow`
- `PreferredMaintenanceWindow`

All other properties are ignored. Specify a virtual private cloud (VPC) security group if you want to submit other properties, such as `StorageType`, `StorageEncrypted`, or `KmsKeyId`. If you're already using the `DBSecurityGroups` property, you can't use these other properties by updating your DB instance to use a VPC security group. You must recreate the DB instance.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`DBSnapshotIdentifier`

The name or Amazon Resource Name (ARN) of the DB snapshot that's used to restore the DB instance. If you're restoring from a shared manual DB snapshot, you must specify the ARN of the snapshot.

By specifying this property, you can create a DB instance from the specified DB snapshot. If the `DBSnapshotIdentifier` property is an empty string or the `AWS::RDS::DBInstance` declaration has no `DBSnapshotIdentifier` property, AWS CloudFormation creates a new database. If the property contains a value (other than an empty string), AWS CloudFormation creates a database from the specified snapshot. If a snapshot with the specified name doesn't exist, AWS CloudFormation can't create the database and it rolls back the stack.

Some DB instance properties aren't valid when you restore from a snapshot, such as the `MasterUsername` and `MasterUserPassword` properties. For information about the properties that you can specify, see the RestoreDBInstanceFromDBSnapshot action in the *Amazon RDS API Reference*.

Important
If you specify this property, AWS CloudFormation ignores the `DBName` (p. 1902) property.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DBSubnetGroupName`

A DB subnet group to associate with the DB instance. If you update this value, the new subnet group must be a subnet group in a new VPC.

If there's no DB subnet group, then the instance isn't a VPC DB instance.

For more information about using Amazon RDS in a VPC, see Using Amazon RDS with Amazon Virtual Private Cloud (VPC) in the *Amazon Relational Database Service Developer Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Domain`

For an Amazon RDS DB instance that's running Microsoft SQL Server, the Active Directory directory ID to create the instance in. Amazon RDS uses Windows Authentication to authenticate users that connect to the DB instance. For more information, see Using Windows Authentication with an Amazon RDS DB Instance Running Microsoft SQL Server in the *Amazon RDS User Guide*.

If you specify this property, you must specify a SQL Server engine for the `Engine` property.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DomainIAMRoleName`

The name of an IAM role that Amazon RDS uses when calling the AWS Directory Service APIs.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Engine`

The database engine that the DB instance uses. This property is optional when you specify the `DBSnapshotIdentifier` property to create DB instances.

For valid values, see the `Engine` parameter of the CreateDBInstance action in the *Amazon RDS API Reference*.

If you specify `aurora` as the database engine, you must also specify the `DBClusterIdentifier` property.

> **Note**
> If you've specified `oracle-se` or `oracle-se1` as the database engine, you can update the database engine to `oracle-se2` without the database instance being replaced. For information on the deprecation of support for Oracle version 12.1.0.1, see Deprecation of Oracle 12.1.0.1 in the *Amazon Relational Database Service User Guide*.

Required: Conditional

Type: String

Update requires: Replacement (p. 121)

`EngineVersion`

The version number of the database engine that the DB instance uses.

> **Note**
> To prevent automatic upgrades, be sure to specify the full version number (for example, 5.6.13). If the default version for the database engine changes and you specify only the major version (for example, 5.6), your DB instance will be upgraded to use the latest default version.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`Iops`

The number of I/O operations per second (IOPS) that the database provisions. The value must be equal to or greater than `1000`.

If you specify this property, you must follow the range of allowed ratios of your requested IOPS rate to the amount of storage that you allocate (IOPS to allocated storage). For example, you can provision an Oracle database instance with `1000` IOPS and `200` GB of storage (a ratio of 5:1), or specify 2000 IOPS with 200 GB of storage (a ratio of 10:1). For more information, see Amazon RDS Provisioned IOPS Storage to Improve Performance in the *Amazon RDS User Guide*.

Required: Conditional. If you specify `io1` for the `StorageType` property, you must specify this property.

Type: Integer

Update requires: No interruption (p. 120)

`KmsKeyId`

The ARN of the AWS Key Management Service (AWS KMS) master key that's used to encrypt the DB instance, such as `arn:aws:kms:us-east-1:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef`. If you enable the `StorageEncrypted` property but don't specify this property, AWS CloudFormation uses the default master key. If you specify this property, you must set the `StorageEncrypted` property to `true`.

If you specify the `SourceDBInstanceIdentifier` property, the value is inherited from the source DB instance if the read replica is created in the same region. If you specify this property when you create a read replica from an unencrypted DB instance, the read replica is encrypted.

If you create an encrypted read replica in a different AWS Region, then you must specify a KMS key for the destination AWS Region. KMS encryption keys are specific to the region that they're created in, and you can't use encryption keys from one region in another region.

If you specify `DBSecurityGroups`, AWS CloudFormation ignores this property. To specify both a security group and this property, you must use a VPC security group. For more information about Amazon RDS and VPC, see Using Amazon RDS with Amazon VPC in the *Amazon RDS User Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`LicenseModel`

The license model of the DB instance.

> **Note**
> If you've specified `DBSecurityGroups` and then you update the license model, AWS CloudFormation replaces the underlying EC2 host. This will incur some interruptions to database availability.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`MasterUsername`

The master user name for the DB instance.

> **Note**
> If you specify the `SourceDBInstanceIdentifier` or `DBSnapshotIdentifier` property, don't specify this property. The value is inherited from the source DB instance or snapshot.

Required: Conditional

Type: String

Update requires: Replacement (p. 121)

`MasterUserPassword`

The master password for the DB instance.

> **Note**
> If you specify the `SourceDBInstanceIdentifier` or `DBSnapshotIdentifier` property, don't specify this property. The value is inherited from the source DB instance or snapshot.

Required: Conditional

Type: String

Update requires: No interruption (p. 120)

`MonitoringInterval`

The interval, in seconds, between points when Amazon RDS collects enhanced monitoring metrics for the DB instance. To disable metrics collection, specify `0`.

For default and valid values, see the `MonitoringInterval` parameter for the CreateDBInstance action in the *Amazon RDS API Reference*.

Required: Conditional. If you specify the `MonitoringRoleArn` property, specify a value other than `0` for `MonitoringInterval`.

Type: Integer

Update requires: No interruption (p. 120) or some interruptions (p. 121). For more information, see ModifyDBInstance in the *Amazon RDS API Reference*.

`MonitoringRoleArn`

The ARN of the AWS Identity and Access Management (IAM) role that permits Amazon RDS to send enhanced monitoring metrics to Amazon CloudWatch, for example, `arn:aws:iam::123456789012:role/emaccess`. For information on creating a monitoring role, see To create an IAM role for Amazon RDS Enhanced Monitoring in the *Amazon RDS User Guide*.

Required: Conditional. If you specify a value other than `0` for the `MonitoringInterval` property, specify a value for `MonitoringRoleArn`.

Type: String

Update requires: No interruption (p. 120)

`MultiAZ`

Specifies if the database instance is a multiple Availability Zone deployment. You can't set the `AvailabilityZone` parameter if the `MultiAZ` parameter is set to true. Amazon Aurora storage is replicated across all the Availability Zones and doesn't require the `MultiAZ` option to be set.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`OptionGroupName`

The option group that this DB instance is associated with.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Port`

The port for the instance.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PreferredBackupWindow`

The daily time range during which automated backups are performed if automated backups are enabled, as determined by the `BackupRetentionPeriod` property. For valid values, see the `PreferredBackupWindow` parameter for the CreateDBInstance action in the *Amazon RDS API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PreferredMaintenanceWindow`

The weekly time range (in UTC) during which system maintenance can occur. For valid values, see the `PreferredMaintenanceWindow` parameter for the CreateDBInstance action in the *Amazon RDS API Reference*.

> **Note**
> This property applies when AWS CloudFormation initially creates the DB instance. If you use AWS CloudFormation to update the DB instance, those updates are applied immediately.

Required: No

Type: String

Update requires: No interruption (p. 120) or some interruptions (p. 121). For more information, see ModifyDBInstance in the *Amazon RDS API Reference*.

`PubliclyAccessible`

Indicates whether the DB instance is an internet-facing instance. If you specify `true`, AWS CloudFormation creates an instance with a publicly resolvable DNS name, which resolves to a public IP address. If you specify `false`, AWS CloudFormation creates an internal instance with a DNS name that resolves to a private IP address.

The default behavior value depends on your VPC setup and the database subnet group. For more information, see the `PubliclyAccessible` parameter in CreateDBInstance in the *Amazon RDS API Reference*.

If this resource has a public IP address and is also in a VPC that is defined in the same template, you must use the `DependsOn` attribute to declare a dependency on the VPC-gateway attachment. For more information, see DependsOn Attribute (p. 2275).

Note
If you specify `DBSecurityGroups`, AWS CloudFormation ignores this property. To specify a security group and this property, you must use a VPC security group. For more information about Amazon RDS and VPC, see Using Amazon RDS with Amazon VPC in the *Amazon RDS User Guide*.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`SourceDBInstanceIdentifier`

If you want to create a read replica DB instance, specify the ID of the source DB instance. Each DB instance can have a limited number of read replicas. For more information, see Working with Read Replicas in the *Amazon Relational Database Service Developer Guide*.

The `SourceDBInstanceIdentifier` property determines whether a DB instance is a read replica. If you remove the `SourceDBInstanceIdentifier` property from your template and then update your stack, AWS CloudFormation deletes the read replica and creates a new DB instance (not a read replica).

Important

- If you specify a source DB instance that uses VPC security groups, we recommend that you specify the `VPCSecurityGroups` property. If you don't specify the property, the read replica inherits the value of the `VPCSecurityGroups` property from the source DB when you create the replica. However, if you update the stack, AWS CloudFormation reverts the replica's `VPCSecurityGroups` property to the default value because it's not defined in the stack's template. This change might cause unexpected issues.
- Read replicas don't support deletion policies. AWS CloudFormation ignores any deletion policy that's associated with a read replica.
- If you specify `SourceDBInstanceIdentifier`, don't set the `MultiAZ` property to `true`, and don't specify the `DBSnapshotIdentifier` property. You can't deploy read replicas in multiple Availability Zones, and you can't create a read replica from a snapshot.
- Don't set the `BackupRetentionPeriod`, `DBName`, `MasterUsername`, `MasterUserPassword`, and `PreferredBackupWindow` properties. The database attributes are inherited from the source DB instance, and backups are disabled for read replicas.
- If the source DB instance is in a different region than the read replica, specify an ARN for a valid DB instance. For more information, see Constructing a Amazon RDS Amazon Resource Name (ARN) in the *Amazon RDS User Guide*.

- For DB instances in Amazon Aurora clusters, don't specify this property. Amazon RDS automatically assigns writer and reader DB instances.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SourceRegion`

The ID of the region that contains the source DB instance for the read replica.

Required: No

Type: String

Update requires: Replacement (p. 121)

`StorageEncrypted`

Indicates whether the DB instance is encrypted.

If you specify the `DBClusterIdentifier`, `DBSnapshotIdentifier`, or `SourceDBInstanceIdentifier` property, don't specify this property. The value is inherited from the cluster, snapshot, or source DB instance.

Required: Conditional. If you specify the `KmsKeyId` property, you must enable encryption.

Type: Boolean

Update requires: Replacement (p. 121)

`StorageType`

The storage type associated with this DB instance.

For the default and valid values, see the `StorageType` parameter of the CreateDBInstance action in the *Amazon RDS API Reference*.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) for this DB instance.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`Timezone`

The time zone of the DB instance, which you can specify to match the time zone of your applications. To see which engines support time zones, see the `Timezone` parameter for the CreateDBInstance action in the *Amazon RDS API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`VPCSecurityGroups`

A list of the VPC security group IDs to assign to the DB instance. The list can include both the physical IDs of existing VPC security groups and references to AWS::EC2::SecurityGroup (p. 1225) resources created in the template.

If you set `VPCSecurityGroups`, you must not set DBSecurityGroups (p. 1903), and vice versa.

Important
You can migrate a DB instance in your stack from an RDS DB security group to a VPC security group, but keep the following in mind:

- You can't revert to using an RDS security group after you establish a VPC security group membership.
- When you migrate your DB instance to VPC security groups, if your stack update rolls back because the DB instance update fails or because an update fails in another AWS CloudFormation resource, the rollback fails because it can't revert to an RDS security group.
- To use the properties that are available when you use a VPC security group, you must recreate the DB instance. If you don't, AWS CloudFormation submits only the property values that are listed in the DBSecurityGroups (p. 1903) property.

To avoid this situation, migrate your DB instance to using VPC security groups only when that is the only change in your stack template.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

Updating and Deleting AWS::RDS::DBInstance Resources

Updating DB Instances

When properties labeled "*Update requires*: Replacement (p. 121)" are updated, AWS CloudFormation first creates a replacement DB instance, then changes references from other dependent resources to point to the replacement DB instance, and finally deletes the old DB instance.

Important
We highly recommend that you take a snapshot of the database before updating the stack. If you don't, you lose the data when AWS CloudFormation replaces your DB instance. To preserve your data, perform the following procedure:

1. Deactivate any applications that are using the DB instance so that there's no activity on the DB instance.
2. Create a snapshot of the DB instance. For more information about creating DB snapshots, see Creating a DB snapshot.
3. If you want to restore your instance using a DB snapshot, modify the updated template with your DB instance changes and add the `DBSnapshotIdentifier` property with the ID of the DB snapshot that you want to use.
4. Update the stack.

For more information about updating other properties of this resource, see ModifyDBInstance. For more information about updating stacks, see AWS CloudFormation Stacks Updates (p. 120).

Deleting DB Instances

You can set a deletion policy for your DB instance to control how AWS CloudFormation handles the instance when the stack is deleted. For Amazon RDS DB instances, you can choose to *retain* the instance, to *delete* the instance, or to *create a snapshot* of the instance. The default AWS CloudFormation behavior depends on the `DBClusterIdentifier` property:

- For `AWS::RDS::DBInstance` resources that don't specify the `DBClusterIdentifier` property, AWS CloudFormation saves a snapshot of the DB instance.
- For `AWS::RDS::DBInstance` resources that do specify the `DBClusterIdentifier` property, AWS CloudFormation deletes the DB instance.

For more information, see DeletionPolicy Attribute (p. 2273).

Return Values

Ref

When you provide the RDS DB instance's logical name to the `Ref` intrinsic function, `Ref` returns the `DBInstanceIdentifier`. For example: `mystack-mydb-ea5ugmfvuaxg`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

- **Endpoint.Address**

  The connection endpoint for the database. For example: `mystack-mydb-1apw1j4phylrk.cg034hpkmmjt.us-east-2.rds.amazonaws.com`.
- **Endpoint.Port**

  The port number on which the database accepts connections. For example: `3306`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

DBInstance with a set MySQL version, Tags and DeletionPolicy

This example shows how to set the MySQL version that has a `DeletionPolicy Attribute (p. 2273)` set. With the `DeletionPolicy` set to `Snapshot`, AWS CloudFormation takes a snapshot of this DB instance before deleting it during stack deletion. A tag that contains a friendly name for the database is also set.

JSON

```
"MyDB" : {
   "Type" : "AWS::RDS::DBInstance",
   "Properties" : {
      "DBName" : { "Ref" : "DBName" },
      "AllocatedStorage" : { "Ref" : "DBAllocatedStorage" },
      "DBInstanceClass" : { "Ref" : "DBInstanceClass" },
      "Engine" : "MySQL",
      "EngineVersion" : "5.6.13",
```

```
      "MasterUsername" : { "Ref" : "DBUser" },
      "MasterUserPassword" : { "Ref" : "DBPassword" },
      "Tags" : [ { "Key" : "Name", "Value" : "My SQL Database" } ]
   },
   "DeletionPolicy" : "Snapshot"
}
```

YAML

```
MyDB:
  Type: AWS::RDS::DBInstance
  Properties:
    DBName:
      Ref: "DBName"
    AllocatedStorage:
      Ref: "DBAllocatedStorage"
    DBInstanceClass:
      Ref: "DBInstanceClass"
    Engine: "MySQL"
    EngineVersion: "5.6.13"
    MasterUsername:
      Ref: "DBUser"
    MasterUserPassword:
      Ref: "DBPassword"
    Tags:
      -
        Key: "Name"
        Value: "My SQL Database"
  DeletionPolicy: "Snapshot"
```

DBInstance with Provisioned IOPS

This example sets a provisioned IOPS value in the Iops (p. 1906) property. Note that the AllocatedStorage (p. 1900) property is set according to the 10:1 ratio between IOPS and GiBs of storage.

JSON

```
"MyDB" : {
   "Type" : "AWS::RDS::DBInstance",
   "Properties" : {
      "AllocatedStorage" : "100",
      "DBInstanceClass" : "db.m1.small",
      "Engine" : "MySQL",
      "EngineVersion" : "5.6.13",
      "Iops" : "1000",
      "MasterUsername" : { "Ref" : "DBUser" },
      "MasterUserPassword" : { "Ref" : "DBPassword" }
   }
}
```

YAML

```
MyDB:
  Type: AWS::RDS::DBInstance
  Properties:
    AllocatedStorage: "100"
    DBInstanceClass: "db.m1.small"
    Engine: "MySQL"
    EngineVersion: "5.6.13"
    Iops: "1000"
```

```
    MasterUsername:
      Ref: "DBUser"
    MasterUserPassword:
      Ref: "DBPassword"
```

Cross-Region Encrypted Read Replica

The following example creates an encrypted read replica from a cross-region source DB instance.

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Description": "RDS Storage Encrypted",

  "Parameters": {
    "SourceDBInstanceIdentifier": {
      "Type": "String"
    },
    "DBInstanceType" : {
      "Type" : "String"
    },
    "SourceRegion": {
      "Type": "String"
    }
  },
  "Resources": {
    "MyKey" : {
      "Type" : "AWS::KMS::Key",
      "Properties" : {
        "KeyPolicy" : {
          "Version": "2012-10-17",
          "Id": "key-default-1",
          "Statement": [
            {
              "Sid": "Enable IAM User Permissions",
              "Effect": "Allow",
              "Principal": {
                "AWS": { "Fn::Join" : ["" , ["arn:aws:iam::", {"Ref" :
 "AWS::AccountId"} ,":root" ]] }
              },
              "Action": "kms:*",
              "Resource": "*"
            }
          ]
        }
      }
    },
    "MyDBSmall": {
      "Type": "AWS::RDS::DBInstance",
      "Properties": {
        "DBInstanceClass": { "Ref" : "DBInstanceType" },
        "SourceDBInstanceIdentifier": { "Ref" : "SourceDBInstanceIdentifier" },
        "SourceRegion": { "Ref" : "SourceRegion" },
        "KmsKeyId" :  { "Ref" : "MyKey" }
      }
    }
  },
  "Outputs" : {
    "InstanceId" : {
      "Description" : "InstanceId of the newly created RDS Instance",
      "Value" : { "Ref" : "MyDBSmall" }
    }
  }
```

```
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Description: RDS Storage Encrypted
Parameters:
  SourceDBInstanceIdentifier:
    Type: String
  DBInstanceType:
    Type: String
  SourceRegion:

      KmsKeyId: !Ref MyKey
Outputs:
  InstanceId:
    Description: InstanceId of the newly created RDS Instance
    Value: !Ref MyDBSmall
```

AWS::RDS::DBParameterGroup

Creates a custom parameter group for an RDS database family. For more information about RDS parameter groups, see Working with DB Parameter Groups in the *Amazon Relational Database Service User Guide*.

This type can be declared in a template and referenced in the `DBParameterGroupName` parameter of AWS::RDS::DBInstance (p. 1898).

> **Note**
> Applying a ParameterGroup to a DBInstance may require the instance to reboot, resulting in a database outage for the duration of the reboot.

Topics

- Syntax (p. 1916)
- Properties (p. 1916)
- Return Values (p. 1917)
- Example (p. 1917)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::RDS::DBParameterGroup",
   "Properties" : {
      "Description (p. 1916)" : String,
      "Family (p. 1916)" : String,
      "Parameters (p. 1916)" : DBParameters,
      "Tags" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::RDS::DBParameterGroup
Properties:
  Description (p. 1916): String
  Family (p. 1916): String
  Parameters (p. 1916):
    DBParameters
  Tags:
    - Resource Tag
```

Properties

`Description`

A friendly description of the RDS parameter group. For example, `"My Parameter Group"`.

Required: Yes

Type: String

Update requires: Updates are not supported.

`Family`

The database family of this RDS parameter group. For example, `"MySQL5.1"`.

Required: Yes

Type: String

Update requires: Updates are not supported.

`Parameters`

The parameters to set for this RDS parameter group.

Required: No

Type: A JSON object consisting of string key-value pairs, as shown in the following example:

```
"Parameters" : {
   "Key1" : "Value1",
   "Key2" : "Value2",
```

```
    "Key3" : "Value3"
}
```

Update requires: No interruption (p. 120) or Some interruptions (p. 121). Changes to dynamic parameters are applied immediately. During an update, if you have static parameters (whether they were changed or not), triggers AWS CloudFormation to reboot the associated DB instance without failover.

`Tags`

The tags that you want to attach to the RDS parameter group.

Required: No

Type: A list of resource tags (p. 2258).

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyDBParameterGroup" }
```

For the RDS::DBParameterGroup with the logical ID "MyDBParameterGroup", `Ref` will return the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following snippet creates a parameter group for an Aurora DB cluster that applies the `IGNORE_SPACE` SQL mode.

JSON

```
"RDSDBParameterGroup": {
  "Type": "AWS::RDS::DBParameterGroup",
  "Properties" : {
    "Description" : "CloudFormation Sample Parameter Group",
    "Family" : "aurora5.6",
    "Parameters" : {
      "sql_mode": "IGNORE_SPACE"
    }
  }
}
```

YAML

```
RDSDBParameterGroup:
  Type: AWS::RDS::DBParameterGroup
  Properties:
    Description: CloudFormation Sample Parameter Group
    Family: aurora5.6
    Parameters:
      sql_mode: IGNORE_SPACE
```

AWS::RDS::DBSecurityGroup

The AWS::RDS::DBSecurityGroup type is used to create or update an Amazon RDS DB Security Group. For more information about DB security groups, see Working with DB Security Groups in the *Amazon Relational Database Service Developer Guide*. For details on the settings for DB security groups, see CreateDBSecurityGroup.

> **Note**
> If you use DB security groups, the settings that you can specify for your DB instances are limited. For more information, see the DBSecurityGroups (p. 1903) property.

When you specify an AWS::RDS::DBSecurityGroup as an argument to the `Ref` function, AWS CloudFormation returns the value of the `DBSecurityGroupName`.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::RDS::DBSecurityGroup",
   "Properties" :
   {
      "EC2VpcId (p. 1918)" : { "Ref" : "myVPC" },
      "DBSecurityGroupIngress (p. 1919)" : [ RDS Security Group Rule (p. 1921) object 1, ...
 ],
      "GroupDescription (p. 1919)" : String,
      "Tags" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: AWS::RDS::DBSecurityGroup
Properties:
  EC2VpcId (p. 1918): String
  DBSecurityGroupIngress (p. 1919):
    - RDS Security Group Rule (p. 1921)
  GroupDescription (p. 1919): String
  Tags:
    - Resource Tag
```

Properties

`EC2VpcId`

The Id of the VPC. Indicates which VPC this DB Security Group should belong to.

> **Important**
> The `EC2VpcId` property exists only for backwards compatibility with older regions and is no longer recommended for providing security information to an RDS DB instance. Instead, use `VPCSecurityGroups`.

Type: String

Required: Conditional. Must be specified to create a DB Security Group for a VPC; may not be specified otherwise.

Update requires: Replacement (p. 121)

`DBSecurityGroupIngress`

Network ingress authorization for an Amazon EC2 security group or an IP address range.

Type: List of RDS Security Group Rules (p. 1921).

Required: Yes

Update requires: No interruption (p. 120)

`GroupDescription`

Description of the security group.

Type: String

Required: Yes

Update requires: Replacement (p. 121)

`Tags`

The tags that you want to attach to the Amazon RDS DB security group.

Required: No

Type: A list of resource tags (p. 2258).

Update requires: No interruption (p. 120)

Template Examples

Tip
For more RDS template examples, see Amazon RDS Template Snippets (p. 422).

Single VPC security group

This template snippet creates/updates a single VPC security group, referred to by EC2SecurityGroupName.

JSON

```
"DBSecurityGroup": {
   "Type": "AWS::RDS::DBSecurityGroup",
   "Properties": {
      "EC2VpcId" : { "Ref" : "VpcId" },
      "DBSecurityGroupIngress": [
         {"EC2SecurityGroupName": { "Ref": "WebServerSecurityGroup"}}
      ],
      "GroupDescription": "Frontend Access"
   }
}
```

YAML

```
DBSecurityGroup:
  Type: AWS::RDS::DBSecurityGroup
  Properties:
    EC2VpcId:
```

```
      Ref: "VpcId"
    DBSecurityGroupIngress:
      -
        EC2SecurityGroupName:
          Ref: "WebServerSecurityGroup"
    GroupDescription: "Frontend Access"
```

Multiple VPC security groups

This template snippet creates/updates multiple VPC security groups.

JSON

```
{
   "Resources" : {
      "DBinstance" : {
         "Type" : "AWS::RDS::DBInstance",
         "Properties" : {
            "DBSecurityGroups" : [ {"Ref" : "DbSecurityByEC2SecurityGroup"} ],
            "AllocatedStorage" : "5",
            "DBInstanceClass" : "db.m1.small",
            "Engine" : "MySQL",
            "MasterUsername" : "YourName",
            "MasterUserPassword" : "YourPassword"
         },
         "DeletionPolicy" : "Snapshot"
      },
      "DbSecurityByEC2SecurityGroup" : {
         "Type" : "AWS::RDS::DBSecurityGroup",
         "Properties" : {
            "GroupDescription" : "Ingress for Amazon EC2 security group",
            "DBSecurityGroupIngress" : [ {
                  "EC2SecurityGroupId" : "sg-b0ff1111",
                  "EC2SecurityGroupOwnerId" : "111122223333"
               }, {
                  "EC2SecurityGroupId" : "sg-ffd722222",
                  "EC2SecurityGroupOwnerId" : "111122223333"
               } ]
         }
      }
   }
}
```

YAML

```
Resources:
  DBinstance:
    Type: AWS::RDS::DBInstance
    Properties:
      DBSecurityGroups:
        -
          Ref: "DbSecurityByEC2SecurityGroup"
      AllocatedStorage: "5"
      DBInstanceClass: "db.m1.small"
      Engine: "MySQL"
      MasterUsername: "YourName"
      MasterUserPassword: "YourPassword"
    DeletionPolicy: "Snapshot"
  DbSecurityByEC2SecurityGroup:
    Type: AWS::RDS::DBSecurityGroup
    Properties:
      GroupDescription: "Ingress for Amazon EC2 security group"
```

```
      DBSecurityGroupIngress:
        -
          EC2SecurityGroupId: "sg-b0ff1111"
          EC2SecurityGroupOwnerId: "111122223333"
        -
          EC2SecurityGroupId: "sg-ffd722222"
          EC2SecurityGroupOwnerId: "111122223333"
```

Amazon RDS Security Group Rule

The Amazon RDS security group rule is an embedded property of the AWS::RDS::DBSecurityGroup (p. 1918) type.

Syntax

JSON

```
{
  "CIDRIP (p. 1921)": String,
  "EC2SecurityGroupId (p. 1921)": String,
  "EC2SecurityGroupName (p. 1921)": String,
  "EC2SecurityGroupOwnerId (p. 1922)": String
}
```

YAML

```
CIDRIP (p. 1921): String
EC2SecurityGroupId (p. 1921): String
EC2SecurityGroupName (p. 1921): String
EC2SecurityGroupOwnerId (p. 1922): String
```

Properties

`CIDRIP`

The IP range to authorize.

For an overview of CIDR ranges, go to the Wikipedia Tutorial.

Type: String

Required: No

Update requires: Replacement (p. 121)

`EC2SecurityGroupId`

Id of the VPC or EC2 Security Group to authorize.

For VPC DB Security Groups, use EC2SecurityGroupId. For EC2 Security Groups, use EC2SecurityGroupOwnerId and either EC2SecurityGroupName or EC2SecurityGroupId.

Type: String

Required: No

Update requires: Replacement (p. 121)

`EC2SecurityGroupName`

Name of the EC2 Security Group to authorize.

For VPC DB Security Groups, use EC2SecurityGroupId. For EC2 Security Groups, use EC2SecurityGroupOwnerId and either EC2SecurityGroupName or EC2SecurityGroupId.

Type: String

Required: No

Update requires: Replacement (p. 121)

`EC2SecurityGroupOwnerId`

AWS Account Number of the owner of the EC2 Security Group specified in the EC2SecurityGroupName parameter. The AWS Access Key ID is not an acceptable value.

For VPC DB Security Groups, use EC2SecurityGroupId. For EC2 Security Groups, use EC2SecurityGroupOwnerId and either EC2SecurityGroupName or EC2SecurityGroupId.

Type: String

Required: No

Update requires: Replacement (p. 121)

AWS::RDS::DBSecurityGroupIngress

The AWS::RDS::DBSecurityGroupIngress type enables ingress to a DBSecurityGroup using one of two forms of authorization. First, EC2 or VPC security groups can be added to the DBSecurityGroup if the application using the database is running on EC2 or VPC instances. Second, IP ranges are available if the application accessing your database is running on the Internet. For more information about DB security groups, see Working with DB security groups

This type supports updates. For more information about updating stacks, see AWS CloudFormation Stacks Updates (p. 120).

For details about the settings for DB security group ingress, see AuthorizeDBSecurityGroupIngress.

Topics

- Syntax (p. 1922)
- Properties (p. 1923)
- Return Values (p. 1924)
- See Also (p. 1924)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::RDS::DBSecurityGroupIngress",
  "Properties" : {
   "CIDRIP (p. 1923)": String,
   "DBSecurityGroupName (p. 1923)": String,
   "EC2SecurityGroupId (p. 1923)": String,
   "EC2SecurityGroupName (p. 1923)": String,
   "EC2SecurityGroupOwnerId (p. 1923)": String
}
```

YAML

```
Type: "AWS::RDS::DBSecurityGroupIngress"
Properties:
  CIDRIP (p. 1923): String
  DBSecurityGroupName (p. 1923): String
  EC2SecurityGroupId (p. 1923): String
  EC2SecurityGroupName (p. 1923): String
  EC2SecurityGroupOwnerId (p. 1923): String
```

Properties

`CIDRIP`

The IP range to authorize.

For an overview of CIDR ranges, go to the Wikipedia Tutorial.

Type: String

Update requires: No interruption (p. 120)

`DBSecurityGroupName`

The name (ARN) of the AWS::RDS::DBSecurityGroup (p. 1918) to which this ingress will be added.

Type: String

Required: Yes

Update requires: No interruption (p. 120)

`EC2SecurityGroupId`

The ID of the VPC or EC2 security group to authorize.

For VPC DB security groups, use EC2SecurityGroupId. For EC2 security groups, use EC2SecurityGroupOwnerId and either EC2SecurityGroupName or EC2SecurityGroupId.

Type: String

Required: No

Update requires: No interruption (p. 120)

`EC2SecurityGroupName`

The name of the EC2 security group to authorize.

For VPC DB security groups, use EC2SecurityGroupId. For EC2 security groups, use EC2SecurityGroupOwnerId and either EC2SecurityGroupName or EC2SecurityGroupId.

Type: String

Required: No

Update requires: No interruption (p. 120)

`EC2SecurityGroupOwnerId`

The AWS Account Number of the owner of the EC2 security group specified in the EC2SecurityGroupName parameter. The AWS Access Key ID is not an acceptable value.

For VPC DB security groups, use EC2SecurityGroupId. For EC2 security groups, use EC2SecurityGroupOwnerId and either EC2SecurityGroupName or EC2SecurityGroupId.

Type: String

Required: No

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

See Also

- AuthorizeDBSecurityGroupIngress in the *Amazon Relational Database Service API Reference*

AWS::RDS::DBSubnetGroup

The AWS::RDS::DBSubnetGroup type creates an RDS database subnet group. Subnet groups must contain at least two subnets in two different Availability Zones in the same region.

Topics

- Syntax (p. 1924)
- Properties (p. 1925)
- Return Value (p. 1925)
- Example (p. 1926)
- See Also (p. 1926)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::RDS::DBSubnetGroup",
   "Properties" : {
      "DBSubnetGroupDescription (p. 1925)" : String,
      "DBSubnetGroupName (p. 1925)" : String,
      "SubnetIds (p. 1925)" : [ String, ... ],
      "Tags" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: "AWS::RDS::DBSubnetGroup"
```

```
Properties:
  DBSubnetGroupDescription (p. 1925): String
  DBSubnetGroupName (p. 1925): String
  SubnetIds (p. 1925):
    - String
  Tags:
    - Resource Tag
```

Properties

`DBSubnetGroupDescription`

The description for the DB Subnet Group.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`DBSubnetGroupName`

The name for the DB Subnet Group. This value is stored as a lowercase string.

Constraints: Must contain no more than 255 letters, numbers, periods, underscores, spaces, or hyphens. Must not be default.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SubnetIds`

The EC2 Subnet IDs for the DB Subnet Group.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`Tags`

The tags that you want to attach to the RDS database subnet group.

Required: No

Type: A list of resource tags (p. 2258) in key-value format.

Update requires: No interruption (p. 120)

Return Value

Ref

When you pass the logical ID of an `AWS::RDS::DBSubnetGroup` resource to the intrinsic `Ref` function, the function returns the name of the DB subnet group, such as `mystack-mydbsubnetgroup-0a12bc456789de0fg`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "myDBSubnetGroup" : {
         "Type" : "AWS::RDS::DBSubnetGroup",
         "Properties" : {
            "DBSubnetGroupDescription" : "description",
            "SubnetIds" : [ "subnet-7b5b4112", "subnet-7b5b4115" ],
            "Tags" : [ {"Key" : "String", "Value" : "String"} ]
         }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  myDBSubnetGroup:
    Type: "AWS::RDS::DBSubnetGroup"
    Properties:
      DBSubnetGroupDescription: "description"
      SubnetIds:
        - "subnet-7b5b4112"
        - "subnet-7b5b4115"
      Tags:
        -
          Key: "String"
          Value: "String"
```

AWS::RDS::EventSubscription

Use the `AWS::RDS::EventSubscription` resource to get notifications for Amazon Relational Database Service events through the Amazon Simple Notification Service. For more information, see Using Amazon RDS Event Notification in the *Amazon RDS User Guide*.

Topics

- Syntax (p. 1926)
- Properties (p. 1927)
- Return Value (p. 1928)
- Example (p. 1928)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::RDS::EventSubscription",
  "Properties" : {
    "Enabled" : Boolean,
    "EventCategories" : [ String, ... ],
    "SnsTopicArn" : String,
    "SourceIds" : [ String, ... ],
    "SourceType" : String
  }
}
```

YAML

```
Type: "AWS::RDS::EventSubscription"
Properties:
  Enabled: Boolean
  EventCategories:
    - String
  SnsTopicArn: String
  SourceIds:
    - String
  SourceType: String
```

Properties

`Enabled`

Indicates whether to activate the subscription. If you don't specify this property, AWS CloudFormation activates the subscription.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`EventCategories`

A list of event categories that you want to subscribe to for a given source type. If you don't specify this property, you are notified about all event categories. For more information, see Using Amazon RDS Event Notification in the *Amazon RDS User Guide*.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SnsTopicArn`

The Amazon Resource Name (ARN) of an Amazon SNS topic that you want to send event notifications to.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SourceIds`

A list of identifiers for which Amazon RDS provides notification events.

If you don't specify a value, notifications are provided for all sources. If you specify multiple values, they must be of the same type. For example, if you specify a database instance ID, all other values must be database instance IDs.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`SourceType`

The type of source for which Amazon RDS provides notification events. For example, if you want to be notified of events generated by a database instance, set this parameter to `db-instance`. If you don't specify a value, notifications are provided for all source types. For valid values, see the `SourceType` parameter for the CreateEventSubscription action in the *Amazon RDS API Reference*.

Required: Conditional. If you specify the `SourceIds` or `EventCategories` property, you must specify this property.

Type: String

Update requires: Replacement (p. 121) if you're removing this property after it was previously specified. All other updates require no interruption (p. 120).

Return Value

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myEventSubscription" }
```

For the resource with the logical ID `myEventSubscription`, `Ref` returns the Amazon RDS event subscription name, such as: `mystack-myEventSubscription-1DDYF1E3B3I`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following snippet creates an event subscription for an existing database instance `db-instance-1` and a database with the logical ID `myDBInstance`, which is declared elsewhere in the same template.

JSON

```
"myEventSubscription": {
  "Type": "AWS::RDS::EventSubscription",
  "Properties": {
    "EventCategories": ["configuration change", "failure", "deletion"],
    "SnsTopicArn": "arn:aws:sns:us-west-2:123456789012:example-topic",
    "SourceIds": ["db-instance-1", { "Ref" : "myDBInstance" }],
    "SourceType":"db-instance",
    "Enabled" : false
  }
}
```

YAML

```
myEventSubscription:
  Type: "AWS::RDS::EventSubscription"
  Properties:
    EventCategories:
      - "configuration change"
      - "failure"
      - "deletion"
    SnsTopicArn: "arn:aws:sns:us-west-2:123456789012:example-topic"
    SourceIds:
      - "db-instance-1"
      -
        Ref: "myDBInstance"
    SourceType: "db-instance"
    Enabled: false
```

AWS::RDS::OptionGroup

Use the `AWS::RDS::OptionGroup` resource to create an option group that can make managing data and databases easier. For more information about option groups, see Working with Option Groups in the *Amazon Relational Database Service User Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::RDS::OptionGroup",
   "Properties" : {
      "EngineName" : String,
      "MajorEngineVersion" : String,
      "OptionGroupDescription" : String,
      "OptionConfigurations" : [ OptionConfiguration, ... ],
      "Tags" : [ Resource Tag, ... ]
   }
}
```

YAML

```
Type: "AWS::RDS::OptionGroup"
Properties:
  EngineName: String
  MajorEngineVersion: String
  OptionGroupDescription: String
  OptionConfigurations:
    - OptionConfiguration
  Tags:
    - Resource Tag
```

Properties

`EngineName`

The name of the database engine that this option group is associated with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`MajorEngineVersion`

The major version number of the database engine that this option group is associated with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`OptionGroupDescription`

A description of the option group.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`OptionConfigurations`

The configurations for this option group.

Required: Yes

Type: List of OptionConfiguration (p. 1932)

Update requires: Replacement (p. 121)

`Tags`

An arbitrary set of tags (key–value pairs) for this option group.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myOptionGroup" }
```

For the `myOptionGroup` resource, `Ref` returns the name of the option group.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Multiple Option Configurations

The following snippet creates an option group with two option configurations (`OEM` and `APEX`):

JSON

```
"OracleOptionGroup": {
  "Type": "AWS::RDS::OptionGroup",
  "Properties": {
    "EngineName": "oracle-ee",
    "MajorEngineVersion": "12.1",
    "OptionGroupDescription": "A test option group",
    "OptionConfigurations":[
      {
        "OptionName": "OEM",
        "DBSecurityGroupMemberships": ["default"],
        "Port": "5500"
      },
      {
        "OptionName": "APEX"
      }
    ]
  }
}
```

YAML

```
OracleOptionGroup:
  Type: "AWS::RDS::OptionGroup"
  Properties:
    EngineName: "oracle-ee"
    MajorEngineVersion: "12.1"
    OptionGroupDescription: "A test option group"
    OptionConfigurations:
      -
        OptionName: "OEM"
        DBSecurityGroupMemberships:
          - "default"
        Port: "5500"
      -
        OptionName: "APEX"
```

Multiple Settings

The following snippet creates an option group that specifies two option settings for the `MEMCACHED` option:

JSON

```
"SQLOptionGroup": {
  "Type": "AWS::RDS::OptionGroup",
  "Properties": {
    "EngineName": "mysql",
    "MajorEngineVersion": "5.6",
    "OptionGroupDescription": "A test option group",
    "OptionConfigurations":[
      {
        "OptionName": "MEMCACHED",
        "VpcSecurityGroupMemberships": ["sg-a1238db7"],
        "Port": "1234",
        "OptionSettings": [
          {"Name": "CHUNK_SIZE", "Value": "32"},
          {"Name": "BINDING_PROTOCOL", "Value": "ascii"}
        ]
      }
    ]
```

```
  }
}
```

YAML

```
SQLOptionGroup:
  Type: 'AWS::RDS::OptionGroup'
  Properties:
    EngineName: mysql
    MajorEngineVersion: '5.6'
    OptionGroupDescription: A test option group
    OptionConfigurations:
      - OptionName: MEMCACHED
        VpcSecurityGroupMemberships:
          - sg-a1238db7
        Port: '1234'
        OptionSettings:
          - Name: CHUNK_SIZE
            Value: '32'
          - Name: BINDING_PROTOCOL
            Value: ascii
```

Amazon Relational Database Service OptionGroup OptionConfiguration

Use the `OptionConfigurations` property to configure an option and its settings for an AWS::RDS::OptionGroup (p. 1929) resource.

Syntax

JSON

```
{
  "DBSecurityGroupMemberships" : [ String, ... ],
  "OptionName" : String,
  "OptionSettings" : [ OptionSetting, ... ],
  "OptionVersion" : String,
  "Port" : Integer,
  "VpcSecurityGroupMemberships" : [ String, ... ]
}
```

YAML

```
DBSecurityGroupMemberships:
  - String
OptionName: String
OptionSettings:
  - OptionSetting
OptionVersion: String
Port: Integer
VpcSecurityGroupMemberships:
  - String
```

Properties

`DBSecurityGroupMemberships`

A list of database security group names for this option. If the option requires access to a port, the security groups must allow access to that port. If you specify this property, don't specify the `VPCSecurityGroupMemberships` property.

Required: No

Type: List of String values

`OptionName`

The name of the option. For more information about options, see Working with Option Groups in the *Amazon Relational Database Service User Guide*.

Required: Yes

Type: String

`OptionSettings`

The settings for this option.

Required: No

Type: List of OptionSetting (p. 1934)

`OptionVersion`

The version for the option.

Required: No

Type: String

`Port`

The port number that this option uses.

Required: No

Type: Integer

`VpcSecurityGroupMemberships`

A list of VPC security group IDs for this option. If the option requires access to a port, the security groups must allow access to that port. If you specify this property, don't specify the `DBSecurityGroupMemberships` property.

Required: No

Type: List of String values

Examples

The following example template uses `OptionName` and `OptionVersion` parameters when creating an `AWS::RDS::OptionGroup` resource.

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Description":"APEX has a dependency on XMLDB, so, there must be at least one XMLDB when
 there is an APEX",
  "Parameters" : {
    "OptionName" : {
      "Type" : "String"
    },
    "OptionVersion" : {
      "Type" : "String"
```

```
    }
  },
  "Resources": {
    "myOptionGroup": {
      "Type": "AWS::RDS::OptionGroup",
      "Properties": {
        "EngineName": "oracle-ee",
        "MajorEngineVersion": "11.2",
        "OptionGroupDescription": "testing creating optionGroup with APEX version",
        "OptionConfigurations":[
          {
            "OptionName": "XMLDB"
          },
          {
            "OptionName": {"Ref" : "OptionName"},
            "OptionVersion" : {"Ref" : "OptionVersion"}
          }
        ]
      }
    }
  }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Description: >-
  APEX has a dependency on XMLDB, so, there must be at least one XMLDB when
  there is an APEX
Parameters:
  OptionName:
    Type: String
  OptionVersion:
    Type: String
Resources:
  myOptionGroup:
    Type: AWS::RDS::OptionGroup
    Properties:
      EngineName: oracle-ee
      MajorEngineVersion: '11.2'
      OptionGroupDescription: testing creating optionGroup with APEX version
      OptionConfigurations:
        - OptionName: XMLDB
        - OptionName: !Ref OptionName
          OptionVersion: !Ref OptionVersion
```

See Also

Amazon Relational Database Service OptionGroup OptionSetting

Use the `OptionSettings` property to specify settings for an option in the `OptionConfigurations` (p. 1932) property.

Syntax

JSON

```
{
```

```
  "Name" : String,
  "Value" : String
}
```

YAML

```
Name: String
Value: String
```

Properties

`Name`

The name of the option setting that you want to specify.

Required: No

Type: String

`Value`

The value of the option setting.

Required: No

Type: String

See Also

- Working with Option Groups in the *Amazon RDS User Guide*

Amazon Redshift Resource Types Reference

This section contains reference information for all Amazon Redshift resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::Redshift::data-type-name
```

Topics

- AWS::Redshift::Cluster (p. 1935)
- AWS::Redshift::ClusterParameterGroup (p. 1944)
- AWS::Redshift::ClusterSecurityGroup (p. 1947)
- AWS::Redshift::ClusterSecurityGroupIngress (p. 1949)
- AWS::Redshift::ClusterSubnetGroup (p. 1951)

AWS::Redshift::Cluster

Use the `AWS::Redshift::Cluster` resource to create an Amazon Redshift cluster. A *cluster* is a fully managed data warehouse that consists of a set of compute nodes. For more information about default and valid values, see CreateCluster in the *Amazon Redshift API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Redshift::Cluster",
  "Properties" : {
    "AllowVersionUpgrade" : Boolean,
    "AutomatedSnapshotRetentionPeriod" : Integer,
    "AvailabilityZone" : String,
    "ClusterIdentifier" : String,
    "ClusterParameterGroupName" : String,
    "ClusterSecurityGroups" : [ String, ... ],
    "ClusterSubnetGroupName" : String,
    "ClusterType" : String,
    "ClusterVersion" : String,
    "DBName" : String,
    "ElasticIp" : String,
    "Encrypted" : Boolean,
    "HsmClientCertificateIdentifier" : String,
    "HsmConfigurationIdentifier" : String,
    "IamRoles" : [ String, ... ],
    "KmsKeyId" : String,
    "LoggingProperties" :  LoggingProperties (p. 1943),
    "MasterUsername" : String,
    "MasterUserPassword" : String,
    "NodeType" : String,
    "NumberOfNodes" : Integer,
    "OwnerAccount" : String,
    "Port" : Integer,
    "PreferredMaintenanceWindow" : String,
    "PubliclyAccessible" : Boolean,
    "SnapshotClusterIdentifier" : String,
    "SnapshotIdentifier" : String,
    "Tags" : [ Resource Tag, ... ],
    "VpcSecurityGroupIds" : [ String, ... ]
  }
}
```

YAML

```
Type: "AWS::Redshift::Cluster"
Properties:
  AllowVersionUpgrade: Boolean
  AutomatedSnapshotRetentionPeriod: Integer
  AvailabilityZone: String
  ClusterIdentifier: String
  ClusterParameterGroupName: String
  ClusterSecurityGroups:
    - String
  ClusterSubnetGroupName: String
  ClusterType: String
  ClusterVersion: String
  DBName: String
  ElasticIp: String
  Encrypted: Boolean
  HsmClientCertificateIdentifier: String
  HsmConfigurationIdentifier: String
  IamRoles:
    - String
  KmsKeyId: String
```

```
  LoggingProperties:
     LoggingProperties (p. 1943)
  MasterUsername: String
  MasterUserPassword: String
  NodeType: String
  NumberOfNodes: Integer
  OwnerAccount: String
  Port: Integer
  PreferredMaintenanceWindow: String
  PubliclyAccessible: Boolean
  SnapshotClusterIdentifier: String
  SnapshotIdentifier: String
  Tags:
    - Resource Tag
  VpcSecurityGroupIds:
    - String
```

Properties

For more information about each property, including constraints and valid values, see CreateCluster in the *Amazon Redshift API Reference*.

`AllowVersionUpgrade`

When a new version of Amazon Redshift is released, tells whether upgrades can be applied to the engine that is running on the cluster. The upgrades are applied during the maintenance window. The default value is `true`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`AutomatedSnapshotRetentionPeriod`

The number of days that automated snapshots are retained. The default value is `1`. To disable automated snapshots, set the value to `0`.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`AvailabilityZone`

The Amazon Elastic Compute Cloud (Amazon EC2) Availability Zone in which you want to provision your Amazon Redshift cluster. For example, if you have several EC2 instances running in a specific Availability Zone, you might want the cluster to be provisioned in the same zone to decrease network latency.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ClusterIdentifier`

The unique identifier of the cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ClusterParameterGroupName`

The name of the parameter group that you want to associate with this cluster.

Required: No

Type: String

Update requires: Some interruptions (p. 121)

`ClusterSecurityGroups`

A list of security groups that you want to associate with this cluster. Applies to EC2-Classic.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`ClusterSubnetGroupName`

The name of a cluster subnet group that you want to associate with this cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ClusterType`

The type of cluster. Specify `single-node` or `multi-node` (default).

Required: Yes

Type: String

Update requires: Some interruptions (p. 121)

`ClusterVersion`

The version of the Amazon Redshift engine that you want to deploy on the cluster.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DBName`

The name of the first database that will be created when the cluster is created.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ElasticIp`

The Elastic IP (EIP) address for the cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Encrypted`

Indicates whether the data in the cluster is encrypted at rest. The default value is `false`.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`HsmClientCertificateIdentifier`

Specifies the name of the hardware security module (HSM) client certificate that the Amazon Redshift cluster uses to retrieve the data encryption keys stored in an HSM.

Required: No

Type: String

Update requires: No interruption (p. 120)

`HsmConfigurationIdentifier`

The name of the HSM configuration that contains the information that the Amazon Redshift cluster can use to retrieve and store keys in an HSM.

Required: No

Type: String

Update requires: No interruption (p. 120)

`IamRoles`

A list of AWS Identity and Access Management (IAM) roles that the cluster can use to access other AWS services. Supply the IAM roles by their Amazon Resource Name (ARN). You can provide a maximum of 10 IAM roles in a single request. A cluster can have a maximum of 10 IAM roles associated with it at a time.

Required: No

Type: String

Update requires: No interruption (p. 120)

`KmsKeyId`

The ID of the AWS Key Management Service (AWS KMS) key that you want to use to encrypt data in the cluster.

Required: No

Type: String

Update requires: Replacement (p. 121)

`LoggingProperties`

Configures Amazon Redshift to create audit log files, containing logging information such as queries and connection attempts, for this cluster.

Required: No

Type: Amazon Redshift LoggingProperties (p. 1943)

Update requires: No interruption (p. 120)

`MasterUsername`

The user name that is associated with the master user account for this cluster.

You must specify values for `MasterUserName` and `MasterUserPassword`. However, if you're restoring from an Amazon Redshift snapshot, AWS CloudFormation ignores the specified values and uses the values that are stored in the snapshot.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`MasterUserPassword`

The password associated with the master user account for this cluster.

You must specify values for `MasterUserName` and `MasterUserPassword`. However, if you're restoring from an Amazon Redshift snapshot, AWS CloudFormation ignores the specified values and uses the values that are stored in the snapshot.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`NodeType`

The node type that is provisioned for this cluster.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`NumberOfNodes`

The number of compute nodes in the cluster. If you specify `multi-node` for the `ClusterType` parameter, you must specify a number greater than `1`.

> **Important**
> You can't specify this parameter for a single-node cluster.

Required: Conditional

Type: Integer

Update requires: Some interruptions (p. 121)

`OwnerAccount`

When you restore from a snapshot from another AWS account, the 12-digit AWS account ID that contains that snapshot.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Port`

The port number on which the cluster accepts incoming connections. The default value is `5439`.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`PreferredMaintenanceWindow`

The weekly time range (in UTC) during which automated cluster maintenance can occur. The format of the time range is `ddd:hh24:mi-ddd:hh24:mi`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PubliclyAccessible`

Indicates whether the cluster can be accessed from a public network.

Required: No

Type: Boolean

Update requires: Some interruptions (p. 121)

`SnapshotClusterIdentifier`

The name of the cluster that the source snapshot was created from. For more information about restoring from a snapshot, see the RestoreFromClusterSnapshot action in the *Amazon Redshift API Reference*.

Required: No

Required: Conditional. This property is required if your IAM policy includes a restriction on the cluster name and the resource element specifies anything other than the wildcard character (`*`) for the cluster name.

Update requires: Replacement (p. 121)

`SnapshotIdentifier`

The name of the snapshot from which to create a new cluster.

Required: Conditional. If you specified the `SnapshotClusterIdentifier` property, you must specify this property.

Type: String

Update requires: Replacement (p. 121)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this cluster. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`VpcSecurityGroupIds`

A list of VPC security groups that are associated with this cluster.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myCluster" }
```

For the Amazon Redshift cluster `myCluster`, `Ref` returns the name of the cluster.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Endpoint.Address`

The connection endpoint for the Amazon Redshift cluster. For example: `examplecluster.cg034hpkmmjt.us-east-1.redshift.amazonaws.com`.

`Endpoint.Port`

The port number on which the Amazon Redshift cluster accepts connections. For example: `5439`.

Example

The following example describes a single-node Amazon Redshift cluster. The master user password is referenced from an input parameter that is in the same template.

JSON

```
"myCluster": {
  "Type": "AWS::Redshift::Cluster",
  "Properties": {
    "DBName": "mydb",
    "MasterUsername": "master",
    "MasterUserPassword": { "Ref" : "MasterUserPassword" },
    "NodeType": "ds2.xlarge",
    "ClusterType": "single-node",
    "Tags": [
      {
        "Key": "foo",
        "Value": "bar"
      }
    ]
  }
}
```

YAML

```
myCluster:
  Type: "AWS::Redshift::Cluster"
  Properties:
    DBName: "mydb"
    MasterUsername: "master"
    MasterUserPassword:
      Ref: "MasterUserPassword"
    NodeType: "ds2.xlarge"
    ClusterType: "single-node"
    Tags:
      - Key: foo
        Value: bar
```

More Info

For a complete example template, see Amazon Redshift Template Snippets (p. 416).

Amazon Redshift LoggingProperties

Use the `LoggingProperties` property of the AWS::Redshift::Cluster (p. 1935) resource to configure audit log files, containing information such as queries and connection attempts, for the cluster.

Syntax

JSON

```
{
  "BucketName" : String,
  "S3KeyPrefix" : String
}
```

YAML

```
BucketName: String
S3KeyPrefix: String
```

Properties

For more information and property constraints, see EnableLogging in the *Amazon Redshift API Reference*.

`BucketName`

The name of an existing S3 bucket where the log files are to be stored.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`S3KeyPrefix`

The prefix applied to the log file names.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS::Redshift::ClusterParameterGroup

Creates an Amazon Redshift parameter group that you can associate with an Amazon Redshift cluster. The parameters in the group apply to all the databases that you create in the cluster.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Redshift::ClusterParameterGroup",
  "Properties" : {
    "Description" : String,
    "ParameterGroupFamily" : String,
    "Parameters" : [ Parameter, ... ],
    "Tags" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: "AWS::Redshift::ClusterParameterGroup"
Properties:
  Description: String
  ParameterGroupFamily: String
  Parameters:
    - Parameter
  Tags:
    - Resource Tag
```

Properties

`Description`

A description of the parameter group.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ParameterGroupFamily`

The Amazon Redshift engine version that applies to this cluster parameter group. The cluster engine version determines the set of parameters that you can specify in the `Parameters` property.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Parameters`

A list of parameter names and values that are allowed by the Amazon Redshift engine version that you specified in the `ParameterGroupFamily` property. For more information, see Amazon Redshift Parameter Groups in the *Amazon Redshift Cluster Management Guide*.

Required: No

Type: Amazon Redshift Parameter Type (p. 1946)

Update requires: No interruption (p. 120)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this parameter group. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myClusterParameterGroup" }
```

For the Amazon Redshift cluster parameter group `myClusterParameterGroup`, `Ref` returns the name of the cluster parameter group.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Single Parameter

The following example describes a parameter group with one parameter that is specified:

JSON

```
"myClusterParameterGroup" : {
  "Type" : "AWS::Redshift::ClusterParameterGroup",
  "Properties" : {
    "Description" : "My parameter group",
    "ParameterGroupFamily" : "redshift-1.0",
    "Parameters" : [ {
      "ParameterName" : "enable_user_activity_logging",
      "ParameterValue" : "true"
    }]
  }
}
```

YAML

```
myClusterParameterGroup:
  Type: "AWS::Redshift::ClusterParameterGroup"
  Properties:
    Description: "My parameter group"
    ParameterGroupFamily: "redshift-1.0"
```

```
    Parameters:
      -
        ParameterName: "enable_user_activity_logging"
        ParameterValue: "true"
```

Workload Management Configuration

The following example modifies the workload management configuration using the `wlm_json_configuration` parameter. The parameter value is a JSON object that must be passed as a string enclosed in quotation marks (`"`).

JSON

```
"RedshiftClusterParameterGroup": {
  "Type": "AWS::Redshift::ClusterParameterGroup",
  "Properties": {
    "Description": "Cluster parameter group",
    "ParameterGroupFamily": "redshift-1.0",
    "Parameters": [{
      "ParameterName": "wlm_json_configuration",
      "ParameterValue": "[{\"user_group\":[\"example_user_group1\"],\"query_group\":
[\"example_query_group1\"],\"query_concurrency\":7},{\"query_concurrency\":5}]"
    }],
    "Tags": [
      {
        "Key": "foo",
        "Value": "bar"
      }
    ]
  }
}
```

YAML

```
RedshiftClusterParameterGroup:
  Type: "AWS::Redshift::ClusterParameterGroup"
  Properties:
    Description: "Cluster parameter group"
    ParameterGroupFamily: "redshift-1.0"
    Parameters:
      -
        ParameterName: "wlm_json_configuration"
        ParameterValue: "[{\"user_group\":[\"example_user_group1\"],\"query_group\":
[\"example_query_group1\"],\"query_concurrency\":7},{\"query_concurrency\":5}]"
    Tags:
      - Key: foo
        Value: bar
```

Amazon Redshift Parameter Type

Describes parameters for the AWS::Redshift::ClusterParameterGroup (p. 1944) resource type.

Syntax

JSON

```
{
  "ParameterName" : String,
  "ParameterValue" : String
}
```

YAML

```
ParameterName: String
ParameterValue: String
```

Properties

`ParameterName`

The name of the parameter.

Required: Yes

Type: String

`ParameterValue`

The value of the parameter.

Required: Yes

Type: String

AWS::Redshift::ClusterSecurityGroup

Creates an Amazon Redshift security group. You use security groups to control access to Amazon Redshift clusters that are not in a VPC.

Topics

- Syntax (p. 1947)
- Properties (p. 1948)
- Return Values (p. 1948)
- Example (p. 1948)
- See Also (p. 1949)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Redshift::ClusterSecurityGroup",
  "Properties" : {
    "Description" : String,
    "Tags" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: "AWS::Redshift::ClusterSecurityGroup"
Properties:
  Description: String
  Tags:
```

```
    - Resource Tag
```

Properties

`Description`

A description of the security group.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this security group. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myClusterSecurityGroup" }
```

For the Amazon Redshift cluster security group `myClusterSecurityGroup`, `Ref` returns the name of the cluster security group.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates an Amazon Redshift cluster security group that you can associate cluster security group ingress rules with:

JSON

```
"myClusterSecurityGroup": {
  "Type": "AWS::Redshift::ClusterSecurityGroup",
  "Properties": {
    "Description": "Security group to determine where connections to the Amazon Redshift
 cluster can come from",
    "Tags": [
      {
        "Key": "foo",
        "Value": "bar"
      }
    ]
  }
}
```

YAML

```
myClusterSecurityGroup:
  Type: "AWS::Redshift::ClusterSecurityGroup"
  Properties:
    Description: "Security group to determine where connections to the Amazon Redshift
 cluster can come from"
    Tags:
      - Key: foo
        Value: bar
```

See Also

- AWS::Redshift::ClusterSecurityGroupIngress (p. 1949)

AWS::Redshift::ClusterSecurityGroupIngress

Specifies inbound (ingress) rules for an Amazon Redshift security group.

Topics

- Syntax (p. 1949)
- Properties (p. 1949)
- Template Snippet (p. 1950)
- See Also (p. 1951)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Redshift::ClusterSecurityGroupIngress",
  "Properties" : {
    "ClusterSecurityGroupName" : String,
    "CIDRIP" : String,
    "EC2SecurityGroupName" : String,
    "EC2SecurityGroupOwnerId" : String
  }
}
```

YAML

```
Type: "AWS::Redshift::ClusterSecurityGroupIngress"
Properties:
  ClusterSecurityGroupName: String
  CIDRIP: String
  EC2SecurityGroupName: String
  EC2SecurityGroupOwnerId: String
```

Properties

`ClusterSecurityGroupName`

The name of the Amazon Redshift security group that will be associated with the ingress rule.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`CIDRIP`

The IP address range that has inbound access to the Amazon Redshift security group.

Required: No

Type: String

Update requires: Replacement (p. 121)

`EC2SecurityGroupName`

The Amazon EC2 security group that will be added the Amazon Redshift security group.

Required: No

Type: String

Update requires: Replacement (p. 121)

`EC2SecurityGroupOwnerId`

The 12-digit AWS account number of the owner of the Amazon EC2 security group that is specified by the `EC2SecurityGroupName` parameter.

Required: Conditional. If you specify the `EC2SecurityGroupName` property, you must specify this property.

Type: String

Update requires: Replacement (p. 121)

Template Snippet

The following snippet describes a ingress rules for an Amazon Redshift cluster security group:

JSON

```
"myClusterSecurityGroupIngressIP" : {
  "Type": "AWS::Redshift::ClusterSecurityGroupIngress",
  "Properties": {
    "ClusterSecurityGroupName" : {"Ref":"myClusterSecurityGroup"},
    "CIDRIP" : "10.0.0.0/16"
  }
}
```

YAML

```
myClusterSecurityGroupIngressIP:
  Type: "AWS::Redshift::ClusterSecurityGroupIngress"
  Properties:
    ClusterSecurityGroupName:
      Ref: "myClusterSecurityGroup"
    CIDRIP: "10.0.0.0/16"
```

See Also

- AWS::Redshift::ClusterSecurityGroup (p. 1947)

AWS::Redshift::ClusterSubnetGroup

Creates an Amazon Redshift subnet group. You must provide a list of one or more subnets in your existing Amazon VPC when creating an Amazon Redshift subnet group.

Topics

- Syntax (p. 1951)
- Properties (p. 1951)
- Return Values (p. 1952)
- Example (p. 1952)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Redshift::ClusterSubnetGroup",
  "Properties" : {
    "Description" : String,
    "SubnetIds" : [ String, ... ],
    "Tags" : [ Resource Tag, ... ]
  }
}
```

YAML

```
Type: "AWS::Redshift::ClusterSubnetGroup"
Properties:
  Description: String
  SubnetIds:
    - String
  Tags:
    - Resource Tag
```

Properties

`Description`

A description of the subnet group.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`SubnetIds`

A list of VPC subnet IDs. You can modify a maximum of 20 subnets.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`Tags`

Specifies an arbitrary set of tags (key–value pairs) to associate with this subnet group. Use tags to manage your resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myClusterSubnetGroup" }
```

For the Amazon Redshift cluster subnet group `myClusterSubnetGroup`, `Ref` returns the name of the cluster subnet group.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example specifies one subnet for an Amazon Redshift cluster subnet group.

JSON

```
"myClusterSubnetGroup": {
  "Type": "AWS::Redshift::ClusterSubnetGroup",
  "Properties": {
    "Description": "My ClusterSubnetGroup",
    "SubnetIds": [
      "subnet-7fbc2813"
    ],
    "Tags": [
      {
        "Key": "foo",
        "Value": "bar"
      }
    ]
  }
}
```

YAML

```
myClusterSubnetGroup:
  Type: 'AWS::Redshift::ClusterSubnetGroup'
  Properties:
    Description: My ClusterSubnetGroup
    SubnetIds:
      - subnet-7fbc2813
```

```
    Tags:
      - Key: foo
        Value: bar
```

Amazon Route 53 Resource Types Reference

This section contains reference information for all Amazon Route 53 resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form for Route 53 resources:

```
AWS::Route53::data-type-name
```

And the following form for Route 53 service discovery resources:

```
AWS::Route53::data-type-name
```

Topics

- AWS::ServiceDiscovery::PublicDnsNamespace (p. 1978)
- AWS::ServiceDiscovery::Service (p. 1979)

AWS::Route53::HealthCheck

Use the `AWS::Route53::HealthCheck` resource to check the health of your resources before Amazon Route 53 responds to a DNS query. For more information, see How Health Checks Work in Simple Amazon Route 53 Configurations in the *Amazon Route 53 Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Route53::HealthCheck",
  "Properties" : {
    "HealthCheckConfig" : HealthCheckConfig,
    "HealthCheckTags" : [ HealthCheckTags, ... ]
  }
}
```

YAML

```
Type: "AWS::Route53::HealthCheck"
Properties:
```

```
  HealthCheckConfig:
    HealthCheckConfig
  HealthCheckTags:
    - HealthCheckTags
```

Properties

`HealthCheckConfig`

An Amazon Route 53 health check.

Required: Yes

Type: Route 53 HealthCheck HealthCheckConfig (p. 1956)

Update requires: No interruption (p. 120)

`HealthCheckTags`

An arbitrary set of tags (key–value pairs) for this health check.

Required: No

Type: A list of Amazon Route 53 HealthCheck HealthCheckTags (p. 1959)

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the health check ID, such as `e0a123b4-4dba-4650-935e-example`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates an Amazon Route 53 health check that sends request to the specified endpoint.

JSON

```
"myHealthCheck": {
  "Type": "AWS::Route53::HealthCheck",
  "Properties": {
    "HealthCheckConfig": {
      "IPAddress": "000.000.000.000",
      "Port": "80",
      "Type": "HTTP",
      "ResourcePath": "/example/index.html",
      "FullyQualifiedDomainName": "example.com",
      "RequestInterval": "30",
      "FailureThreshold": "3"
    },
    "HealthCheckTags" : [{
      "Key": "SampleKey1",
      "Value": "SampleValue1"
    },
    {
      "Key": "SampleKey2",
```

```
      "Value": "SampleValue2"
    }]
  }
}
```

YAML

```
myHealthCheck:
  Type: "AWS::Route53::HealthCheck"
  Properties:
    HealthCheckConfig:
      IPAddress: "000.000.000.000"
      Port: "80"
      Type: "HTTP"
      ResourcePath: "/example/index.html"
      FullyQualifiedDomainName: "example.com"
      RequestInterval: "30"
      FailureThreshold: "3"
    HealthCheckTags:
      -
        Key: "SampleKey1"
        Value: "SampleValue1"
      -
        Key: "SampleKey2"
        Value: "SampleValue2"
```

Amazon Route 53 HealthCheck AlarmIdentifier

The `AlarmIdentifier` subproperty describes the name and Region that are associated with an Route 53 HealthCheck HealthCheckConfig (p. 1956) property.

Syntax

JSON

```
{
  "Name" : String,
  "Region" : String
}
```

YAML

```
Name: String
Region: String
```

Properties

`Name`

The name of the Amazon CloudWatch alarm that you want Route 53 health checkers to use to determine whether this health check is healthy.

Required: Yes

Type: String

`Region`

A complex type that identifies the CloudWatch alarm that you want Route 53 health checkers to use to determine whether this health check is healthy. For example, `us-west-2`.

Required: Yes

Type: String

Route 53 HealthCheck HealthCheckConfig

The `HealthCheckConfig` property is part of the AWS::Route53::HealthCheck (p. 1953) resource that describes a health check that Amazon Route 53 uses before responding to a DNS query. For more information, see HealthCheckConfig in the *Amazon Route 53 API Reference*

Syntax

JSON

```
{
  "AlarmIdentifier" : AlarmIdentifier,
  "ChildHealthChecks" : [ String, ... ],
  "EnableSNI" : Boolean,
  "FailureThreshold" : Integer,
  "FullyQualifiedDomainName" : String,
  "HealthThreshold" : Integer,
  "InsufficientDataHealthStatus" : String,
  "Inverted" : Boolean,
  "IPAddress" : String,
  "MeasureLatency" : Boolean,
  "Port" : Integer,
  "Regions" : [ String, ... ],
  "RequestInterval" : Integer,
  "ResourcePath" : String,
  "SearchString" : String,
  "Type" : String
}
```

YAML

```
AlarmIdentifier:  AlarmIdentifier
ChildHealthChecks:
   - String
EnableSNI: Boolean
FailureThreshold: Integer
FullyQualifiedDomainName: String
HealthThreshold: Integer
InsufficientDataHealthStatus: String
Inverted: Boolean
IPAddress: String
MeasureLatency: Boolean
Port: Integer
Regions:
   - String
RequestInterval: Integer
ResourcePath: String
SearchString: String
Type: String
```

Properties

`AlarmIdentifier`

Identifies the CloudWatch alarm that you want Route 53 health checkers to use to determine whether this health check is healthy.

Type: Amazon Route 53 HealthCheck AlarmIdentifier (p. 1955)

Required: No

`ChildHealthChecks`

(CALCULATED Health Checks Only) A complex type that contains one `ChildHealthCheck` element for each health check that you want to associate with a `CALCULATED` health check.

Required: No

Type: List of String values

`EnableSNI`

Specifies whether you want Route 53 to send the value of `FullyQualifiedDomainName` to the endpoint in the `client_hello` message during TLS negotiation. This allows the endpoint to respond to `HTTPS` health check requests with the applicable SSL/TLS certificate. For more information, see http://docs.aws.amazon.com/Route53/latest/APIReference/API_HealthCheckConfig.html.

Required: No

Type: Boolean

`FailureThreshold`

The number of consecutive health checks that an endpoint must pass or fail for Route 53 to change the current status of the endpoint from unhealthy to healthy or healthy to unhealthy. For more information, see How Amazon Route 53 Determines Whether an Endpoint Is Healthy in the *Amazon Route 53 Developer Guide*.

Required: No

Type: Integer

`FullyQualifiedDomainName`

If you specified the `IPAddress` property, the value that you want Route 53 to pass in the host header in all health checks except for TCP health checks. If you don't specify an IP address, the domain that Route 53 sends a DNS request to. Route 53 uses the IP address that the DNS returns to check the health of the endpoint.

Required: Conditional

Type: String

`HealthThreshold`

The number of child health checks that are associated with a `CALCULATED` health that Route 53 must consider healthy for the `CALCULATED` health check to be considered healthy.

Required: No

Type: Integer

`InsufficientDataHealthStatus`

When Amazon CloudWatch has insufficient data about the metric to determine the alarm state, the status that you want Route 53 to assign to the health check (`Healthy`, `Unhealthy`, or `LastKnownStatus`).

Required: No

Type: String

`Inverted`

Specifies whether you want Route 53 to invert the status of a health check, for example, to consider a health check unhealthy when it otherwise would be considered healthy.

Required: No

Type: Boolean

`IPAddress`

The IPv4 IP address of the endpoint on which you want Route 53 to perform health checks. If you don't specify an IP address, Route 53 sends a DNS request to resolve the domain name that you specify in the `FullyQualifiedDomainName` property.

Required: No

Type: String

`MeasureLatency`

Specifies whether you want Route 53 to measure the latency between health checkers in multiple AWS regions and your endpoint and display CloudWatch latency graphs on the **Health Checks** page in the Route 53 console.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`Port`

The port on the endpoint on which you want Route 53 to perform health checks.

Required: Conditional. Required when you specify `TCP` for the `Type` property.

Type: Integer

`Regions`

The regions from which you want Amazon Route 53 health checkers to check the specified endpoint.

Duplicates are not allowed. For valid values and more information, see HealthCheckConfig in the *Amazon Route 53 API Reference*.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`RequestInterval`

The number of seconds between the time that Route 53 gets a response from your endpoint and the time that it sends the next health check request. Each Route 53 health checker makes requests at this interval. For valid values, see the RequestInterval element in the *Amazon Route 53 API Reference*.

Required: No

Type: Integer

Update requires: Replacement (p. 121)

`ResourcePath`

The path that you want Route 53 to request when performing health checks. The path can be any value for which your endpoint returns an HTTP status code of `2xx` or `3xx` when the endpoint is healthy, such as `/docs/route53-health-check.html`.

Required: No

Type: String

`SearchString`

If the value of the `Type` property is `HTTP_STR_MATCH` or `HTTPS_STR_MATCH`, the string that you want Route 53 to search for in the response body from the specified resource. If the string appears in the response body, Route 53 considers the resource healthy.

Required: No

Type: String

`Type`

The type of health check that you want to create. This indicates how Route 53 determines whether an endpoint is healthy. You can specify `HTTP`, `HTTPS`, `HTTP_STR_MATCH`, `HTTPS_STR_MATCH`, `TCP`, `CLOUDWATCH_METRIC`, or `CALCULATED`. For information about the different types, see the `Type` element in the *Amazon Route 53 API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Amazon Route 53 HealthCheck HealthCheckTags

The `HealthCheckTags` property describes key-value pairs that are associated with an AWS::Route53::HealthCheck (p. 1953) resource.

Syntax

JSON

```
{
  "Key" : String,
  "Value" : String
}
```

YAML

```
Key: String
Value: String
```

Properties

`Key`

The key name of the tag.

Required: Yes

Type: String

`Value`

The value for the tag.

Required: Yes

Type: String

AWS::Route53::HostedZone

The `AWS::Route53::HostedZone` resource creates a hosted zone, which can contain a collection of record sets for a domain. You cannot create a hosted zone for a top-level domain (TLD). For more information, see POST CreateHostedZone or POST CreateHostedZone (Private) in the *Amazon Route 53 API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Route53::HostedZone",
  "Properties" : {
    "HostedZoneConfig" : HostedZoneConfig (p. 1963),
    "HostedZoneTags" : [ HostedZoneTags (p. 1963), ... ],
    "Name" : String,
    "QueryLoggingConfig" : QueryLoggingConfig (p. 1964),
    "VPCs" : [ HostedZoneVPCs (p. 1964), ... ]
  }
}
```

YAML

```
Type: "AWS::Route53::HostedZone"
Properties:
  HostedZoneConfig:
    HostedZoneConfig (p. 1963)
  HostedZoneTags:
    - HostedZoneTags (p. 1963)
  Name: String
  QueryLoggingConfig:
    QueryLoggingConfig (p. 1964)
  VPCs:
    - HostedZoneVPCs (p. 1964)
```

Properties

`HostedZoneConfig`

A complex type that contains an optional comment about your hosted zone.

Required: No

Type: Route 53 HostedZoneConfig Property (p. 1963)

Update requires: No interruption (p. 120)

`HostedZoneTags`

An arbitrary set of tags (key–value pairs) for this hosted zone.

Required: No

Type: List of Amazon Route 53 HostedZoneTags (p. 1963)

Update requires: No interruption (p. 120)

`Name`

The name of the domain. For resource record types that include a domain name, specify a fully qualified domain name.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`QueryLoggingConfig`

The configuration for DNS query logging.

Required: No

Type: Route 53 QueryLoggingConfig (p. 1964)

Update requires: No interruption (p. 120)

`VPCs`

One or more VPCs that you want to associate with this hosted zone. When you specify this property, AWS CloudFormation creates a private hosted zone.

Required: No

Type: List of Route 53 HostedZoneVPCs (p. 1964)

If this property was specified previously and you're modifying values, updates require no interruption (p. 120). If this property wasn't specified and you add values, updates require replacement (p. 121). Also, if this property was specified and you remove all values, updates require replacement (p. 121).

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "myHostedZone" }
```

`Ref` returns the hosted zone ID, such as `Z23ABC4XYZL05B`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`NameServers`

Returns the set of name servers for the specific hosted zone. For example: `ns1.example.com`.

This attribute is not supported for private hosted zones.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following template snippet creates a private hosted zone for the `example.com` domain.

JSON

```
"DNS": {
  "Type": "AWS::Route53::HostedZone",
  "Properties": {
    "HostedZoneConfig": {
      "Comment": "My hosted zone for example.com"
    },
    "Name": "example.com",
    "VPCs": [{
      "VPCId": "vpc-abcd1234",
      "VPCRegion": "ap-northeast-1"
    },
    {
      "VPCId": "vpc-efgh5678",
      "VPCRegion": "us-west-2"
    }],
    "HostedZoneTags" : [{
      "Key": "SampleKey1",
      "Value": "SampleValue1"
    },
    {
      "Key": "SampleKey2",
      "Value": "SampleValue2"
    }]
  }
}
```

YAML

```
DNS:
  Type: "AWS::Route53::HostedZone"
  Properties:
    HostedZoneConfig:
      Comment: "My hosted zone for example.com"
    Name: "example.com"
    VPCs:
      -
        VPCId: "vpc-abcd1234"
        VPCRegion: "ap-northeast-1"
      -
        VPCId: "vpc-efgh5678"
        VPCRegion: "us-west-2"
    HostedZoneTags:
      -
        Key: "SampleKey1"
        Value: "SampleValue1"
      -
        Key: "SampleKey2"
        Value: "SampleValue2"
```

Route 53 HostedZoneConfig Property

The `HostedZoneConfig` property is part of the AWS::Route53::HostedZone (p. 1960) resource that can contain a comment about the hosted zone.

Syntax

JSON

```
{
  "Comment" : String
}
```

YAML

```
Comment: String
```

Properties

`Comment`

Any comments that you want to include about the hosted zone.

Type: String

Required: No

Amazon Route 53 HostedZoneTags

The `HostedZoneTags` property describes key-value pairs that are associated with an AWS::Route53::HostedZone (p. 1960) resource.

Syntax

JSON

```
{
  "Key" : String,
  "Value" : String
}
```

YAML

```
Key: String
Value: String
```

Properties

`Key`

The key name of the tag.

Required: Yes

Type: String

`Value`

The value for the tag.

Required: Yes

Type: String

Route 53 HostedZoneVPCs

The `HostedZoneVPCs` property is part of the AWS::Route53::HostedZone (p. 1960) resource that specifies the VPCs to associate with the hosted zone.

Syntax

JSON

```
{
  "VPCId" : String,
  "VPCRegion" : String
}
```

YAML

```
VPCId: String
VPCRegion: String
```

Properties

`VPCId`

The ID of the Amazon VPC that you want to associate with the hosted zone.

Required: Yes

Type: String

`VPCRegion`

The region in which the Amazon VPC was created as specified in the `VPCId` property.

Required: Yes

Type: String

Route 53 QueryLoggingConfig

The `QueryLoggingConfig` property is part of the AWS::Route53::HostedZone (p. 1960) resource that specifies a configuration for DNS query logging. After you create a query logging configuration, Amazon Route 53 begins to publish log data to an Amazon CloudWatch Logs log group. For more information, see CreateQueryLoggingConfig in the *Amazon Route 53 API Reference*.

Syntax

JSON

```
{
  "CloudWatchLogsLogGroupArn" : String
```

```
}
```

YAML

```
CloudWatchLogsLogGroupArn: String
```

Properties

`CloudWatchLogsLogGroupArn`

The Amazon Resource Name (ARN) for the log group that you want Amazon Route 53 to send query logs to. This is the format of the ARN:

arn:aws:logs:*region*:*account-id*:log-group:*log_group_name*

Required: Yes

Type: String

AWS::Route53::RecordSet

The `AWS::Route53::RecordSet` type can be used as a standalone resource or as an embedded property in the AWS::Route53::RecordSetGroup (p. 1972) type. Note that some `AWS::Route53::RecordSet` properties are valid only when used within `AWS::Route53::RecordSetGroup`.

For more information about constraints and values for each property, see POST CreateHostedZone for hosted zones and POST ChangeResourceRecordSet for resource record sets.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::Route53::RecordSet",
  "Properties" : {
    "AliasTarget (p. 1966)" : AliasTarget (p. 1970),
    "Comment" : String,
    "Failover" : String,
    "GeoLocation" : GeoLocation,
    "HealthCheckId" : String,
    "HostedZoneId (p. 1967)" : String,
    "HostedZoneName (p. 1967)" : String,
    "Name (p. 1967)" : String,
    "Region (p. 1968)" : String,
    "ResourceRecords (p. 1968)" : [ String ],
    "SetIdentifier (p. 1968)" : String,
    "TTL (p. 1968)" : String,
    "Type (p. 1969)" : String,
    "Weight (p. 1969)" : Integer
  }
}
```

YAML

```
Type: AWS::Route53::RecordSet
```

```
Properties:
  AliasTarget (p. 1966):
    AliasTarget (p. 1970)
  Comment: String
  Failover: String
  GeoLocation:
    GeoLocation
  HealthCheckId: String
  HostedZoneId (p. 1967): String
  HostedZoneName (p. 1967): String
  Name (p. 1967): String
  Region (p. 1968): String
  ResourceRecords (p. 1968):
    - String
  SetIdentifier (p. 1968): String
  TTL (p. 1968): String
  Type (p. 1969): String
  Weight (p. 1969): Integer
```

Properties

`AliasTarget`

Alias resource record sets only: Information about the domain to which you are redirecting traffic.

If you specify this property, do not specify the `TTL` property. The alias uses a TTL value from the alias target record.

For more information about alias resource record sets, see Creating Alias Resource Record Sets in the *Route 53 Developer Guide* and POST ChangeResourceRecordSets in the Route 53 API reference.

Required: Conditional. Required if you are creating an alias resource record set.

Type: AliasTarget (p. 1970)

Update requires: No interruption (p. 120)

`Comment`

Any comments that you want to include about the change batch.

> **Important**
> If the record set is part of a record set group, this property isn't valid. Don't specify this property.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Failover`

Designates the record set as a `PRIMARY` or `SECONDARY` failover record set. When you have more than one resource performing the same function, you can configure Route 53 to check the health of your resources and use only health resources to respond to DNS queries. You cannot create nonfailover resource record sets that have the same `Name` and `Type` property values as failover resource record sets. For more information, see the Failover content in the *Amazon Route 53 API Reference*.

If you specify this property, you must specify the `SetIdentifier` property.

Required: No

Type: String

Update requires: No interruption (p. 120)

`GeoLocation`

Describes how Route 53 responds to DNS queries based on the geographic origin of the query. This property is not compatible with the `Region` property.

Required: No

Type: Route 53 Record Set GeoLocation Property (p. 1971)

Update requires: No interruption (p. 120)

`HealthCheckId`

The health check ID that you want to apply to this record set. Route 53 returns this resource record set in response to a DNS query only while record set is healthy.

Required: No

Type: String

Update requires: No interruption (p. 120)

`HostedZoneId`

The ID of the hosted zone.

Required: Conditional. You must specify either the `HostedZoneName` or `HostedZoneId`, but you cannot specify both. If this record set is part of a record set group, do not specify this property.

Type: String

Update requires: Replacement (p. 121)

`HostedZoneName`

The name of the domain for the hosted zone where you want to add the record set.

When you create a stack using an `AWS::Route53::RecordSet` that specifies `HostedZoneName`, AWS CloudFormation attempts to find a hosted zone whose name matches the `HostedZoneName`. If AWS CloudFormation cannot find a hosted zone with a matching domain name, or if there is more than one hosted zone with the specified domain name, AWS CloudFormation will not create the stack.

If you have multiple hosted zones with the same domain name, you must explicitly specify the hosted zone using `HostedZoneId`.

Required: Conditional. You must specify either the `HostedZoneName` or `HostedZoneId`, but you cannot specify both. If this record set is part of a record set group, do not specify this property.

Type: String

Update requires: Replacement (p. 121)

`Name`

The name of the domain. You must specify a fully qualified domain name that ends with a period as the last label indication. If you omit the final period, Route 53 adds it.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Region`

Latency resource record sets only: The Amazon EC2 region where the resource that is specified in this resource record set resides. The resource typically is an AWS resource, for example, Amazon EC2 instance or an Elastic Load Balancing load balancer, and is referred to by an IP address or a DNS domain name, depending on the record type.

When Route 53 receives a DNS query for a domain name and type for which you have created latency resource record sets, Route 53 selects the latency resource record set that has the lowest latency between the end user and the associated Amazon EC2 region. Route 53 then returns the value that is associated with the selected resource record set.

The following restrictions must be followed:

- You can only specify one resource record per latency resource record set.
- You can only create one latency resource record set for each Amazon EC2 region.
- You are not required to create latency resource record sets for all Amazon EC2 regions. Route 53 will choose the region with the best latency from among the regions for which you create latency resource record sets.
- You cannot create both weighted and latency resource record sets that have the same values for the Name and Type elements.
- This property is not compatible with the `GeoLocation` property.

To see a list of regions by service, see Regions and Endpoints in the *AWS General Reference*.

`ResourceRecords`

List of resource records to add. Each record should be in the format appropriate for the record type specified by the `Type` property. For information about different record types and their record formats, see Values for Basic Resource Record Sets and Appendix: Domain Name Format in the *Route 53 Developer Guide*.

Required: Conditional. If you don't specify the `AliasTarget` property, you must specify this property. If you are creating an alias resource record set, do not specify this property.

Type: List of String values

Update requires: No interruption (p. 120)

`SetIdentifier`

A unique identifier that differentiates among multiple resource record sets that have the same combination of DNS name and type.

Required: Conditional. Required if you are creating a weighted, latency, failover, or geolocation resource record set.

For more information, see the SetIdentifier content in the *Route 53 Developer Guide*.

Type: String

Update requires: No interruption (p. 120)

`TTL`

The resource record cache time to live (TTL), in seconds. If you specify this property, do not specify the `AliasTarget` property. For alias target records, the alias uses a TTL value from the target.

If you specify this property, you must specify the `ResourceRecords` property.

Required: Conditional. If you don't specify the `AliasTarget` property, you must specify this property. If you are creating an alias resource record set, do not specify this property.

Type: String

Update requires: No interruption (p. 120)

`Type`

The type of records to add. For valid values, see the Type content in the *Amazon Route 53 API Reference*.

In AWS CloudFormation, you cannot modify the NS and SOA records for a hosted zone created automatically by Route 53. Specifically, you can't create or delete NS or SOA records for the root domain of your hosted zone, but you can create them for subdomains to delegate. For example, for hosted zone `mydomain.net`, you cannot create an NS record for `mydomain.net` but you can create an NS record for `nnnn.mydomain.net` for delegation.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Weight`

Weighted resource record sets only: Among resource record sets that have the same combination of DNS name and type, a value that determines what portion of traffic for the current resource record set is routed to the associated location.

For more information about weighted resource record sets, see Setting Up Weighted Resource Record Sets in the *Route 53 Developer Guide*.

Required: Conditional. Required if you are creating a weighted resource record set.

Type: Number. Weight expects integer values.

Update requires: No interruption (p. 120)

Return Value

When you specify an `AWS::Route53::RecordSet` type as an argument to the `Ref` function, AWS CloudFormation returns the value of the domain name of the record set.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

Mapping a Route 53 A record to the public IP of an Amazon EC2 instance

JSON

```
"Resources" : {
   "Ec2Instance" : {
      "Type" : "AWS::EC2::Instance",
      "Properties" : {
         "ImageId" : { "Fn::FindInMap" : [
            "RegionMap", { "Ref" : "AWS::Region" }, "AMI"
         ] }
      }
```

```
    },
    "myDNSRecord" : {
       "Type" : "AWS::Route53::RecordSet",
       "Properties" : {
          "HostedZoneName" : { "Ref" : "HostedZoneResource" },
          "Comment" : "DNS name for my instance.",
          "Name" : {
             "Fn::Join" : [ "", [
                {"Ref" : "Ec2Instance"}, ".",
                {"Ref" : "AWS::Region"}, ".",
                {"Ref" : "HostedZone"} ,"."
             ] ]
          },
          "Type" : "A",
          "TTL" : "900",
          "ResourceRecords" : [
             { "Fn::GetAtt" : [ "Ec2Instance", "PublicIp" ] }
          ]
       }
    }
}
```

YAML

```
Resources:
  Ec2Instance:
    Type: AWS::EC2::Instance
    Properties:
      ImageId: !FindInMap [RegionMap, !Ref 'AWS::Region', AMI]
  myDNSRecord:
    Type: AWS::Route53::RecordSet
    Properties:
      HostedZoneName: !Ref 'HostedZoneResource'
      Comment: DNS name for my instance.
      Name: !Join ['', [!Ref 'Ec2Instance', ., !Ref 'AWS::Region', ., !Ref
 'HostedZone', .]]
      Type: A
      TTL: '900'
      ResourceRecords:
      - !GetAtt Ec2Instance.PublicIp
```

Additional Information

For additional `AWS::Route53::RecordSet` snippets, see Route 53 Template Snippets (p. 428) .

Amazon Route 53 AliasTarget Property

`AliasTarget` is a property of the AWS::Route53::RecordSet (p. 1965) resource.

For more information about alias resource record sets, see Creating Alias Resource Record Sets in the *Amazon Route 53 Developer Guide*.

Syntax

JSON

```
{
  "DNSName" : String,
  "EvaluateTargetHealth" : Boolean,
  "HostedZoneId" : String
}
```

YAML

```
DNSName: String
EvaluateTargetHealth: Boolean
HostedZoneId: String
```

Properties

`DNSName`

The DNS name of the load balancer, the domain name of the CloudFront distribution, the website endpoint of the Amazon S3 bucket, or another record set in the same hosted zone that is the target of the alias.

Type: String

Required: Yes

`EvaluateTargetHealth`

Whether Route 53 checks the health of the resource record sets in the alias target when responding to DNS queries. For more information about using this property, see EvaluateTargetHealth in the *Amazon Route 53 API Reference*.

Type: Boolean

Required: No

`HostedZoneId`

The hosted zone ID. For load balancers, use the canonical hosted zone ID of the load balancer. For Amazon S3, use the hosted zone ID for your bucket's website endpoint. For CloudFront, use `Z2FDTNDATAQYW2`. For a list of hosted zone IDs of other services, see the relevant service in the AWS Regions and Endpoints.

Type: String

Required: Yes

Route 53 Record Set GeoLocation Property

The `GeoLocation` property is part of the AWS::Route53::RecordSet (p. 1965) resource that describes how Route 53 responds to DNS queries based on the geographic location of the query. This property is not compatible with the `Region` property.

Syntax

JSON

```
{
  "ContinentCode" : String,
  "CountryCode" : String,
  "SubdivisionCode" : String
}
```

YAML

```
ContinentCode: String
CountryCode: String
SubdivisionCode: String
```

Properties

`ContinentCode`

All DNS queries from the continent that you specified are routed to this resource record set. If you specify this property, omit the `CountryCode` and `SubdivisionCode` properties.

For valid values, see GeoLocation in the *Amazon Route 53 API Reference*.

Type: String

Required: Conditional. You must specify this or the `CountryCode` property.

`CountryCode`

All DNS queries from the country that you specified are routed to this resource record set. If you specify this property, omit the `ContinentCode` property. To specify the default location, use * for this property.

For valid values, see GeoLocation in the *Amazon Route 53 API Reference*.

Type: String

Required: Conditional. You must specify this or the `ContinentCode` property.

`SubdivisionCode`

If you specified `US` for the country code, you can specify a state in the United States. All DNS queries from the state that you specified are routed to this resource record set. If you specify this property, you must specify `US` for the `CountryCode` and omit the `ContinentCode` property.

For valid values, see GeoLocation in the *Amazon Route 53 API Reference*.

Type: String

Required: No

AWS::Route53::RecordSetGroup

The `AWS::Route53::RecordSetGroup` resource creates record sets for a hosted zone. For more information about constraints and values for each property, see POST CreateHostedZone for hosted zones and POST ChangeResourceRecordSet for resource record sets.

Topics

- Syntax (p. 1972)
- Properties (p. 1973)
- Return Value (p. 1974)
- Examples (p. 1974)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::Route53::RecordSetGroup",
   "Properties" : {
      "Comment (p. 1973)" : String,
```

```
      "HostedZoneId (p. 1973)" : String,
      "HostedZoneName (p. 1973)" : String,
      "RecordSets (p. 1973)" : [ RecordSet1, ... ]
   }
}
```

YAML

```
Type: AWS::Route53::RecordSetGroup
Properties:
  Comment (p. 1973): String
  HostedZoneId (p. 1973): String
  HostedZoneName (p. 1973): String
  RecordSets (p. 1973):
    - RecordSet1
```

Properties

`Comment`

Any comments you want to include about the change batch.

Required: No

Type: String

Update requires: No interruption (p. 120)

`HostedZoneId`

The ID of the hosted zone.

Required: Conditional: You must specify either the `HostedZoneName` or `HostedZoneId`, but you cannot specify both.

Type: String

Update requires: Replacement (p. 121)

`HostedZoneName`

The name of the domain for the hosted zone where you want to add the record set.

When you create a stack using an `AWS::Route53::RecordSet` that specifies `HostedZoneName`, AWS CloudFormation attempts to find a hosted zone whose name matches the `HostedZoneName`. If AWS CloudFormation cannot find a hosted zone with a matching domain name, or if there is more than one hosted zone with the specified domain name, AWS CloudFormation will not create the stack.

If you have multiple hosted zones with the same domain name, you must explicitly specify the hosted zone using `HostedZoneId`.

Required: Conditional. You must specify either the `HostedZoneName` or `HostedZoneId`, but you cannot specify both.

Type: String

Update requires: Replacement (p. 121)

`RecordSets`

List of resource record sets to add. The maximum number of records is 1,000.

Required: Yes

Type:: List of AWS::Route53::RecordSet (p. 1965) objects, as shown in the following example:

```
"RecordSets" : [
  {
    "Name" : "mysite.example.com.",
    "Type" : "CNAME",
    "TTL" : "900",
    "SetIdentifier" : "Frontend One",
    "Weight" : "4",
    "ResourceRecords" : ["example-ec2.amazonaws.com"]
  },
  {
    "Name" : "mysite.example.com.",
    "Type" : "CNAME",
    "TTL" : "900",
    "SetIdentifier" : "Frontend Two",
    "Weight" : "6",
    "ResourceRecords" : ["example-ec2-larger.amazonaws.com"]
  }
]
```

Update requires: No interruption (p. 120)

Return Value

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name. For example:

```
{ "Ref": "MyRecordSetGroup" }
```

For the resource with the logical ID "MyRecordSetGroup", `Ref` will return the AWS resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

For AWS::Route53::RecordSetGroup snippets, see Route 53 Template Snippets (p. 428).

AWS::ServiceDiscovery::Instance

The `AWS::ServiceDiscovery::Instance` resource specifies information about an instance that Amazon Route 53 creates. For more information, see Instance in the *Amazon Route 53 API Reference*.

Topics

- Syntax (p. 1974)
- Properties (p. 1975)
- Return Values (p. 1976)
- See Also (p. 1976)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Type" : "AWS::ServiceDiscovery::Instance",
  "Properties" : {
    "InstanceAttributes" : JSON object,
    "InstanceId" : String,
    "ServiceId" : String
  }
}
```

YAML

```
Type: "AWS::ServiceDiscovery::Instance"
Properties:
  InstanceAttributes: JSON object
  InstanceId: String
  ServiceId: String
```

Properties

`InstanceAttributes`

A string map that contains attribute keys and values. Supported attribute keys include the following:

- `AWS_INSTANCE_PORT`: The port on the endpoint that you want Route 53 to perform health checks on. This value is also used for the port value in an SRV record if the service that you specify includes an SRV record. You can also specify a default port that is applied to all instances in the `Service` configuration. For more information, see CreateService in the *Amazon Route 53 API Reference*.
- `AWS_INSTANCE_IPV4`: If the service that you specify contains a resource record set template for an A record, the IPv4 address that you want Route 53 to use for the value of the A record.
- `AWS_INSTANCE_IPV6`: If the service that you specify contains a resource record set template for an AAAA record, the IPv6 address that you want Route 53 to use for the value of the AAAA record.

Required: Yes

Type: JSON object

Update requires: No interruption (p. 120)

`InstanceId`

An identifier that you want to associate with the instance. Note the following:

- You can use this value to update an existing instance.
- To associate a new instance, you must specify a value that is unique among instances that you associate by using the same service.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ServiceId`

The ID of the service that you want to use for settings for the resource record sets and health check that Route 53 will create.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceDiscovery::Instance` resource to the intrinsic `Ref` function, the function returns the value of `Id` for the instance.

For more information about using the `Ref` function, see Ref (p. 2341).

See Also

- Using Autonaming for Service Discovery in the *Amazon Route 53 API Reference*
- RegisterInstance in the *Amazon Route 53 API Reference*
- CreateService in the *Amazon Route 53 API Reference*

AWS::ServiceDiscovery::PrivateDnsNamespace

The `AWS::ServiceDiscovery::PrivateDnsNamespace` resource specifies information about a private namespace for Amazon Route 53. Use a private namespace when you want to route traffic inside an Amazon VPC. For more information, see CreatePrivateDnsNamespace in the *Amazon Route 53 API Reference*.

Topics

- Syntax (p. 1976)
- Properties (p. 1977)
- Return Values (p. 1977)
- See Also (p. 1977)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceDiscovery::PrivateDnsNamespace",
  "Properties" : {
    "Description" : String,
    "Vpc" : String,
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::ServiceDiscovery::PrivateDnsNamespace"
Properties:
  Description: String
  Vpc: String
  Name: String
```

Properties

`Description`

A description for the namespace.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Vpc`

The ID of the Amazon VPC that you want to associate the namespace with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Name`

The name that you want to assign to this namespace. When you create a namespace, Route 53 automatically creates a hosted zone that has the same name as the namespace.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceDiscovery::PrivateDnsNamespace` resource to the intrinsic `Ref` function, the function returns the value of `Id` for the namespace.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Id`

The ID of the private namespace.

`Arn`

The Amazon Resource Name (ARN) of the private namespace.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

See Also

- Using Autonaming for Service Discovery in the *Amazon Route 53 API Reference*
- CreatePrivateDnsNamespace in the *Amazon Route 53 API Reference*

AWS::ServiceDiscovery::PublicDnsNamespace

The `AWS::ServiceDiscovery::PublicDnsNamespace` resource specifies information about a public namespace for Amazon Route 53. Use a public namespace when you want to route internet traffic to your resources. For more information, see CreatePublicDnsNamespace in the *Amazon Route 53 API Reference*.

Topics

- Syntax (p. 1978)
- Properties (p. 1978)
- Return Values (p. 1979)
- See Also (p. 1979)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceDiscovery::PublicDnsNamespace",
  "Properties" : {
    "Description" : String,
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::ServiceDiscovery::PublicDnsNamespace"
Properties:
  Description: String
  Name: String
```

Properties

`Description`

A description for the namespace.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Name`

The name that you want to assign to this namespace. When you create a namespace, Route 53 automatically creates a hosted zone that has the same name as the namespace.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceDiscovery::PublicDnsNamespace` resource to the intrinsic `Ref` function, the function returns the value of `Id` for the namespace.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Id`

The ID of the public namespace.

`Arn`

The Amazon Resource Name (ARN) of the public namespace.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

See Also

- Using Autonaming for Service Discovery in the *Amazon Route 53 API Reference*
- CreatePublicDnsNamespace in the *Amazon Route 53 API Reference*

AWS::ServiceDiscovery::Service

The `AWS::ServiceDiscovery::Service` resource defines a template for up to five records and an optional health check that you want Amazon Route 53 to create when you register an instance. For more information, see CreateService in the *Amazon Route 53 API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceDiscovery::Service",
  "Properties" : {
    "Description" : String,
    "DnsConfig" : DnsConfig (p. 1981),
    "HealthCheckConfig" : HealthCheckConfig (p. 1983),
    "HealthCheckCustomConfig" : HealthCheckCustomConfig (p. 1984),
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::ServiceDiscovery::Service"
Properties:
  Description: String
  DnsConfig:
```

```
    DnsConfig (p. 1981)
  HealthCheckConfig:
    HealthCheckConfig (p. 1983)
 HealthCheckCustomConfig:
    HealthCheckCustomConfig (p. 1984)
  Name: String
```

Properties

`Description`

A description for the service.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DnsConfig`

A complex type that contains information about the resource record sets that you want Route 53 to create when you register an instance.

Required: Yes

Type: DnsConfig (p. 1981)

Update requires: No interruption (p. 120)

`HealthCheckConfig`

A complex type that contains settings for an optional health check. If you specify settings for a health check, Route 53 associates the health check with all the resource record sets that you specify in `DnsConfig`.

If you specify a health check configuration, you can specify either `HealthCheckCustomConfig` or `HealthCheckConfig` but not both.

Required: No

Type: HealthCheckConfig (p. 1983)

Update requires: No interruption (p. 120)

`HealthCheckCustomConfig`

Specifies information about an optional custom health check.

If you specify a health check configuration, you can specify either `HealthCheckCustomConfig` or `HealthCheckConfig` but not both.

Required: No

Type: HealthCheckCustomConfig (p. 1984)

Update requires: No interruption (p. 120)

`Name`

The name that you want to assign to the service.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceDiscovery::Service` resource to the intrinsic `Ref` function, the function returns the value of `Id` for the service.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Id`

The ID of the service.

`Arn`

The Amazon Resource Name (ARN) of the service.

`Name`

The name that you assigned to the service.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

See Also

- Using Autonaming for Service Discovery in the *Amazon Route 53 API Reference*
- CreateService in the *Amazon Route 53 API Reference*

Amazon Route 53 ServiceDiscovery DnsConfig

The `DnsConfig` property type specifies settings for the records that you want Amazon Route 53 to create when you register an instance

`DnsConfig` is a property of the AWS::ServiceDiscovery::Service (p. 1979) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "DnsRecords" : [ DnsRecord (p. 1982), ... ],
  "NamespaceId" : String
}
```

YAML

```
DnsRecords:
  - DnsRecord (p. 1982)
NamespaceId: String
```

Properties

`DnsRecords`

Contains one `DnsRecord` element for each DNS record that you want Route 53 to create when you register an instance.

Required: Yes

Type: List of DnsRecord (p. 1982)

Update requires: No interruption (p. 120)

`NamespaceId`

The ID of the namespace that you want to use for DNS configuration.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

See Also

- Using Autonaming for Service Discovery in the *Amazon Route 53 API Reference*
- CreateService in the *Amazon Route 53 API Reference*

Amazon Route 53 ServiceDiscovery DnsRecord

The `DnsRecord` property type specifies settings for one DNS record that you want Amazon Route 53 to create when you register an instance.

The `DnsRecords` property of the DnsConfig (p. 1981) property type contains a list of `DnsRecord` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : String,
  "TTL" : String
}
```

YAML

```
Type: String
TTL: String
```

Properties

`Type`

The DNS type of the record that you want Route 53 to create. Supported record types include `A`, `AAAA`, and `SRV`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`TTL`

The amount of time, in seconds, that you want DNS resolvers to cache the settings for this record.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

See Also

- Using Autonaming for Service Discovery in the *Amazon Route 53 API Reference*
- CreateService in the *Amazon Route 53 API Reference*

Amazon Route 53 ServiceDiscovery HealthCheckConfig

The `HealthCheckConfig` property type specifies settings for an optional Amazon Route 53 health check. If you specify settings for a health check, Route 53 associates the health check with all the resource record sets that you specify in `DnsConfig`.

`HealthCheckConfig` is a property of the AWS::ServiceDiscovery::Service (p. 1979) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : String,
  "ResourcePath" : String,
  "FailureThreshold" : Double
}
```

YAML

```
Type: String
ResourcePath: String
FailureThreshold: Double
```

Properties

`Type`

The type of health check that you want to create, which indicates how Route 53 determines whether an endpoint is healthy. Valid types include `HTTP`, `HTTPS`, and `TCP`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ResourcePath`

The path that you want Route 53 to request when performing health checks. The path can be any value for which your endpoint will return an HTTP status code of 2xx or 3xx when the endpoint is healthy, such as the file `/docs/route53-health-check.html`. Route 53 automatically adds the DNS name for the service and a leading forward slash (/) character.

Required: No

Type: String

Update requires: No interruption (p. 120)

`FailureThreshold`

The number of consecutive health checks that an endpoint must pass or fail for Route 53 to change the current status of the endpoint from unhealthy to healthy or vice versa. For more information, see How Route 53 Determines Whether an Endpoint Is Healthy in the *Amazon Route 53 Developer Guide*

Required: No

Type: Double

Update requires: No interruption (p. 120)

See Also

- Using Autonaming for Service Discovery in the *Amazon Route 53 API Reference*
- CreateService in the *Amazon Route 53 API Reference*

Route 53 ServiceDiscovery Service HealthCheckCustomConfig

The `HealthCheckCustomConfig` property type specifies information about an optional custom health check.

`HealthCheckCustomConfig` is a property of the AWS::ServiceDiscovery::Service (p. 1979) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "FailureThreshold" : Double
}
```

YAML

```
FailureThreshold: Double
```

Properties

`FailureThreshold`

The number of 30-second intervals that you want service discovery to wait after receiving an `UpdateInstanceCustomHealthStatus` request before it changes the health status of a service instance. For example, suppose you specify a value of 2 for `FailureTheshold` , and then your

application sends an `UpdateInstanceCustomHealthStatus` request. Service discovery waits for approximately 60 seconds (2 x 30) before changing the status of the service instance based on that request.

Sending a second or subsequent `UpdateInstanceCustomHealthStatus` request with the same value before `FailureThreshold` x 30 seconds has passed doesn't accelerate the change. Service discovery still waits `FailureThreshold` x 30 seconds after the first request to make the change.

Minimum value of 1. Maximum value of 10.

Required: No

Type: Double

Update requires: No interruption (p. 120)

See Also

- HealthCheckCustomConfig in the *Amazon Route 53 API Reference*

Amazon Simple Storage Service Resource Types Reference

This section contains reference information for all Amazon Simple Storage Service resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::S3::data-type-name
```

Topics

- AWS::S3::Bucket (p. 1985)
- AWS::S3::BucketPolicy (p. 2037)

AWS::S3::Bucket

The `AWS::S3::Bucket` resource creates an Amazon Simple Storage Service (Amazon S3) bucket in the same AWS Region where you create the AWS CloudFormation stack.

To control how AWS CloudFormation handles the bucket when the stack is deleted, you can set a deletion policy for your bucket. For Amazon S3 buckets, you can choose to *retain* the bucket or to *delete* the bucket. For more information, see DeletionPolicy Attribute (p. 2273).

> **Important**
> You can only delete empty buckets. Deletion fails for buckets that have contents.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::S3::Bucket",
```

```
  "Properties" : {
    "AccessControl" : String,
    "AccelerateConfiguration" : AccelerateConfiguration (p. 2002),
    "AnalyticsConfigurations" : [ AnalyticsConfiguration (p. 2004), ... ],
    "BucketEncryption" : BucketEncryption (p. 2005),
    "BucketName" : String,
    "CorsConfiguration" : CorsConfiguration,
    "InventoryConfigurations" : [ InventoryConfiguration (p. 2011), ... ],
    "LifecycleConfiguration" : LifecycleConfiguration,
    "LoggingConfiguration" : LoggingConfiguration,
    "MetricsConfigurations" : [ MetricsConfiguration (p. 2016), ... ]
    "NotificationConfiguration" : NotificationConfiguration,
    "ReplicationConfiguration" : ReplicationConfiguration,
    "Tags" : [ Resource Tag, ... ],
    "VersioningConfiguration" : VersioningConfiguration,
    "WebsiteConfiguration" : WebsiteConfiguration
  }
}
```

YAML

```
Type: AWS::S3::Bucket
Properties:
  AccessControl: String
  AccelerateConfiguration:
    AccelerateConfiguration (p. 2002)
  AnalyticsConfigurations:
    - AnalyticsConfiguration (p. 2004)
  BucketEncryption:
    BucketEncryption (p. 2005)
  BucketName: String
  CorsConfiguration:
    CorsConfiguration
  InventoryConfigurations:
    - InventoryConfiguration (p. 2011)
  LifecycleConfiguration:
    LifecycleConfiguration
  LoggingConfiguration:
    LoggingConfiguration
  MetricsConfigurations:
    - MetricsConfiguration (p. 2016)
  NotificationConfiguration:
    NotificationConfiguration
  ReplicationConfiguration:
    ReplicationConfiguration
  Tags:
    - Resource Tag
  VersioningConfiguration:
    VersioningConfiguration
  WebsiteConfiguration:
    WebsiteConfiguration
```

Properties

`AccessControl`

A canned access control list (ACL) that grants predefined permissions to the bucket. For more information about canned ACLs, see Canned ACLs in the Amazon S3 documentation in the *Amazon Simple Storage Service Developer Guide*.

Required: No

Type: String

Valid values: `AuthenticatedRead` | `AwsExecRead` | `BucketOwnerRead` | `BucketOwnerFullControl` | `LogDeliveryWrite` | `Private` | `PublicRead` | `PublicReadWrite`

Update requires: No interruption (p. 120)

`AccelerateConfiguration`

Configuration for the transfer acceleration state. For more information, see Amazon S3 Transfer Acceleration in the *Amazon Simple Storage Service Developer Guide*.

Required: No

Type: AccelerateConfiguration (p. 2002)

Update requires: No interruption (p. 120)

`AnalyticsConfigurations`

The configuration and any analyses for the analytics filter of an Amazon S3 bucket. Duplicates not allowed.

Required: No

Type: List of AnalyticsConfiguration (p. 2004)

Update requires: No interruption (p. 120)

`BucketEncryption`

Specifies default encryption for a bucket using server-side encryption with either Amazon S3-managed keys (SSE-S3) or AWS KMS-managed keys (SSE-KMS).

Required: No

Type: Amazon S3 Bucket BucketEncryption (p. 2005)

Update requires: No interruption (p. 120)

`BucketName`

A name for the bucket. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the bucket name. For more information, see Name Type (p. 2256). The bucket name must contain only lowercase letters, numbers, periods (.), and dashes (-).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`CorsConfiguration`

Rules that define cross-origin resource sharing of objects in this bucket. For more information, see Enabling Cross-Origin Resource Sharing in the *Amazon Simple Storage Service Developer Guide*.

Required: No

Type: Amazon S3 Bucket CorsConfiguration (p. 2006)

Update requires: No interruption (p. 120)

`InventoryConfigurations`

The inventory configuration for an Amazon S3 bucket. Duplicates not allowed.

Required: No

Type: List of InventoryConfiguration (p. 2011)

Update requires: No interruption (p. 120)

`LifecycleConfiguration`

Rules that define how Amazon S3 manages objects during their lifetime. For more information, see Object Lifecycle Management in the *Amazon Simple Storage Service Developer Guide*.

Required: No

Type: Amazon S3 Bucket LifecycleConfiguration (p. 2014)

Update requires: No interruption (p. 120)

`LoggingConfiguration`

Settings that define where logs are stored.

Required: No

Type: Amazon S3 Bucket LoggingConfiguration (p. 2015)

Update requires: No interruption (p. 120)

`MetricsConfigurations`

Settings that define a metrics configuration for the CloudWatch request metrics from the bucket. For a list of request metrics, see Amazon S3 CloudWatch Request Metrics in the *Amazon Simple Storage Service Developer Guide*.

Required: No

Type: List of MetricsConfiguration (p. 2016)

Update requires: No interruption (p. 120)

Duplicates not allowed.

`NotificationConfiguration`

Configuration that defines how Amazon S3 handles bucket notifications.

Required: No

Type: Amazon S3 Bucket NotificationConfiguration (p. 2017)

Update requires: No interruption (p. 120)

`ReplicationConfiguration`

Configuration for replicating objects in an S3 bucket. To enable replication, you must also enable versioning by using the `VersioningConfiguration` property.

Amazon S3 can store replicated objects in only one destination (S3 bucket). The destination bucket must already exist and be in a different AWS Region than your source bucket.

Required: No

Type: Amazon S3 Bucket ReplicationConfiguration (p. 2022)

Update requires: No interruption (p. 120)

`Tags`

An arbitrary set of tags (key-value pairs) for this S3 bucket.

> **Important**
> We recommend limiting the number of tags to seven. Applying more than seven tags prevents the AWS CLI and the AWS CloudFormation console and API actions from listing the tags for the S3 bucket.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

`VersioningConfiguration`

Enables multiple variants of all objects in this bucket. You might enable versioning to prevent objects from being deleted or overwritten by mistake or to archive objects so that you can retrieve previous versions of them.

Required: No

Type: Amazon S3 Bucket VersioningConfiguration (p. 2035)

Update requires: No interruption (p. 120)

`WebsiteConfiguration`

Information used to configure the bucket as a static website. For more information, see Hosting Websites on Amazon S3.

Required: No

Type: Website Configuration Type (p. 2036)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

Example: `mystack-mybucket-kdwwxmddtr2g`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

Returns the Amazon Resource Name (ARN) of the specified bucket.

Example: `arn:aws:s3:::mybucket`

`DomainName`

Returns the IPv4 DNS name of the specified bucket.

Example: `mystack-mybucket-kdwwxmddtr2g.s3.amazonaws.com`

`DualStackDomainName`

Returns the IPv6 DNS name of the specified bucket.

Example: `mystack-mybucket-kdwwxmddtr2g.s3.dualstack.us-east-2.amazonaws.com`

For more information about dual-stack endpoints, see Using Amazon S3 Dual-Stack Endpoints.

`WebsiteURL`

Returns the Amazon S3 website endpoint for the specified bucket.

Example (IPv4): `http://mystack-mybucket-kdwwxmddtr2g.s3-website-us-east-2.amazonaws.com/`

Example (IPv6): `http://mystack-mybucket-kdwwxmddtr2g.s3.dualstack.us-east-2.amazonaws.com/`

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Associate a Replication Configuration IAM Role with an S3 Bucket

The following example creates an S3 bucket and grants it permission to write to a replication bucket by using an AWS Identity and Access Management (IAM) role. To avoid a circular dependency, the role's policy is declared as a separate resource. The bucket depends on the `WorkItemBucketBackupRole` role. If the policy is included in the role, the role also depends on the bucket.

    Roles: [!Ref 'WorkItemBucketBackupRole']
```

Configure a Static Website with a Routing Rule

In this example, `AWS::S3::Bucket's Fn::GetAtt` values are used to provide outputs. If an HTTP 404 error occurs, the routing rule redirects requests to an EC2 instance and inserts the object key prefix `report-404/` in the redirect. For example, if you request a page called `ExamplePage.html` and it results in an HTTP 404 error, the request is routed to a page called `report-404/ExamplePage.html` on the specified instance. For all other HTTP error codes, `error.html` is returned.

This example also specifies a metrics configuration called `EntireBucket` that enables CloudWatch request metrics at the bucket level.

JSON

```
"Resources" : {
   "S3Bucket" : {
      "Type" : "AWS::S3::Bucket",
      "Properties" : {

Enable Cross-Origin Resource Sharing

The following example template shows an S3 bucket with two cross-origin resource sharing rules.

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
        "S3Bucket": {
            "Type": "AWS::S3::Bucket",
            "Properties": {
                "AccessControl": "PublicReadWrite",
                "CorsConfiguration": {
                    "CorsRules": [
                        {
                            "AllowedHeaders": [
                                "*"
                            ],
                            "AllowedMethods": [
                                "GET"
                            ],
                            "AllowedOrigins": [
                                "*"
                            ],
                            "ExposedHeaders": [
                                "Date"
                            ],
                            "Id": "myCORSRuleId1",
                            "MaxAge": "3600"
                        },

    Description: Name of the sample Amazon S3 bucket with CORS enabled.
```

Manage the Lifecycle for Amazon S3 Objects

The following example template shows an S3 bucket with a lifecycle configuration rule. The rule applies to all objects with the `glacier` key prefix. The objects are transitioned to Amazon Glacier after one day, and deleted after one year.

JSON

```
{
```

```
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "S3Bucket": {
            "Type": "AWS::S3::Bucket",
            "Properties": {
                "AccessControl": "PublicReadWrite",
                "LifecycleConfiguration": {
                    "Rules": [
                        {
                            "Id": "GlacierRule",
                            "Prefix": "glacier",
                            "Status": "Enabled",
                            "ExpirationInDays": "365",
                            "Transitions": [
                                {
                                  "TransitionInDays": "1",
                                  "StorageClass": "Glacier"
                                }
                            ]
                        }
                    ]
                }
            }
        }
    },
    "Outputs": {
        "BucketName": {
            "Value": {
                "Ref": "S3Bucket"
            },
            "Description": "Name of the sample Amazon S3 bucket with a lifecycle
 configuration."
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  S3Bucket:
    Type: AWS::S3::Bucket
    Properties:
      AccessControl: PublicReadWrite
      LifecycleConfiguration:
        Rules:
        - Id: GlacierRule
          Prefix: glacier
          Status: Enabled
          ExpirationInDays: '365'
          Transitions:
            - TransitionInDays: '1'
              StorageClass: Glacier
Outputs:

    Value: !Ref 'S3Bucket'
    Description: Name of the sample Amazon S3 bucket with a lifecycle configuration.
```

Log Access Requests for a Specific S3 Bucket

The following example template creates two S3 buckets. The `LoggingBucket` bucket store the logs from the `S3Bucket` bucket. To receive logs from the `S3Bucket` bucket, the logging bucket requires log delivery write permissions.

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "S3Bucket": {
            "Type": "AWS::S3::Bucket",
            "Properties": {
                "AccessControl": "PublicRead",
                "LoggingConfiguration": {
                    "DestinationBucketName": {"Ref" : "LoggingBucket"},
                    "LogFilePrefix": "testing-logs"
                }
            }
        },
        "LoggingBucket": {
            "Type": "AWS::S3::Bucket",
            "Properties": {
                "AccessControl": "LogDeliveryWrite"
            }
        }
    },
    "Outputs": {
        "BucketName": {
            "Value": {
                "Ref": "S3Bucket"
            },
            "Description": "Name of the sample Amazon S3 bucket with a logging
 configuration."
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  S3Bucket:
    Type: AWS::S3::Bucket
    Properties:
      AccessControl: PublicRead
      LoggingConfiguration:
        DestinationBucketName: !Ref 'LoggingBucket'
        LogFilePrefix: testing-logs
  LoggingBucket:
    Type: AWS::S3::Bucket
    Properties:
      AccessControl: LogDeliveryWrite
Outputs:
  BucketName:
    Value: !Ref 'S3Bucket'
    Description: Name of the sample Amazon S3 bucket with a logging configuration.
```

Receive S3 Bucket Notifications to an SNS Topic

The following example template shows an S3 bucket with a notification configuration that sends an event to the specified SNS topic when Amazon S3 has lost all replicas of an object.

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
```

```
    "Resources": {
        "S3Bucket": {
            "Type": "AWS::S3::Bucket",
            "Properties": {
                "AccessControl": "PublicReadWrite",
                "NotificationConfiguration": {
                    "TopicConfigurations": [
                        {
                            "Topic": "arn:aws:sns:us-east-1:123456789012:TestTopic",
                            "Event": "s3:ReducedRedundancyLostObject"
                        }
                    ]
                }
            }
        }
    },
    "Outputs": {
        "BucketName": {
            "Value": {
                "Ref": "S3Bucket"
            },
            "Description": "Name of the sample Amazon S3 bucket with a notification
 configuration."
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  S3Bucket:
    Type: AWS::S3::Bucket
    Properties:
      AccessControl: PublicReadWrite
      NotificationConfiguration:
        TopicConfigurations:
        - Topic: arn:aws:sns:us-east-1:123456789012:TestTopic
          Event: s3:ReducedRedundancyLostObject
Outputs:
  BucketName:
    Value: !Ref 'S3Bucket'
    Description: Name of the sample Amazon S3 bucket with a notification configuration.
```

Replicate Objects and Store Them in Another S3 Bucket

The following example includes two replication rules. Amazon S3 replicates objects with the `MyPrefix` or `MyOtherPrefix` prefixes and stores them in the `my-replication-bucket` bucket, which must be in a different AWS Region than the `S3Bucket` bucket.

JSON

```
"S3Bucket": {
  "Type": "AWS::S3::Bucket",
  "Properties": {
    "VersioningConfiguration":{
      "Status":"Enabled"
    },
    "ReplicationConfiguration": {
      "Role": "arn:aws:iam::123456789012:role/replication_role",
      "Rules": [
        {
          "Id": "MyRule1",
```

```
          "Status": "Enabled",
          "Prefix": "MyPrefix",
          "Destination": {
            "Bucket": "arn:aws:s3:::my-replication-bucket",
            "StorageClass": "STANDARD"
          }
        },
        {
          "Status": "Enabled",
          "Prefix": "MyOtherPrefix",
          "Destination": {
            "Bucket": "arn:aws:s3:::my-replication-bucket"
          }
        }
      ]
    }
  }
}
```

YAML

```
S3Bucket:
  Type: AWS::S3::Bucket
  Properties:
    VersioningConfiguration:
      Status: Enabled
    ReplicationConfiguration:
      Role: arn:aws:iam::123456789012:role/replication_role
      Rules:
      - Id: MyRule1
        Status: Enabled
        Prefix: MyPrefix
        Destination:
          Bucket: arn:aws:s3:::my-replication-bucket
          StorageClass: STANDARD
      - Status: Enabled
        Prefix: MyOtherPrefix
        Destination:
          Bucket: arn:aws:s3:::my-replication-bucket
```

Specify Analytics and Inventory Configurations for an Amazon S3 Bucket

The following example specifies analytics and inventory results to be generated for an S3 bucket, including the format of the results and the bucket to which they are published. The inventory list is enabled to generate weekly, and only includes the current version of each object.

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "S3 Bucket with Inventory and Analytics Configurations",
    "Resources": {
        "Helper": {
            "Type": "AWS::S3::Bucket"
        },
        "S3Bucket": {
            "Type": "AWS::S3::Bucket",
            "Properties": {
                "AnalyticsConfigurations": [
                    {
                        "Id": "AnalyticsConfigurationId",
                        "StorageClassAnalysis": {
                            "DataExport": {
```

```
                                "Destination": {
                                    "BucketArn": {
                                        "Fn::GetAtt": [
                                            "Helper",
                                            "Arn"
                                        ]
                                    },
                                    "Format": "CSV",
                                    "Prefix": "AnalyticsDestinationPrefix"
                                },
                                "OutputSchemaVersion": "V_1"
                            }
                        },
                        "Prefix": "AnalyticsConfigurationPrefix",
                        "TagFilters": [
                            {
                                "Key": "AnalyticsTagKey",
                                "Value": "AnalyticsTagValue"
                            }
                        ]
                    }
                ],
                "InventoryConfigurations": [
                    {
                        "Id": "InventoryConfigurationId",
                        "Destination": {
                            "BucketArn": {
                                "Fn::GetAtt": [
                                    "Helper",
                                    "Arn"
                                ]
                            },
                            "Format": "CSV",
                            "Prefix": "InventoryDestinationPrefix"
                        },
                        "Enabled": "true",
                        "IncludedObjectVersions": "Current",
                        "Prefix": "InventoryConfigurationPrefix",
                        "ScheduleFrequency": "Weekly"
                    }
                ]
            }
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Description: S3 Bucket with Inventory and Analytics Configurations
Resources:
  Helper:
    Type: AWS::S3::Bucket
  S3Bucket:
    Type: AWS::S3::Bucket
    Properties:
      AnalyticsConfigurations:
        - Id: AnalyticsConfigurationId
          StorageClassAnalysis:
            DataExport:
              Destination:
                BucketArn: !GetAtt
                  - Helper
                  - Arn
```

```
                Format: CSV
                Prefix: AnalyticsDestinationPrefix
              OutputSchemaVersion: V_1
          Prefix: AnalyticsConfigurationPrefix
          TagFilters:
            - Key: AnalyticsTagKey
              Value: AnalyticsTagValue
      InventoryConfigurations:

          Enabled: 'true'
          IncludedObjectVersions: Current
          Prefix: InventoryConfigurationPrefix
          ScheduleFrequency: Weekly
```

Create a Bucket with Default Encryption Enabled

The following example creates a bucket with server-side bucket encryption configured. This example uses S3-managed keys. You can use KMS-managed keys instead by modifying the Amazon S3 Bucket ServerSideEncryptionByDefault (p. 2030) property.

JSON

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Description": "S3 bucket with default encryption",
  "Resources": {
    "EncryptedS3Bucket": {
      "Type": "AWS::S3::Bucket",
      "Properties": {
        "BucketName": {
          "Fn::Sub": "encryptedbucket-${AWS::Region}-${AWS::AccountId}"
        },
        "BucketEncryption": {
          "ServerSideEncryptionConfiguration": [{
            "ServerSideEncryptionByDefault": {
              "SSEAlgorithm": "AES256"
            }
          }]
        }
      },
      "DeletionPolicy": "Delete"
    }
  }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Description: S3 bucket with default encryption
Resources:
  EncryptedS3Bucket:
    Type: AWS::S3::Bucket
    Properties:
      BucketName: !Sub 'encryptedbucket-${AWS::Region}-${AWS::AccountId}'
      BucketEncryption:
        ServerSideEncryptionConfiguration:
          - ServerSideEncryptionByDefault:
```

```
            SSEAlgorithm: AES256
    DeletionPolicy: Delete
```

More Info

- For more examples, see Amazon S3 Template Snippets (p. 432).
- DeletionPolicy Attribute (p. 2273)
- Access Control List (ACL) Overview in the *Amazon Simple Storage Service Developer Guide*
- Hosting a Static Website on Amazon S3 in the *Amazon Simple Storage Service Developer Guide*

Amazon S3 Bucket AbortIncompleteMultipartUpload

The `AbortIncompleteMultipartUpload` property type creates a lifecycle rule that aborts incomplete multipart uploads to an Amazon S3 bucket. When Amazon S3 aborts a multipart upload, it deletes all parts associated with the multipart upload. For more information, see Aborting Incomplete Multipart Uploads Using a Bucket Lifecycle Policy in the *Amazon Simple Storage Service Developer Guide*.

`AbortIncompleteMultipartUpload` is a property of the Amazon S3 Bucket Rule (p. 2026) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "DaysAfterInitiation" : Integer
}
```

YAML

```
DaysAfterInitiation: Integer
```

Properties

`DaysAfterInitiation`

The number of days after the upload is initiated before aborting the upload.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

Amazon S3 Bucket AccelerateConfiguration

The `AccelerateConfiguration` property type configures the transfer acceleration state for an Amazon S3 bucket. For more information, see Amazon S3 Transfer Acceleration in the *Amazon Simple Storage Service Developer Guide*.

`AccelerateConfiguration` is a property of the AWS::S3::Bucket (p. 1985) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "AccelerationStatus" : String
}
```

YAML

```
AccelerationStatus: String
```

Properties

`AccelerationStatus`

Sets the transfer acceleration state of the bucket.

Required: Yes

Type: String

Valid values: `Enabled`, `Suspended`

Update requires: No interruption (p. 120)

Example

The following example sets the transfer acceleration state of a bucket based on the `AccelerateStatus` parameter.

JSON

```
{
 "AWSTemplateFormatVersion":"2010-09-09",
 "Parameters" : {
  "AccelerateStatus" : {
   "Type" : "String"
  }
 },
 "Resources":{
  "MyBucket":{
   "Type":"AWS::S3::Bucket",
   "Properties" : {
    "AccelerateConfiguration" : {
     "AccelerationStatus" : {"Ref" : "AccelerateStatus"}
    }
   }
  }
 }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Parameters:
  AccelerateStatus:
    Type: String
Resources:
  MyBucket:
    Type: AWS::S3::Bucket
```

```
    Properties:
      AccelerateConfiguration:
        AccelerationStatus: !Ref AccelerateStatus
```

Amazon S3 Bucket AccessControlTranslation

The `AccessControlTranslation` property type specifies replica ownership of the AWS account that owns the destination bucket.

`AccessControlTranslation` is a property of the Amazon S3 Bucket ReplicationDestination (p. 2022) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Owner" : String
}
```

YAML

```
Owner: String
```

Properties

`Owner`

Specifies the replica ownership. For default and valid values, see PUT bucket replication in the *Amazon Simple Storage Service API Reference*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon S3 Bucket AnalyticsConfiguration

The `AnalyticsConfiguration` property type specifies the configuration and any analyses for the analytics filter of an Amazon S3 bucket.

For more information, see GET Bucket analytics in the *Amazon Simple Storage Service API Reference*

`AnalyticsConfigurations` is a property of the AWS::S3::Bucket (p. 1985) resource type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Id" : String,
  "Prefix" : String,
  "StorageClassAnalysis" : StorageClassAnalysis (p. 2032),
  "TagFilters" : [ TagFilter (p. 2033), ... ]
```

```
}
```

YAML

```
Id: String
Prefix: String
StorageClassAnalysis: StorageClassAnalysis
TagFilters:
  - TagFilter (p. 2033)
```

Properties

`Id`

The ID that identifies the analytics configuration.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Prefix`

The prefix that an object must have to be included in the analytics results.

Required: No

Type: String

Update requires: No interruption (p. 120)

`StorageClassAnalysis`

Contains data related to access patterns to be collected and made available to analyze the tradeoffs between different storage classes.

Required: Yes

Type: Amazon S3 Bucket StorageClassAnalysis (p. 2032)

Update requires: No interruption (p. 120)

`TagFilters`

The tags to use when evaluating an analytics filter.

The analytics only includes objects that meet the filter's criteria. If no filter is speciified, all of the contents of the bucket are included in the analysis.

Required: No

Type: List of Amazon S3 Bucket TagFilter (p. 2033)

Update requires: No interruption (p. 120)

Amazon S3 Bucket BucketEncryption

The `BucketEncryption` property is part of the AWS::S3::Bucket (p. 1985) resource that specifies default encryption for a bucket using server-side encryption with Amazon S3-managed keys SSE-S3 or AWS KMS-managed Keys (SSE-KMS) bucket. For information about the Amazon S3 default encryption feature, see Amazon S3 Default Bucket Encryption in the *Amazon Simple Storage Service Developer Guide*.

Syntax

JSON

```
{
  "ServerSideEncryptionConfiguration" : [ ServerSideEncryptionRule (p. 2031), ... ]
}
```

YAML

```
ServerSideEncryptionConfiguration:
  - ServerSideEncryptionRule (p. 2031)
```

Properties

`ServerSideEncryptionConfiguration`

Specifies the server-side encryption by default configuration.

Required: Yes

Type: List of Amazon S3 Bucket ServerSideEncryptionRule (p. 2031)

Update requires: No interruption (p. 120)

Amazon S3 Bucket CorsConfiguration

Describes the cross-origin access configuration for objects in an AWS::S3::Bucket (p. 1985) resource.

Syntax

JSON

```
{
  "CorsRules" : [ CorsRules, ... ]
}
```

YAML

```
CorsRules:
  - CorsRules
```

Properties

`CorsRules`

A set of origins and methods that you allow.

Required: Yes

Type: Amazon S3 Bucket CorsRule (p. 2006)

Amazon S3 Bucket CorsRule

Describes cross-origin access rules for the Amazon S3 Bucket CorsConfiguration (p. 2006) property.

Syntax

JSON

```
{
  "AllowedHeaders" : [ String, ... ],
  "AllowedMethods" : [ String, ... ],
  "AllowedOrigins" : [ String, ... ],
  "ExposedHeaders" : [ String, ... ],
  "Id" : String,
  "MaxAge" : Integer
}
```

YAML

```
AllowedHeaders:
  - String
AllowedMethods:
  - String
AllowedOrigins:
  - String
ExposedHeaders:
  - String
Id: String
MaxAge: Integer
```

Properties

`AllowedHeaders`

Headers that are specified in the `Access-Control-Request-Headers` header. These headers are allowed in a preflight OPTIONS request. In response to any preflight OPTIONS request, Amazon S3 returns any requested headers that are allowed.

Required: No

Type: List of String values

`AllowedMethods`

An HTTP method that you allow the origin to execute. The valid values are `GET`, `PUT`, `HEAD`, `POST`, and `DELETE`.

Required: Yes

Type: List of String values

`AllowedOrigins`

An origin that you allow to send cross-domain requests.

Required: Yes

Type: List of String values

`ExposedHeaders`

One or more headers in the response that are accessible to client applications (for example, from a JavaScript XMLHttpRequest object).

Required: No

Type: List of String values

`Id`

A unique identifier for this rule. The value cannot be more than 255 characters.

Required: No

Type: String

`MaxAge`

The time in seconds that your browser is to cache the preflight response for the specified resource.

Required: No

Type: Integer

Amazon S3 Bucket DataExport

The `DataExport` property type specifies how data related to the storage class analysis should be exported for an Amazon S3 bucket.

`DataExport` is a property of the Amazon S3 Bucket StorageClassAnalysis (p. 2032) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Destination" : Destination (p. 2009),
  "OutputSchemaVersion" : String
}
```

YAML

```
Destination: Destination
OutputSchemaVersion: String
```

Properties

`Destination`

Information about where to publish the analytics results.

Required: Yes

Type: Destination (p. 2009)

Update requires: No interruption (p. 120)

`OutputSchemaVersion`

The version of the output schema to use when exporting data. Must be V_1.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon S3 Bucket Destination

The `Destination` property type specifies information about where to publish analysis or configuration results for an Amazon S3 bucket.

`Destination` is a property of the DataExport (p. 2008) and InventoryConfiguration (p. 2011) property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "BucketAccountId" : String,
  "BucketArn" : String,
  "Format" : String,
  "Prefix" : String
}
```

YAML

```
BucketAccountId: String
BucketArn: String
Format: String
Prefix: String
```

Properties

`BucketAccountId`

The ID of the account that owns the destination bucket where the analytics is published.

Although optional, we recommend that the value be set to prevent problems if the destination bucket ownership changes.

Required: No

Type: String

Update requires: No interruption (p. 120)

`BucketArn`

The Amazon Resource Name (ARN) of the bucket where analytics results are published. This destination bucket must be in the same region as the bucket used for the analytics or inventory configuration.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Format`

Specifies the output format of the analytics or inventory results. Currently, Amazon S3 supports the comma-separated value (CSV) format.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Prefix`

The prefix that is prepended to all analytics results.

Required: No

Type: String

Update requires: No interruption (p. 120)

Amazon S3 Bucket EncryptionConfiguration

The `EncryptionConfiguration` property type specifies encryption-related information for an Amazon S3 bucket that is a destination for replicated objects.

`EncryptionConfiguration` is a property of the Amazon S3 Bucket ReplicationDestination (p. 2022) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ReplicaKmsKeyID" : String
}
```

YAML

```
ReplicaKmsKeyID: String
```

Properties

`ReplicaKmsKeyID`

Specifies the AWS KMS Key ID (Key ARN or Alias ARN) for the destination bucket. Amazon S3 uses this key to encrypt replicas.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon S3 Bucket FilterRule

`Rules` is a property of the Amazon S3 Bucket S3KeyFilter (p. 2029) property that describes the Amazon Simple Storage Service (Amazon S3) object key name to filter on and whether to filter on the suffix or prefix of the key name.

Syntax

JSON

```
{
  "Name" : String,
```

```
  "Value" : String
}
```

YAML

```
Name: String
Value: String
```

Properties

`Name`

Whether the filter matches the prefix or suffix of object key names. For valid values, see the `Name` request element of the PUT Bucket notification action in the *Amazon Simple Storage Service API Reference*.

Required: Yes

Type: String

`Value`

The value that the filter searches for in object key names.

Required: Yes

Type: String

Amazon S3 Bucket InventoryConfiguration

The `InventoryConfiguration` property type specifies the inventory configuration for an Amazon S3 bucket.

For more information, see GET Bucket inventory in the *Amazon Simple Storage Service API Reference*

`InventoryConfiguration` is a property of the AWS::S3::Bucket (p. 1985) resource type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Destination" : Destination (p. 2009),
  "Enabled" : Boolean,
  "Id" : String,
  "IncludedObjectVersions" : String,
  "OptionalFields" : [ String, ... ]
  "Prefix" : String,
  "ScheduleFrequency" : String
}
```

YAML

```
Destination: Destination
Enabled: Boolean
Id: String
IncludedObjectVersions: String
OptionalFields:
```

```
  - String
Prefix: String
ScheduleFrequency: String
```

Properties

`Destination`

Information about where to publish the inventory results.

Required: Yes

Type: Destination (p. 2009)

Update requires: No interruption (p. 120)

`Enabled`

Specifies whether the inventory is enabled or disabled. If set to `True`, an inventory list is generated. If set to `False`, no inventory list is generated.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

`Id`

The ID that identifies the inventory configuration.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`IncludedObjectVersions`

Object versions to include in the inventory list. If set to `All`, the list includes all the object versions, which adds the version related fields `VersionId`, `IsLatest`, and `DeleteMarker` to the list. If set to `Current`, the list does not contain these version related fields.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`OptionalFields`

The optional fields that are included in the inventory results.

Required: No

Type: StringList

Update requires: No interruption (p. 120)

`Prefix`

The prefix that is prepended to all inventory results.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ScheduleFrequency`

The frequency of inventory results generation.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Simple Storage Service Bucket LambdaConfiguration

`LambdaConfigurations` is a property of the Amazon S3 Bucket NotificationConfiguration (p. 2017) property that describes the AWS Lambda (Lambda) functions to invoke and the events for which to invoke them.

Syntax

JSON

```
{
  "Event" : String,
  "Filter" : Filter,
  "Function" : String
}
```

YAML

```
Event: String
Filter:
  Filter
Function: String
```

Properties

`Event`

The S3 bucket event for which to invoke the Lambda function. For more information, see Supported Event Types in the *Amazon Simple Storage Service Developer Guide*.

Required: Yes

Type: String

`Filter`

The filtering rules that determine which objects invoke the Lambda function. For example, you can create a filter so that only image files with a `.jpg` extension invoke the function when they are added to the S3 bucket.

Required: No

Type: Amazon S3 Bucket NotificationFilter (p. 2018)

`Function`

The Amazon Resource Name (ARN) of the Lambda function that Amazon S3 invokes when the specified event type occurs.

Required: Yes

Type: String

Example

The following example creates a `NotificationConfiguration` for Lambda using an S3 bucket named `EncryptionServiceBucket`.

> **Note**
> The `BucketName` is unique and the `Value` contains a file extension without a period (`.`).

JSON

```
"EncryptionServiceBucket" : {
  "Type" : "AWS::S3::Bucket",
  "Properties" : {
    "BucketName" : { "Fn::Sub" : "${User}-encryption-service" },
    "NotificationConfiguration" : {
      "LambdaConfigurations" : [{
        "Function" : { "Ref" : "LambdaDeploymentArn" },
        "Event" : "s3:ObjectCreated:*",
        "Filter" : {
          "S3Key" : {
            "Rules" : [{
              "Name" : "suffix",
              "Value" : "zip"
            }]
          }
        }
      }]
    }
  }
}
```

YAML

```
EncryptionServiceBucket:
  Type: AWS::S3::Bucket
  Properties:
    BucketName: !Sub ${User}-encryption-service
    NotificationConfiguration:
      LambdaConfigurations:
        -
          Function: !Ref LambdaDeploymentArn
          Event: "s3:ObjectCreated:*"
          Filter:
            S3Key:
              Rules:
                -
                  Name: suffix
                  Value: zip
```

Amazon S3 Bucket LifecycleConfiguration

Describes the lifecycle configuration for objects in an AWS::S3::Bucket (p. 1985) resource.

Syntax

JSON

```
{
```

```
  "Rules" : [ Lifecycle Rule, ... ]
}
```

YAML

```
Rules:
  - Lifecycle Rule
```

Properties

`Rules`

A lifecycle rule for individual objects in an S3 bucket.

Required: Yes

Type: Amazon S3 Bucket Rule (p. 2026)

Amazon S3 Bucket LoggingConfiguration

Describes where logs are stored and the prefix that Amazon S3 assigns to all log object keys for an AWS::S3::Bucket (p. 1985) resource. These logs track requests to an Amazon S3 bucket. For more information, see PUT Bucket logging in the *Amazon Simple Storage Service API Reference*.

Syntax

JSON

```
{
  "DestinationBucketName" : String,
  "LogFilePrefix" : String
}
```

YAML

```
DestinationBucketName: String
LogFilePrefix: String
```

Properties

`DestinationBucketName`

The name of an Amazon S3 bucket where Amazon S3 store server access log files. You can store log files in any bucket that you own. By default, logs are stored in the bucket where the `LoggingConfiguration` property is defined.

Required: No

Type: String

`LogFilePrefix`

A prefix for the all log object keys. If you store log files from multiple Amazon S3 buckets in a single bucket, you can use a prefix to distinguish which log files came from which bucket.

Required: No

Type: String

Amazon S3 Bucket MetricsConfiguration

The `MetricsConfiguration` property type specifies a metrics configuration for the CloudWatch request metrics (specified by the metrics configuration ID) from an Amazon S3 bucket. If you're updating an existing metrics configuration, note that this is a full replacement of the existing metrics configuration. If you don't include the elements you want to keep, they are erased. For more information, see PUT Bucket metrics in the *Amazon Simple Storage Service (Amazon S3) API Reference*.

`MetricsConfiguration` is a property of the AWS::S3::Bucket (p. 1985) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Id" : String,
  "Prefix" : String,
  "TagFilters" : [ TagFilter (p. 2033), ... ]
}
```

YAML

```
Id: String
Prefix: String
TagFilters:
  - TagFilter (p. 2033)
```

Properties

For more information and valid values, see PUT Bucket metrics in the *Amazon Simple Storage Service (Amazon S3) API Reference*.

`Id`

The ID used to identify the metrics configuration.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Prefix`

The prefix that an object must have to be included in the metrics results.

Required: No

Type: String

Update requires: No interruption (p. 120)

`TagFilters`

Specifies a list of tag filters to use as a metrics configuration filter. The metrics configuration includes only objects that meet the filter's criteria.

Required: No

Type: List of TagFilter (p. 2033)

Update requires: No interruption (p. 120)

Amazon S3 Bucket NoncurrentVersionTransition

`NoncurrentVersionTransition` is a property of the Amazon S3 Bucket Rule (p. 2026) property that describes when noncurrent objects transition to a specified storage class.

Syntax

JSON

```
{
  "StorageClass" : String,
  "TransitionInDays" : Integer
}
```

YAML

```
StorageClass: String
TransitionInDays: Integer
```

Properties

`StorageClass`

The storage class to which you want the object to transition, such as `GLACIER`. For valid values, see the `StorageClass` request element of the PUT Bucket lifecycle action in the *Amazon Simple Storage Service API Reference*.

Required: Yes

Type: String

`TransitionInDays`

The number of days between the time that a new version of the object is uploaded to the bucket and when old versions of the object are transitioned to the specified storage class.

Required: Yes

Type: Integer

Amazon S3 Bucket NotificationConfiguration

Describes the notification configuration for an AWS::S3::Bucket (p. 1985) resource.

Note
If you create the target resource and related permissions in the same template, you might have a circular dependency.
For example, you might use the AWS::Lambda::Permission resource to grant the S3 bucket to invoke a Lambda function. However, AWS CloudFormation can't create the S3 bucket until the bucket has permission to invoke the function (AWS CloudFormation checks if the S3 bucket can invoke the function). If you're using Refs to pass the bucket name, this leads to a circular dependency.
To avoid this dependency, you can create all resources without specifying the notification configuration. Then, update the stack with a notification configuration.

Syntax

JSON

```
{
  "LambdaConfigurations" : [ Lambda Configuration, ... ],
  "QueueConfigurations" : [ Queue Configuration, ... ],
  "TopicConfigurations" : [ Topic Configuration, ... ]
}
```

YAML

```
LambdaConfigurations:
  - Lambda Configuration
QueueConfigurations:
  - Queue Configuration
TopicConfigurations:
  - Topic Configuration
```

Properties

`LambdaConfigurations`

The AWS Lambda functions to invoke and the events for which to invoke the functions.

Required: No

Type: LambdaConfiguration (p. 2013)

`QueueConfigurations`

The Amazon Simple Queue Service queues to publish messages to and the events for which to publish messages.

Required: No

Type: QueueConfiguration (p. 2019)

`TopicConfigurations`

The topic to which notifications are sent and the events for which notification are generated.

Required: No

Type: TopicConfiguration (p. 2034)

Amazon S3 Bucket NotificationFilter

`Filter` is a property of the `LambdaConfigurations` (p. 2013), `QueueConfigurations` (p. 2019), and `TopicConfigurations` (p. 2034) properties that describes the filtering rules that determine the Amazon Simple Storage Service (Amazon S3) objects for which to send notifications.

Syntax

JSON

```
{
  "S3Key" : S3 Key
}
```

YAML

```
S3Key:
  S3 Key
```

Properties

`S3Key`

Amazon S3 filtering rules that describe for which object key names to send notifications.

Required: Yes

Type: Amazon S3 Bucket S3KeyFilter (p. 2029)

Amazon Simple Storage Service Bucket QueueConfiguration

`QueueConfigurations` is a property of the Amazon S3 Bucket NotificationConfiguration (p. 2017) property that describes the S3 bucket events about which you want to send messages to Amazon SQS and the queues to which you want to send them.

Syntax

JSON

```
{
  "Event" : String,
  "Filter" : Filter,
  "Queue" : String
}
```

YAML

```
Event: String
Filter:
  Filter
Queue: String
```

Properties

`Event`

The S3 bucket event about which you want to publish messages to Amazon Simple Queue Service (Amazon SQS). For more information, see Supported Event Types in the *Amazon Simple Storage Service Developer Guide*.

Required: Yes

Type: String

`Filter`

The filtering rules that determine for which objects to send notifications. For example, you can create a filter so that Amazon Simple Storage Service (Amazon S3) sends notifications only when image files with a `.jpg` extension are added to the bucket.

Required: No

Type: Amazon S3 Bucket NotificationFilter (p. 2018)

`Queue`

The Amazon Resource Name (ARN) of the Amazon SQS queue that Amazon S3 publishes messages to when the specified event type occurs.

Required: Yes

Type: String

Amazon S3 Website Configuration Redirect All Requests To Property

The `RedirectAllRequestsTo` code is an embedded property of the Amazon S3 Website Configuration Property (p. 2036) property that describes the redirect behavior of all requests to a website endpoint of an Amazon S3 bucket.

Syntax

JSON

```
{
  "HostName" : String,
  "Protocol" : String
}
```

YAML

```
HostName: String
Protocol: String
```

Properties

`HostName`

Name of the host where requests are redirected.

Required: Yes

Type: String

`Protocol`

Protocol to use (`http` or `https`) when redirecting requests. The default is the protocol that is used in the original request.

Required: No

Type: String

Amazon S3 Website Configuration Routing Rules Redirect Rule Property

The `RedirectRule` property is an embedded property of the Amazon S3 Website Configuration Routing Rules Property (p. 2026) that describes how requests are redirected. In the event of an error, you can specify a different error code to return.

Syntax

JSON

```
{
```

```
  "HostName" : String,
  "HttpRedirectCode" : String,
  "Protocol" : String,
  "ReplaceKeyPrefixWith" : String,
  "ReplaceKeyWith" : String
}
```

YAML

```
HostName: String
HttpRedirectCode: String
Protocol: String
ReplaceKeyPrefixWith: String
ReplaceKeyWith: String
```

Properties

`HostName`

Name of the host where requests are redirected.

Required: No

Type: String

`HttpRedirectCode`

The HTTP redirect code to use on the response.

Required: No

Type: String

`Protocol`

The protocol to use in the redirect request.

Required: No

Type: String

`ReplaceKeyPrefixWith`

The object key prefix to use in the redirect request. For example, to redirect requests for all pages with the prefix `docs/` (objects in the `docs/` folder) to the `documents/` prefix, you can set the `KeyPrefixEquals` property in routing condition property to `docs/`, and set the *ReplaceKeyPrefixWith* property to `documents/`.

> **Important**
> If you specify this property, you cannot specify the `ReplaceKeyWith` property.

Required: No

Type: String

`ReplaceKeyWith`

The specific object key to use in the redirect request. For example, redirect request to `error.html`.

> **Important**
> If you specify this property, you cannot specify the `ReplaceKeyPrefixWith` property.

Required: No

Type: String

Amazon S3 Bucket ReplicationConfiguration

`ReplicationConfiguration` is a property of the AWS::S3::Bucket (p. 1985) resource that specifies replication rules and the AWS Identity and Access Management (IAM) role Amazon Simple Storage Service (Amazon S3) uses to replicate objects.

Syntax

JSON

```
{
  "Role" : String,
  "Rules" : [ Rule, ... ]
}
```

YAML

```
Role: String
Rules:
  - Rule
```

Properties

`Role`

The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role that Amazon S3 assumes when replicating objects. For more information, see How to Set Up Cross-Region Replication in the *Amazon Simple Storage Service Developer Guide*.

Required: Yes

Type: String

`Rules`

A replication rule that specifies which objects to replicate and where they are stored.

Required: Yes

Type: List of Amazon S3 Bucket ReplicationRule (p. 2024)

Amazon S3 Bucket ReplicationDestination

`Destination` is a property of the Amazon S3 Bucket ReplicationRule (p. 2024) property that specifies which Amazon Simple Storage Service (Amazon S3) bucket to store replicated objects and their storage class.

Syntax

JSON

```
{
  "AccessControlTranslation" : AccessControlTranslation (p. 2004),
  "Account" : String,
  "Bucket" : String,
  "EncryptionConfiguration" : EncryptionConfiguration (p. 2010),
```

```
  "StorageClass" : String
}
```

YAML

```
AccessControlTranslation: AccessControlTranslation (p. 2004)
Account: String
Bucket: String
EncryptionConfiguration: EncryptionConfiguration (p. 2010)
StorageClass: String
```

Properties

`AccessControlTranslation`

Specify this only in a cross-account scenario (where source and destination bucket owners are not the same), and you want to change replica ownership to the AWS account that owns the destination bucket. If this is not specified in the replication configuration, the replicas are owned by same AWS account that owns the source object.

Required: No

Type: Amazon S3 Bucket AccessControlTranslation (p. 2004)

`Account`

Destination bucket owner account ID. In a cross-account scenario, if you direct Amazon S3 to change replica ownership to the AWS account that owns the destination bucket by specifying the `AccessControlTranslation` property, this is the account ID of the destination bucket owner. For more information, see Cross-Region Replication Additional Configuration: Change Replica Owner in the *Amazon Simple Storage Service Developer Guide*.

Conditional: If you specify the `AccessControlTranslation` property, the `Account` property is required.

Required: No

Type: String

`Bucket`

The Amazon resource name (ARN) of an S3 bucket where Amazon S3 stores replicated objects. This destination bucket must be in a different region than your source bucket.

If you have multiple rules in your replication configuration, specify the same destination bucket for all of the rules.

Required: Yes

Type: String

`EncryptionConfiguration`

Specifies encryption-related information.

Required: No

Type: Amazon S3 Bucket EncryptionConfiguration (p. 2010)

`StorageClass`

The storage class to use when replicating objects, such as standard or reduced redundancy. By default, Amazon S3 uses the storage class of the source object to create object replica. For valid

values, see the `StorageClass` element of the PUT Bucket replication action in the *Amazon Simple Storage Service API Reference*.

Required: No

Type: String

Amazon S3 Bucket ReplicationRule

The `ReplicationRule` property type specifies which Amazon Simple Storage Service (Amazon S3) objects to replicate and where to store them. The `Rules` subproperty of the Amazon S3 Bucket ReplicationConfiguration (p. 2022) property contains a list of `ReplicationRule` property types.

Syntax

JSON

```
{
  "Destination" : ReplicationDestination (p. 2022),
  "Id" : String,
  "Prefix" : String,
  "SourceSelectionCriteria" : SourceSelectionCriteria (p. 2031),
  "Status" : String
}
```

YAML

```
Destination:
  ReplicationDestination (p. 2022)
Id: String
Prefix: String
SourceSelectionCriteria: SourceSelectionCriteria (p. 2031)
Status: String
```

Properties

`Destination`

Defines the destination where Amazon S3 stores replicated objects.

Required: Yes

Type: Amazon S3 Bucket ReplicationDestination (p. 2022)

`Id`

A unique identifier for the rule. If you don't specify a value, AWS CloudFormation generates a random ID.

Required: No

Type: String

`Prefix`

An object prefix. This rule applies to all Amazon S3 objects with this prefix. To specify all objects in an S3 bucket, specify an empty string.

Required: Yes

Type: String

`SourceSelectionCriteria`

Specifies additional filters in identifying source objects that you want to replicate.

Currently, Amazon S3 supports only the filter that you can specify for objects created with server-side encryption using an AWS KMS-managed key. That is, you can choose to enable or disable replication of these objects.

Required: No

Type: Amazon S3 Bucket SourceSelectionCriteria (p. 2031)

`Status`

Whether the rule is enabled. For valid values, see the `Status` element of the PUT Bucket replication action in the *Amazon Simple Storage Service API Reference*.

Required: Yes

Type: String

Amazon S3 Website Configuration Routing Rules Routing Rule Condition Property

The `RoutingRuleCondition` property is an embedded property of the Amazon S3 Website Configuration Routing Rules Property (p. 2026) that describes a condition that must be met for a redirect to apply.

Syntax

JSON

```
{
  "HttpErrorCodeReturnedEquals" : String,
  "KeyPrefixEquals" : String
}
```

YAML

```
HttpErrorCodeReturnedEquals: String
KeyPrefixEquals: String
```

Properties

`HttpErrorCodeReturnedEquals`

Applies this redirect if the error code equals this value in the event of an error.

Required: Conditional. You must specify at least one condition property.

Type: String

`KeyPrefixEquals`

The object key name prefix when the redirect is applied. For example, to redirect requests for `ExamplePage.html`, set the key prefix to `ExamplePage.html`. To redirect request for all pages with the prefix `docs/`, set the key prefix to `docs/`, which identifies all objects in the `docs/` folder.

Required: Conditional. You must at least one condition property.

Type: String

Amazon S3 Website Configuration Routing Rules Property

The `RoutingRules` property is an embedded property of the Amazon S3 Website Configuration Property (p. 2036) property. This property describes the redirect behavior and when a redirect is applied.

Syntax

JSON

```
{
  "RedirectRule" : Redirect rule,
  "RoutingRuleCondition" : Routing rule condition
}
```

YAML

```
RedirectRule:
  Redirect rule
RoutingRuleCondition:
  Routing rule condition
```

Properties

`RedirectRule`

Redirect requests to another host, to another page, or with another protocol.

Required: Yes

Type: Amazon S3 Website Configuration Routing Rules Redirect Rule Property (p. 2020)

`RoutingRuleCondition`

Rules that define when a redirect is applied.

Required: No

Type: Amazon S3 Website Configuration Routing Rules Routing Rule Condition Property (p. 2025)

Amazon S3 Bucket Rule

The `Rule` property type describes lifecycle rules. The `Rules` subproperty of the Amazon S3 Bucket LifecycleConfiguration (p. 2014) property contains a list of `Rule` property types. For more information, see PUT Bucket lifecycle in the *Amazon Simple Storage Service (Amazon S3) API Reference*.

Syntax

JSON

```
{
  "AbortIncompleteMultipartUpload" : AbortIncompleteMultipartUpload,
  "ExpirationDate" : String,
  "ExpirationInDays" : Integer,
  "Id" : String,
  "NoncurrentVersionExpirationInDays" : Integer,
```

```
  "NoncurrentVersionTransition (deprecated)" : NoncurrentVersionTransition,
  "NoncurrentVersionTransitions" : [ NoncurrentVersionTransition, ... ],
  "Prefix" : String,
  "Status" : String,
  "TagFilters" : [ TagFilter (p. 2033), ... ],
  "Transition (deprecated)" : Transition,
  "Transitions" : [ Transition, ... ]
}
```

YAML

```
AbortIncompleteMultipartUpload:
  AbortIncompleteMultipartUpload
ExpirationDate: String
ExpirationInDays: Integer
Id: String
NoncurrentVersionExpirationInDays: Integer
NoncurrentVersionTransition (deprecated):
  NoncurrentVersionTransition
NoncurrentVersionTransitions:
  - NoncurrentVersionTransition
Prefix: String
Status: String
TagFilters:
  - TagFilter (p. 2033)
Transition (deprecated):
  Transition
Transitions:
  - Transition
```

Properties

`AbortIncompleteMultipartUpload`

Specifies a lifecycle rule that aborts incomplete multipart uploads to an Amazon S3 bucket.

Required: Conditional. You must specify at least one of the following properties: `AbortIncompleteMultipartUpload`, `ExpirationDate`, `ExpirationInDays`, `NoncurrentVersionExpirationInDays`, `NoncurrentVersionTransition`, `NoncurrentVersionTransitions`, `Transition`, or `Transitions`.

Type: Amazon S3 Bucket AbortIncompleteMultipartUpload (p. 2002)

`ExpirationDate`

Indicates when objects are deleted from Amazon S3 and Amazon Glacier. The date value must be in ISO 8601 format. The time is always midnight UTC. If you specify an expiration and transition time, you must use the same time unit for both properties (either in days or by date). The expiration time must also be later than the transition time.

Required: Conditional. You must specify at least one of the following properties: `AbortIncompleteMultipartUpload`, `ExpirationDate`, `ExpirationInDays`, `NoncurrentVersionExpirationInDays`, `NoncurrentVersionTransition`, `NoncurrentVersionTransitions`, `Transition`, or `Transitions`.

Type: String

`ExpirationInDays`

Indicates the number of days after creation when objects are deleted from Amazon S3 and Amazon Glacier. If you specify an expiration and transition time, you must use the same time unit for both properties (either in days or by date). The expiration time must also be later than the transition time.

Required: Conditional. You must specify at least one of the following properties: `AbortIncompleteMultipartUpload`, `ExpirationDate`, `ExpirationInDays`, `NoncurrentVersionExpirationInDays`, `NoncurrentVersionTransition`, `NoncurrentVersionTransitions`, `Transition`, or `Transitions`.

Type: Integer

`Id`

A unique identifier for this rule. The value cannot be more than 255 characters.

Required: No

Type: String

`NoncurrentVersionExpirationInDays`

For buckets with versioning enabled (or suspended), specifies the time, in days, between when a new version of the object is uploaded to the bucket and when old versions of the object expire. When object versions expire, Amazon S3 permanently deletes them. If you specify a transition and expiration time, the expiration time must be later than the transition time.

Required: Conditional. You must specify at least one of the following properties: `AbortIncompleteMultipartUpload`, `ExpirationDate`, `ExpirationInDays`, `NoncurrentVersionExpirationInDays`, `NoncurrentVersionTransition`, `NoncurrentVersionTransitions`, `Transition`, or `Transitions`.

Type: Integer

`NoncurrentVersionTransition` (deprecated)

For buckets with versioning enabled (or suspended), specifies when non-current objects transition to a specified storage class. If you specify a transition and expiration time, the expiration time must be later than the transition time. If you specify this property, don't specify the `NoncurrentVersionTransitions` property.

Required: Conditional. You must specify at least one of the following properties: `AbortIncompleteMultipartUpload`, `ExpirationDate`, `ExpirationInDays`, `NoncurrentVersionExpirationInDays`, `NoncurrentVersionTransition`, `NoncurrentVersionTransitions`, `Transition`, or `Transitions`.

Type: Amazon S3 Bucket NoncurrentVersionTransition (p. 2017)

`NoncurrentVersionTransitions`

For buckets with versioning enabled (or suspended), one or more transition rules that specify when non-current objects transition to a specified storage class. If you specify a transition and expiration time, the expiration time must be later than the transition time. If you specify this property, don't specify the `NoncurrentVersionTransition` property.

Required: Conditional. You must specify at least one of the following properties: `AbortIncompleteMultipartUpload`, `ExpirationDate`, `ExpirationInDays`, `NoncurrentVersionExpirationInDays`, `NoncurrentVersionTransition`, `NoncurrentVersionTransitions`, `Transition`, or `Transitions`.

Type: List of Amazon S3 Bucket NoncurrentVersionTransition (p. 2017)

`Prefix`

Object key prefix that identifies one or more objects to which this rule applies.

Required: No

Type: String

`Status`

Specify either `Enabled` or `Disabled`. If you specify `Enabled`, Amazon S3 executes this rule as scheduled. If you specify `Disabled`, Amazon S3 ignores this rule.

Required: Yes

Type: String

`TagFilters`

Tags to use to identify a subset of objects to which the lifecycle rule applies.

Required: No

Type: List of TagFilter (p. 2033)

Update requires: No interruption (p. 120)

`Transition` (deprecated)

Specifies when an object transitions to a specified storage class. If you specify an expiration and transition time, you must use the same time unit for both properties (either in days or by date). The expiration time must also be later than the transition time. If you specify this property, don't specify the `Transitions` property.

Required: Conditional. You must specify at least one of the following properties: `AbortIncompleteMultipartUpload`, `ExpirationDate`, `ExpirationInDays`, `NoncurrentVersionExpirationInDays`, `NoncurrentVersionTransition`, `NoncurrentVersionTransitions`, `Transition`, or `Transitions`.

Type: Amazon S3 Bucket Transition (p. 2035)

`Transitions`

One or more transition rules that specify when an object transitions to a specified storage class. If you specify an expiration and transition time, you must use the same time unit for both properties (either in days or by date). The expiration time must also be later than the transition time. If you specify this property, don't specify the `Transition` property.

Required: Conditional. You must specify at least one of the following properties: `AbortIncompleteMultipartUpload`, `ExpirationDate`, `ExpirationInDays`, `NoncurrentVersionExpirationInDays`, `NoncurrentVersionTransition`, `NoncurrentVersionTransitions`, `Transition`, or `Transitions`.

Type: List of Amazon S3 Bucket Transition (p. 2035)

Amazon S3 Bucket S3KeyFilter

`S3Key` is a property of the Amazon S3 Bucket NotificationFilter (p. 2018) property that specifies the key names of Amazon Simple Storage Service (Amazon S3) objects for which to send notifications.

Syntax

JSON

```
{
  "Rules" : [ Rule, ... ]
}
```

YAML

```
Rules:
  - Rule
```

Properties

`Rules`

The object key name to filter on and whether to filter on the suffix or prefix of the key name.

Required: Yes

Type: List of Amazon S3 Bucket FilterRule (p. 2010)

Amazon S3 Bucket ServerSideEncryptionByDefault

The `ServerSideEncryptionByDefault` property is part of the AWS::S3::Bucket (p. 1985) resource that specifies the server-side encryption by default. For more information, see PUT Bucket encryption in the *Amazon Simple Storage Service API Reference*.

Syntax

JSON

```
{
  "KMSMasterKeyID" : String,
  "SSEAlgorithm" : String
}
```

YAML

```
KMSMasterKeyID: String
SSEAlgorithm: String
```

Properties

`KMSMasterKeyID`

The AWS KMS master key ID used for the SSE-KMS encryption.

Constraint: Can only be used when you set the value of `SSEAlgorithm` as `aws:kms`. The default aws/s3 AWS KMS master key is used if this property is absent while `SSEAlgorithm` is `aws:kms`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SSEAlgorithm`

The server-side encryption algorithm to use. Valid values include `AES256` and `aws:kms`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon S3 Bucket ServerSideEncryptionRule

The `ServerSideEncryptionRule` property is part of the AWS::S3::Bucket (p. 1985) resource that specifies the server-side encryption by default configuration. For more information, see PUT Bucket encryption in the *Amazon Simple Storage Service API Reference*.

Syntax

JSON

```
{
  "ServerSideEncryptionByDefault" : ServerSideEncryptionByDefault (p. 2030)
}
```

YAML

```
ServerSideEncryptionByDefault:
 ServerSideEncryptionByDefault (p. 2030)
```

Properties

`ServerSideEncryptionByDefault`

Sets server-side encryption by default.

Required: No

Type: ServerSideEncryptionByDefault (p. 2030)

Update requires: No interruption (p. 120)

Amazon S3 Bucket SourceSelectionCriteria

The `SourceSelectionCriteria` property type specifies additional filters in identifying source objects that you want to replicate.

Currently, Amazon S3 supports only the filter that you can specify for objects created with server-side encryption using an AWS KMS-managed key. That is, you can choose to enable or disable replication of these objects.

`SourceSelectionCriteria` is a property of the AWS::S3::Bucket (p. 1985) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "SseKmsEncryptedObjects" : SseKmsEncryptedObjects (p. 2032)
}
```

YAML

```
SseKmsEncryptedObjects: SseKmsEncryptedObjects (p. 2032)
```

Properties

`SseKmsEncryptedObjects`

Contains the status of whether Amazon S3 replicates objects created with server-side encryption using an AWS KMS-managed key.

Required: Yes

Type: Amazon S3 Bucket SseKmsEncryptedObjects (p. 2032)

Update requires: No interruption (p. 120)

Amazon S3 Bucket SseKmsEncryptedObjects

The `SseKmsEncryptedObjects` property type specifies the status of whether Amazon S3 replicates objects created with server-side encryption using an AWS KMS-managed key.

`SseKmsEncryptedObjects` is a property of the AWS::S3::Bucket (p. 1985) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Status" : String
}
```

YAML

```
Status: String
```

Properties

`Status`

Specifies whether Amazon S3 replicates objects created with server-side encryption using an AWS KMS-managed key. Valid values include `Enabled` and `Disabled`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon S3 Bucket StorageClassAnalysis

The `StorageClassAnalysis` property type specifies data related to access patterns to be collected and made available to analyze the tradeoffs between different storage classes for an Amazon S3 bucket.

`StorageClassAnalysis` is a property of the Amazon S3 Bucket AnalyticsConfiguration (p. 2004) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "DataExport" : DataExport (p. 2008)
}
```

YAML

```
DataExport: DataExport
```

Properties

`DataExport`

Describes how data related to the storage class analysis should be exported.

Required: No

Type: Amazon S3 Bucket DataExport (p. 2008)

Update requires: No interruption (p. 120)

Amazon S3 Bucket TagFilter

The `TagFilter` property type specifies tags to use to identify a subset of objects for an Amazon S3 bucket.

The `TagFilters` property of the AWS::S3::Bucket (p. 1985) property type contains a list of `TagFilter` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Key" : String,
  "Value" : String
}
```

YAML

```
Key: String
Value: String
```

Properties

`Key`

The tag key.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Value`

The tag value.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Amazon Simple Storage Service Bucket TopicConfiguration

Describes the topic and events for the Amazon S3 Bucket NotificationConfiguration (p. 2017) property.

Syntax

JSON

```
{
  "Event" : String,
  "Filter" : Filter,
  "Topic" : String
}
```

YAML

```
Event: String
Filter:
  Filter
Topic: String
```

Properties

`Event`

The Amazon Simple Storage Service (Amazon S3) bucket event about which to send notifications. For more information, see Supported Event Types in the *Amazon Simple Storage Service Developer Guide*.

Required: Yes

Type: String

`Filter`

The filtering rules that determine for which objects to send notifications. For example, you can create a filter so that Amazon Simple Storage Service (Amazon S3) sends notifications only when image files with a `.jpg` extension are added to the bucket.

Required: No

Type: Amazon S3 Bucket NotificationFilter (p. 2018)

`Topic`

The Amazon SNS topic Amazon Resource Name (ARN) to which Amazon S3 reports the specified events.

Required: Yes

Type: String

Amazon S3 Bucket Transition

Describes when an object transitions to a specified storage class for the Amazon S3 Bucket Rule (p. 2026) property.

Syntax

JSON

```
{
  "StorageClass" : String,
  "TransitionDate" : String,
  "TransitionInDays" : Integer
}
```

YAML

```
StorageClass: String
TransitionDate: String
TransitionInDays: Integer
```

Properties

`StorageClass`

The storage class to which you want the object to transition, such as `GLACIER`. For valid values, see the `StorageClass` request element of the PUT Bucket lifecycle action in the *Amazon Simple Storage Service API Reference*.

Required: Yes

Type: String

`TransitionDate`

Indicates when objects are transitioned to the specified storage class. The date value must be in ISO 8601 format. The time is always midnight UTC.

Required: Conditional

Type: String

`TransitionInDays`

Indicates the number of days after creation when objects are transitioned to the specified storage class.

Required: Conditional

Type: Integer

Amazon S3 Bucket VersioningConfiguration

Describes the versioning state of an AWS::S3::Bucket (p. 1985) resource. For more information, see PUT Bucket versioning in the *Amazon Simple Storage Service API Reference*.

Syntax

JSON

```
{
  "Status" : String
}
```

YAML

```
Status: String
```

Properties

`Status`

The versioning state of an Amazon S3 bucket. If you enable versioning, you must suspend versioning to disable it.

Valid values include `Enabled` and `Suspended`. The default is `Suspended`.

Required: Yes

Type: String

Amazon S3 Website Configuration Property

`WebsiteConfiguration` is an embedded property of the AWS::S3::Bucket (p. 1985) resource.

Syntax

JSON

```
{
  "ErrorDocument" : String,
  "IndexDocument" : String,
  "RedirectAllRequestsTo" : Redirect all requests rule,
  "RoutingRules" : [ Routing rule, ... ]
}
```

YAML

```
ErrorDocument: String
IndexDocument: String
RedirectAllRequestsTo:
  Redirect all requests rule
RoutingRules:
  - Routing rule
```

Properties

`ErrorDocument`

The name of the error document for the website.

Required: No

Type: String

`IndexDocument`

The name of the index document for the website.

Required: Yes

Type: String

`RedirectAllRequestsTo`

The redirect behavior for every request to this bucket's website endpoint.

> **Important**
> If you specify this property, you cannot specify any other property.

Required: No

Type: Amazon S3 Website Configuration Redirect All Requests To Property (p. 2020)

`RoutingRules`

Rules that define when a redirect is applied and the redirect behavior.

Required: No

Type: List of Amazon S3 Website Configuration Routing Rules Property (p. 2026)

Example

```
"S3Bucket" : {
   "Type" : "AWS::S3::Bucket",
   "Properties" : {
      "AccessControl" : "PublicRead",
      "WebsiteConfiguration" : {
         "IndexDocument" : "index.html",
         "ErrorDocument" : "error.html"
      }
   }
}
```

AWS::S3::BucketPolicy

The AWS::S3::BucketPolicy type applies an Amazon S3 bucket policy to an Amazon S3 bucket.

AWS::S3::BucketPolicy Snippet: Declaring an Amazon S3 Bucket Policy (p. 400)

Topics

- Syntax (p. 2038)
- Properties (p. 2038)
- Examples (p. 2038)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::S3::BucketPolicy",
   "Properties" : {
      "Bucket" : String,
      "PolicyDocument" : JSON
   }
}
```

YAML

```
Type: AWS::S3::BucketPolicy
Properties:
  Bucket: String
  PolicyDocument: JSON
```

Properties

`Bucket`

The name of the Amazon S3 bucket to which the policy applies.

Required: Yes

Type: String

You cannot update this property. If you want to add or remove a bucket from a bucket policy, you must modify your AWS CloudFormation template by creating a new bucket policy resource and removing the old one. Then use the modified template to update your AWS CloudFormation stack.

`PolicyDocument`

A policy document containing permissions to add to the specified bucket. For more information, see Access Policy Language Overview in the *Amazon Simple Storage Service Developer Guide*.

Required: Yes

Type: JSON object

Update requires: No interruption (p. 120)

Examples

Bucket policy that allows GET requests from specific referers

The following sample is a bucket policy that is attached to the `myExampleBucket` bucket and allows GET requests that originate from `www.example.com` and `example.com`:

JSON

```
"SampleBucketPolicy" : {
  "Type" : "AWS::S3::BucketPolicy",
```

```
  "Properties" : {
    "Bucket" : {"Ref" : "myExampleBucket"},
    "PolicyDocument": {
      "Statement":[{
     "Action":["s3:GetObject"],
     "Effect":"Allow",
     "Resource": { "Fn::Join" : ["", ["arn:aws:s3:::", { "Ref" : "myExampleBucket" } , "/
*" ]]},
     "Principal":"*",
        "Condition":{
          "StringLike":{
            "aws:Referer":[
              "http://www.example.com/*",
              "http://example.com/*"
            ]
          }
        }
      }]
    }
  }
}
```

YAML

```
SampleBucketPolicy:
  Type: AWS::S3::BucketPolicy
  Properties:
    Bucket:
      Ref: "myExampleBucket"
    PolicyDocument:
      Statement:
        -
          Action:
            - "s3:GetObject"
          Effect: "Allow"
          Resource:
            Fn::Join:
              - ""
              -
                - "arn:aws:s3:::"
                -
                  Ref: "myExampleBucket"
                - "/*"
          Principal: "*"
          Condition:
            StringLike:
              aws:Referer:
                - "http://www.example.com/*"
                - "http://example.com/*"
```

Amazon SageMaker Resource Types Reference

This section contains reference information for all Amazon SageMaker resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::SageMaker::data-type-name
```

Topics

- AWS::SageMaker::Endpoint (p. 2040)
- AWS::SageMaker::EndpointConfig (p. 2044)
- AWS::SageMaker::Model (p. 2050)
- AWS::SageMaker::NotebookInstance (p. 2057)
- AWS::SageMaker::NotebookInstanceLifecycleConfig (p. 2062)

AWS::SageMaker::Endpoint

Use the `AWS::SageMaker::Endpoint` resource to create an endpoint using the specified configuration in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models. You create the endpoint configuration with the AWS::SageMaker::EndpointConfig (p. 2044) resource. For more information, see Deploying a Model on Amazon SageMaker Hosting Services in the *SageMaker Developer Guide*.

Topics

- Syntax (p. 2040)
- Properties (p. 2040)
- Return Values (p. 2041)
- Examples (p. 2041)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SageMaker::Endpoint",
  "Properties" : {
    "EndpointName" : String,
    "EndpointConfigName" : String,
    "Tags" : [ Tag (p. 2258), ... ]
  }
}
```

YAML

```
Type: "AWS::SageMaker::Endpoint"
Properties:
  EndpointName: String
  EndpointConfigName: String
  Tags:
    - Tag (p. 2258)
```

Properties

`EndpointName`

The name of the endpoint.

Required: No

Type: String

Update requires: Replacement (p. 121)

`EndpointConfigName`

The name of the AWS::SageMaker::EndpointConfig (p. 2044) resource that specifies the configuration for the endpoint.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Tags`

An array of key-value pairs. For more information, see Using Cost Allocation Tags in the *AWS Billing and Cost Management User Guide*.

Required: Yes

Type: List of Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::SageMaker::Endpoint` resource to the intrinsic `Ref` function, the function returns the Amazon Resource Name (ARN) of the endpoint, such as `arn:aws:sagemaker:us-west-2:012345678901:endpoint/myendpoint`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`EndpointName`

The name of the endpoint, such as `MyEndpoint`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

SageMaker Endpoint Example

The following example creates an endpoint configuration from a trained model, and then creates an endpoint.

JSON

```
{
  "Description": "Basic Hosting entities test.  We need models to create endpoint
 configs.",
  "Mappings": {
    "RegionMap": {
      "us-west-2": {
        "NullTransformer": "12345678901.dkr.ecr.us-west-2.amazonaws.com/mymodel:latest"
      },
```

```
      "us-east-2": {
        "NullTransformer": "12345678901.dkr.ecr.us-east-2.amazonaws.com/mymodel:latest"
      },
      "us-east-1": {
        "NullTransformer": "12345678901.dkr.ecr.us-east-1.amazonaws.com/mymodel:latest"
      },
      "eu-west-1": {

AWS::SageMaker::EndpointConfig

The `AWS::SageMaker::EndpointConfig` resource creates a configuration for an Amazon SageMaker endpoint. For more information, see CreateEndpointConfig in the *SageMaker Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SageMaker::EndpointConfig",
```

```
  "Properties" : {
    "ProductionVariants" : [ ProductionVariants (p. 2049), ... ]
    "EndpointConfigName" : String,
    "KmsKeyId" : String,
    "Tags" : [ Tag (p. 2258), ... ]
  }
}
```

YAML

```
Type: "AWS::SageMaker::EndpointConfig"
Properties:
  ProductionVariants:
    - ProductionVariants (p. 2049)
  EndpointConfigName: String
  KmsKeyId: String
  Tags:
    - Tag (p. 2258)
```

Properties

`ProductionVariants`

A list of the production variants that specify the models you want to host at this endpoint.

Required: Yes

Type: List of Amazon SageMaker EndpointConfig ProductionVariant (p. 2049)

Update requires: Replacement (p. 121)

`EndpointConfigName`

The name of the endpoint configuration.

Required: No

Type: String

Update requires: Replacement (p. 121)

`KmsKeyId`

If you provide a AWS KMS key ID, Amazon SageMaker uses it to encrypt data at rest on the ML storage volume that is attached to your notebook instance.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Tags`

An array of key-value pairs. For more information, see Using Cost Allocation Tags in the *AWS Billing and Cost Management User Guide*.

Required: Yes

Type: List of Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::SageMaker::EndpointConfig` resource to the intrinsic `Ref` function, the function returns the Amazon Resource Name (ARN) of the endpoint configuration, such as `arn:aws:sagemaker:us-west-2:012345678901:endpoint-config/myendpointconfig`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`EndpointConfigName`

The name of the endpoint confugration, such as `MyEndpointConfiguration`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

SageMaker Endpoint Example

The following example creates an endpoint configuration from a trained model, and then creates an endpoint.

JSON

```

Amazon SageMaker EndpointConfig ProductionVariant

The `ProductionVariant` property type specifies a model that you want to host and the resources to deploy for hosting it. If you are deploying multiple models, tell Amazon SageMaker how to distribute traffic among the models by specifying variant weights.

`ProductionVariant` is a property of the AWS::SageMaker::EndpointConfig (p. 2044) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ModelName" : String,
  "VariantName" : String,
  "InitialInstanceCount" : Integer,
  "InstanceType" : String,
  "InitialVariantWeight" : Double,
}
```

YAML

```
ModelName: String
VariantName: String
InitialInstanceCount: Integer
InstanceType: String
InitialVariantWeight: Double
```

Properties

`ModelName`

The name of the model that you want to host.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`VariantName`

The name of the production variant.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`InitialInstanceCount`

The number of instances to launch initially for this production variant.

Required: Yes

Type: Integer

Update requires: Replacement (p. 121)

`InstanceType`

The ML compute instance type to use for this production variant.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`InitialVariantWeight`

Determines initial traffic distribution among all of the models that you specify in the endpoint configuration. The traffic to a production variant is determined by the ratio of the `VariantWeight` to the sum of all `VariantWeight` values across all production variants for an endpoint. If unspecified, it defaults to 1.0.

Required: Yes

Type: Double

Update requires: Replacement (p. 121)

AWS::SageMaker::Model

The `AWS::SageMaker::Model` resource to create a model to host at an Amazon SageMaker endpoint. For more information, see Deploying a Model on Amazon SageMaker Hosting Services in the *Amazon SageMaker Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SageMaker::Model",
  "Properties" : {
    "ExecutionRoleArn" : String,
    "PrimaryContainer" : ContainerDefinition (p. 2055),
    "ModelName" : String,
    "VpcConfig" : VpcConfig (p. 2056),
    "Tags" : [ Tag (p. 2258), ... ]
  }
}
```

YAML

```
Type: "AWS::SageMaker::Model"
Properties:
  ExecutionRoleArn: String
  PrimaryContainer: ContainerDefinition (p. 2055)
  ModelName: String
  VpcConfig: VpcConfig (p. 2056)
  Tags:
    - Tag (p. 2258)
```

Properties

`ExecutionRoleArn`

The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and docker image for deployment on ML compute instances. Deploying on ML compute instances is part of model hosting. For more information, see Amazon SageMaker Roles.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`PrimaryContainer`

The location of the primary docker image containing inference code, associated artifacts, and custom environment map that the inference code uses when the model is deployed into production.

Required: Yes

Type: Amazon SageMaker Model ContainerDefinition (p. 2055)

Update requires: Replacement (p. 121)

`ModelName`

The name of the model.

Required: No

Type: String

Update requires: Replacement (p. 121)

`VpcConfig`

A VpcConfig object that specifies the VPC that you want your model to connect to. Control access to and from your model container by configuring the VPC. For more information, see Protect Models by Using an Amazon Virtual Private Cloud.

Required: No

Type: Amazon SageMaker Model VpcConfig (p. 2056)

Update requires: Replacement (p. 121)

`Tags`

An array of key-value pairs. For more information, see Using Cost Allocation Tags in the *AWS Billing and Cost Management User Guide*.

Required: No

Type: List of Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::SageMaker::Model` resource to the intrinsic `Ref` function, the function returns the Amazon Resource Name (ARN) of the model, such as `arn:aws:sagemaker:us-west-2:012345678901:model/mymodel`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`ModelName`

The name of the model, such as `MyModel`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

SageMaker Endpoint Example

The following example creates an endpoint configuration from a trained model, and then creates an endpoint.

JSON

```
{
  "Description": "Basic Hosting entities test.  We need models to create endpoint
 configs.",
  "Mappings": {
    "RegionMap": {
      "us-west-2": {
        "NullTransformer": "12345678901.dkr.ecr.us-west-2.amazonaws.com/mymodel:latest"
      },
      "us-east-2": {
        "NullTransformer": "12345678901.dkr.ecr.us-east-2.amazonaws.com/mymodel:latest"
      },
      "us-east-1": {
        "NullTransformer": "12345678901.dkr.ecr.us-east-1.amazonaws.com/mymodel:latest"
```

```
      },
      "eu-west-1": {
        "NullTransformer": "12345678901.dkr.ecr.eu-west-1.amazonaws.com/mymodel:latest"
      },

Amazon SageMaker Model ContainerDefinition

The `ContainerDefinition` property type specifies the definition of the container for a model.

`ContainerDefinition` is a property of the AWS::SageMaker::Model (p. 2050) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ContainerHostname" : String,
  "Environment" : JSON,
  "ModelDataUrl" : String,
  "Image" : String
}
```

YAML

```
ContainerHostname: String
Environment: JSON
ModelDataUrl: String
Image: String
```

Properties

`ContainerHostname`

The DNS host name for the container after Amazon SageMaker deploys it.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Environment`

The environment variables to set in the Docker container. Each key and value in the `Environment` string to string map can have length of up to 1024. We support up to 16 entries in the map.

Required: No

Type: JSON

Update requires: Replacement (p. 121)

`ModelDataUrl`

The S3 path where the model artifacts, which result from model training, are stored. This path must point to a single gzip compressed tar archive (.tar.gz suffix)

Required: No

Type: String

Update requires: Replacement (p. 121)

`Image`

The Amazon EC2 Container Registry (Amazon ECR) path where inference code is stored. If you are using your own custom algorithm instead of an algorithm provided by Amazon SageMaker, the inference code must meet Amazon SageMaker requirements. For more information, see Using Your Own Algorithms with Amazon SageMaker

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Amazon SageMaker Model VpcConfig

The `VpcConfig` property type specifies a VPC that your hosted models have access to. Control access to and from your training and model containers by configuring the VPC. For more information, see Protect Models by Using an Amazon Virtual Private Cloud.

`VpcConfig` is a property of the AWS::SageMaker::Model (p. 2050) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Subnets" : [String, ... ],
  "SecurityGroupIds: [String, ... ]
}
```

YAML

```
Subnets:
    - String
SecurityGroupIds:
    - String
```

Properties

`Subnets`

The ID of the subnets in the VPC to which you want to connect your training job or model.

Required: Yes

Type: List of String values

Update requires: Replacement (p. 121)

`SecurityGroupIds`

The VPC security group IDs, in the form sg-xxxxxxxx. Specify the security groups for the VPC that is specified in the Subnets field.

Required: Yes

Type: List of String values

Update requires: Replacement (p. 121)

AWS::SageMaker::NotebookInstance

The `AWS::SageMaker::NotebookInstance` resource Creates an Amazon SageMaker notebook instance. A notebook instance is a machine learning (ML) compute instance running on a Jupyter notebook. For more information, see Using Notebook Instances in the *Amazon SageMaker Developer Guide*.

Topics

- Syntax (p. 2058)
- Properties (p. 2058)
- Return Values (p. 2060)
- Examples (p. 2060)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SageMaker::NotebookInstance",
  "Properties" : {
    "KmsKeyId" : String,
    "DirectInternetAccess" : String,
    "SubnetId" : String,
    "NotebookInstanceName" : String,
    "InstanceType" : String,
    "LifecycleConfigName" : String,
    "SecurityGroupIds" : [ String, ... ],
    "RoleArn" : String,
    "Tags" : [ Tag (p. 2258), ... ]
  }
}
```

YAML

```
Type: "AWS::SageMaker::NotebookInstance"
Properties:
  KmsKeyId: String
  DirectInternetAccess: String
  SubnetId: String
  NotebookInstanceName: String
  InstanceType: String
  LifecycleConfigName: String
  SecurityGroupIds:
    - String
  RoleArn: String
  Tags:
    - Tag (p. 2258)
```

Properties

`KmsKeyId`

If you provide a AWS KMS key ID, Amazon SageMaker uses it to encrypt data at rest on the ML storage volume that is attached to your notebook instance.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DirectInternetAccess`

Sets whether Amazon SageMaker provides internet access to the notebook instance. If you set this to Disabled this notebook instance will be able to access resources only in your VPC, and will not be able to connect to Amazon SageMaker training and endpoint services unless your configure a NAT Gateway in your VPC. For more information, see Notebook Instances Are Enabled with Internet Access by Default. You can set the value of this parameter to Disabled only if you set a value for the SubnetId parameter.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SubnetId`

The ID of the subnet in a VPC to which you would like to have a connectivity from your ML compute instance.

Required: No

Type: String

Update requires: Replacement (p. 121)

`NotebookInstanceName`

The name of the notebook instance.

Required: No

Type: String

Update requires: Replacement (p. 121)

`InstanceType`

The type of ML compute instance to launch for the notebook instance.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`LifecycleConfigName`

The name of a lifecycle configuration to associate with the notebook instance. For information about lifestyle configurations, see Customize a Notebook Instance in the *Amazon SageMaker Developer Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`SecurityGroupIds`

The VPC security group IDs, in the form sg-xxxxxxxx. The security groups must be for the same VPC as specified in the subnet.

Required: No

Type: List of Strings

Update requires: Replacement (p. 121)

`RoleArn`

When you send any requests to AWS resources from the notebook instance, Amazon SageMaker assumes this role to perform tasks on your behalf. You must grant this role necessary permissions so Amazon SageMaker can perform these tasks. The policy must allow the Amazon SageMaker service principal (sagemaker.amazonaws.com) permissions to assume this role. For more information, see Amazon SageMaker Roles.

Required: Yes

Type:

Update requires: No interruption (p. 120)

`Tags`

A list of tags to associate with the notebook instance.

Required: No

Type: List of Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::SageMaker::NotebookInstance` resource to the intrinsic `Ref` function, the function returns the Amazon Resource Name (ARN) of the notebook instance, such as `arn:aws:sagemaker:us-west-2:012345678901:notebook-instance/mynotebookinstance`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`NotebookInstanceName`

The name of the notebook instance, such as `MyNotebookInstance`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

SageMaker Notebook Instance Example

The following example creates a notebook instance.

JSON

```
{
  "Description": "Basic NotebookInstance test update to a different instance type",
  "Resources": {
    "BasicNotebookInstance": {
      "Type": "AWS::SageMaker::NotebookInstance",
      "Properties": {
        "InstanceType": "ml.t2.large",
        "RoleArn": { "Fn::GetAtt" : [ "ExecutionRole", "Arn" ] }
      }
    },
    "ExecutionRole": {
      "Type": "AWS::IAM::Role",
      "Properties": {
        "AssumeRolePolicyDocument": {
          "Version": "2012-10-17",
```

```
          "Statement": [
            {
              "Effect": "Allow",
              "Principal": {
                "Service": [
                  "sagemaker.amazonaws.com"
                ]
              },
              "Action": [
                "sts:AssumeRole"
              ]
            }
          ]
        },
        "Path": "/",
        "Policies": [
          {
            "PolicyName": "root",
            "PolicyDocument": {
              "Version": "2012-10-17",
              "Statement": [
                {
                  "Effect": "Allow",
                  "Action": "*",
                  "Resource": "*"
                }
              ]
            }
          }
        ]
      }
    }
  },
  "Outputs": {
    "BasicNotebookInstanceId": {
       "Value": { "Ref" : "BasicNotebookInstance" }
       }
  },

}
```

YAML

```
Description: "Basic NotebookInstance test update to a different instance type"
Resources:
  BasicNotebookInstance:
    Type: "AWS::SageMaker::NotebookInstance"
    Properties:
      InstanceType: "ml.t2.large"
      RoleArn: !GetAtt ExecutionRole.Arn
  ExecutionRole:
    Type: "AWS::IAM::Role"
    Properties:
      AssumeRolePolicyDocument:
        Version: "2012-10-17"
        Statement:
          -
            Effect: "Allow"
            Principal:
              Service:
                - "sagemaker.amazonaws.com"
            Action:
              - "sts:AssumeRole"
```

```
      Path: "/"
      Policies:
        -
          PolicyName: "root"
          PolicyDocument:
            Version: "2012-10-17"
            Statement:
              -
                Effect: "Allow"
                Action: "*"
                Resource: "*"
Outputs:
  BasicNotebookInstanceId:
    Value: !Ref BasicNotebookInstance
```

AWS::SageMaker::NotebookInstanceLifecycleConfig

The `AWS::SageMaker::NotebookInstanceLifecycleConfig` resource specifies shell scripts that run when you create and/or start a notebook instance. For more information, see Customize a Notebook Instance in the *Amazon SageMaker Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SageMaker::NotebookInstanceLifecycleConfig",
  "Properties" : {
    "OnStart" : [ NotebookInstanceLifecycleHook (p. 2065), ... ],
    "NotebookInstanceLifecycleConfigName" : String,
    "OnCreate" : [ NotebookInstanceLifecycleHook (p. 2065), ... ]
  }
}
```

YAML

```
Type: "AWS::SageMaker::NotebookInstanceLifecycleConfig"
Properties:
  OnStart:
    - NotebookInstanceLifecycleHook (p. 2065)
  NotebookInstanceLifecycleConfigName: String
  OnCreate:
    - NotebookInstanceLifecycleHook (p. 2065)
```

Properties

`OnStart`

A shell script that runs once when you create a notebook instance, and then each time you start the notebook instance.

Required: No

Type: List of Amazon SageMaker NotebookInstanceLifecycleConfig NotebookInstanceLifecycleHook (p. 2065)

Update requires: No interruption (p. 120)

`NotebookInstanceLifecycleConfigName`

The name of the lifecycle configuration.

Required: No

Type: String

Update requires: Replacement (p. 121)

`OnCreate`

A shell script that runs only once, when you create a notebook instance.

Required: No

Type: List of Amazon SageMaker NotebookInstanceLifecycleConfig NotebookInstanceLifecycleHook (p. 2065)

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::SageMaker::NotebookInstanceLifecycleConfig` resource to the intrinsic `Ref` function, the function returns the Amazon Resource Name (ARN) of the lifecycle configuration, such as `arn:aws:sagemaker:us-west-2:012345678901:notebook-instance-lifecycle-config/mylifecycleconfig`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`NotebookInstanceLifecycleConfigName`

The name of the lifecycle configuration, such as `MyLifecycleConfig`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

Notebook Instance Lifecycle Config Example

The following example creates a notebook instance with an associated lifecycle configuration.

JSON

```
{
  "Description": "Basic NotebookInstance test",
  "Resources": {
    "BasicNotebookInstance": {
      "Type": "AWS::SageMaker::NotebookInstance",
      "Properties": {
        "InstanceType": "ml.t2.medium",
        "RoleArn": { "Fn::GetAtt" : [ "ExecutionRole", "Arn" ] },
        "LifecycleConfigName": { "Fn::GetAtt" : [ "BasicNotebookInstanceLifecycleConfig",
 "NotebookInstanceLifecycleConfigName" ] }
```

```
    },
    "BasicNotebookInstanceLifecycleConfig": {
      "Type": "AWS::SageMaker::NotebookInstanceLifecycleConfig",
      "Properties": {
        "OnStart": [
          {
            "Content": {
              "Fn::Base64": "echo 'hello'"
            }
          }
        ]
      }
    },
    "ExecutionRole": {
      "Type": "AWS::IAM::Role",
      "Properties": {
        "AssumeRolePolicyDocument": {
          "Version": "2012-10-17",
          "Statement": [
            {
              "Effect": "Allow",
              "Principal": {
                "Service": [
                  "sagemaker.amazonaws.com"
                ]
              },
              "Action": [
                "sts:AssumeRole"
              ]
            }
          ]
        },
        "Path": "/",
        "Policies": [
          {
            "PolicyName": "root",
            "PolicyDocument": {
              "Version": "2012-10-17",
              "Statement": [
                {
                  "Effect": "Allow",
                  "Action": "*",
                  "Resource": "*"
                }
              ]
            }
          }
        ]
      }
    }
  },
  "Outputs": {
    "BasicNotebookInstanceId": {
      "Value": { "Ref" : "BasicNotebookInstance" }
    },
    "BasicNotebookInstanceLifecycleConfigId": {
      "Value": { "Ref" : "BasicNotebookInstanceLifecycleConfig" }
    }
  },
}
```

YAML

```
Description: "Basic NotebookInstance test"
Resources:
  BasicNotebookInstance:
    Type: "AWS::SageMaker::NotebookInstance"
    Properties:
      InstanceType: "ml.t2.medium"
      RoleArn: !GetAtt ExecutionRole.Arn
      LifecycleConfigName: !GetAtt
 BasicNotebookInstanceLifecycleConfig.NotebookInstanceLifecycleConfigName
  BasicNotebookInstanceLifecycleConfig:
    Type: "AWS::SageMaker::NotebookInstanceLifecycleConfig"
    Properties:
      OnStart:

                Effect: "Allow"
                Action: "*"
                Resource: "*"
Outputs:
  BasicNotebookInstanceId:
    Value: !Ref BasicNotebookInstance
  BasicNotebookInstanceLifecycleConfigId:
    Value: !Ref BasicNotebookInstanceLifecycleConfig
```

Amazon SageMaker NotebookInstanceLifecycleConfig NotebookInstanceLifecycleHook

The `NotebookInstanceLifecycleHook` property type specifies the notebook instance lifecycle configuration script.

`NotebookInstanceLifecycleHook` is a property of the AWS::SageMaker::NotebookInstanceLifecycleConfig (p. 2062) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Content" : String
```

```
}
```

YAML

```
Content: String
```

Properties

`Content`

A base64-encoded string that contains a shell script for a notebook instance lifecycle configuration.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Service Catalog Resource Types Reference

This section contains reference information for all AWS Service Catalog resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::ServiceCatalog::data-type-name
```

Topics

- AWS::ServiceCatalog::AcceptedPortfolioShare (p. 2066)
- AWS::ServiceCatalog::CloudFormationProduct (p. 2067)
- AWS::ServiceCatalog::CloudFormationProvisionedProduct (p. 2071)
- AWS::ServiceCatalog::LaunchNotificationConstraint (p. 2075)
- AWS::ServiceCatalog::LaunchRoleConstraint (p. 2077)
- AWS::ServiceCatalog::LaunchTemplateConstraint (p. 2078)
- AWS::ServiceCatalog::Portfolio (p. 2080)
- AWS::ServiceCatalog::PortfolioPrincipalAssociation (p. 2082)
- AWS::ServiceCatalog::PortfolioProductAssociation (p. 2083)
- AWS::ServiceCatalog::PortfolioShare (p. 2084)
- AWS::ServiceCatalog::TagOption (p. 2086)
- AWS::ServiceCatalog::TagOptionAssociation (p. 2087)

AWS::ServiceCatalog::AcceptedPortfolioShare

Accepts an offer to share the specified portfolio for AWS Service Catalog. For more information, see AcceptPortfolioShare in the *AWS Service Catalog Developer Guide*.

Topics

- Syntax (p. 2067)
- Properties (p. 2067)

- Return Values (p. 2067)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::AcceptedPortfolioShare",
  "Properties" : {
    "AcceptLanguage" : String,
    "PortfolioId" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::AcceptedPortfolioShare"
Properties:
  AcceptLanguage: String
  PortfolioId: String
```

Properties

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PortfolioId`

The portfolio identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::AcceptedPortfolioShare` resource to the intrinsic `Ref` function, the function returns a unique identifier.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::ServiceCatalog::CloudFormationProduct

Creates the specified product for AWS Service Catalog. For more information, see CreateProduct in the *AWS Service Catalog Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::CloudFormationProduct",
  "Properties" : {
    "Owner" : String,
    "SupportDescription" : String,
    "Description" : String,
    "Distributor" : String,
    "SupportEmail" : String,
    "AcceptLanguage" : String,
    "SupportUrl" : String,
    "Tags" : [ Resource Tag (p. 2258), ... ],
    "Name" : String,
    "ProvisioningArtifactParameters" : [ ProvisioningArtifactProperties (p. 2070), ... ]
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::CloudFormationProduct"
Properties:
  Owner: String
  SupportDescription: String
  Description: String
  Distributor: String
  SupportEmail: String
  AcceptLanguage: String
  SupportUrl: String
  Tags:
    - Resource Tag (p. 2258)
  Name: String
  ProvisioningArtifactParameters:
    - ProvisioningArtifactProperties (p. 2070)
```

Properties

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the product.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Distributor`

The distributor of the product.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the product.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Owner`

The owner of the product.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ProvisioningArtifactParameters`

The configuration of the provisioning artifact (also known as a version) for a product.

Required: Yes

Type: List of ProvisioningArtifactProperties (p. 2070) property types

Update requires: No interruption (p. 120)

`SupportDescription`

The support information about the product.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SupportEmail`

The contact email for product support.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SupportUrl`

The contact URL for product support.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Tags`

One or more tags.

Required: No

Type: List of `Resource Tag` (p. 2258) property types

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::CloudFormationProduct` resource to the intrinsic `Ref` function, the function returns the ID of the provisioning artifact, such as `prod-nd24wbqkm4pju`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes.

`ProductName`

The name of the product.

`ProvisioningArtifactIds`

The IDs of the provisioning artifacts.

`ProvisioningArtifactNames`

The names of the provisioning artifacts.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

AWS Service Catalog CloudFormationProduct ProvisioningArtifactProperties

The `ProvisioningArtifactProperties` property type specifies information about a provisioning artifact (also known as a version) for a product.

`ProvisioningArtifactProperties` is a property of the AWS::ServiceCatalog::CloudFormationProduct (p. 2067) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Description" : String,
  "Info" : Json,
  "Name" : String
```

```
}
```

YAML

```
Description: String
Info: Json
Name: String
```

Properties

`Description`

The description of the provisioning artifact.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Info`

The URL of the CloudFormation template in Amazon S3. Specify the URL in JSON format as follows:

`"LoadTemplateFromURL": "https://s3.amazonaws.com/cf-templates-ozkq9d3hgiq2-us-east-1/..."`

Required: Yes

Type: Json

Update requires: No interruption (p. 120)

`Name`

The name of the provisioning artifact.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS::ServiceCatalog::CloudFormationProvisionedProduct

Provisions the specified product for AWS Service Catalog. For more information, see ProvisionProduct in the *AWS Service Catalog Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::CloudFormationProvisionedProduct",
  "Properties" : {
    "PathId" : String,
    "ProvisioningParameters" : [ ProvisioningParameter (p. 2074), ... ],
    "ProductName" : String,
```

```
    "ProvisioningArtifactName" : String,
    "NotificationArns" : [ String, ... ],
    "AcceptLanguage" : String,
    "ProductId" : String,
    "Tags" : [ Tag (p. 2258), ... ],
    "ProvisionedProductName" : String,
    "ProvisioningArtifactId" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::CloudFormationProvisionedProduct"
Properties:
  PathId: String
  ProvisioningParameters:
    - ProvisioningParameter (p. 2074)
  ProductName: String
  ProvisioningArtifactName: String
  NotificationArns:
    - String
  AcceptLanguage: String
  ProductId: String
  Tags:
    - Tag (p. 2258)
  ProvisionedProductName: String
  ProvisioningArtifactId: String
```

Properties

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: No interruption (p. 120)

`NotificationArns`

The SNS topic ARNs for stack-related events.

Required: No

Type: List of String values

Update requires: Replacement (p. 121)

`PathId`

The path identifier of the product.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ProductId`

The product identifier. You must specify either the ID or the name of the product, but not both.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ProductName`

The product name. This name must be unique for the user. You must specify either the name or the ID of the product, but not both.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ProvisionedProductName`

A user-friendly name for the provisioned product. This name must be unique for the AWS account and cannot be updated after the product is provisioned.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ProvisioningArtifactId`

The identifier of the provisioning artifact (also known as a version) for the product. You must specify either the ID or the name of the provisioning artifact, but not both.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ProvisioningArtifactName`

The name of the provisioning artifact (also known as a version) for the product. This name must be unique for the product. You must specify either the name or the ID of the provisioning artifact, but not both.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ProvisioningParameters`

Parameters specified by the administrator that are required for provisioning the product.

Required: No

Type: List of ProvisioningParameter (p. 2074) property types

Update requires: No interruption (p. 120)

`Tags`

One or more tags.

Required: No

Type: List of Resource Tag (p. 2258) property types

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::CloudFormationProvisionedProduct` resource to the intrinsic `Ref` function, the function returns the provisioned product ID, such as `pp-hfyszaotincww`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`CloudformationStackArn`

The Amazon Resource Name (ARN) of the CloudFormation stack, such as `arn:aws:cloudformation:eu-west-1:123456789012:stack/SC-499278721343-pp-hfyszaotincww/8f3df460-346a-11e8-9444-503abe701c29`.

`RecordId`

The ID of the record, such as `rec-rjeatvy434trk`.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

AWS Service Catalog CloudFormationProvisionedProduct ProvisioningParameter

The `ProvisioningParameter` property type specifies a parameter for an AWS Service Catalog provisioned product.

`ProvisioningParameter` is a property of the AWS::ServiceCatalog::CloudFormationProvisionedProduct (p. 2071) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Value" : String,
  "Key" : String
}
```

YAML

```
Value: String
Key: String
```

Properties

`Key`

The parameter key.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Value`

The parameter value.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS::ServiceCatalog::LaunchNotificationConstraint

Creates a notification constraint for AWS Service Catalog. For more information, see CreateConstraint in the *AWS Service Catalog Developer Guide*.

Topics

- Syntax (p. 2075)
- Properties (p. 2076)
- Return Values (p. 2076)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::LaunchNotificationConstraint",
  "Properties" : {
    "Description" : String,
    "NotificationArns" : [ String, ... ],
    "AcceptLanguage" : String,
    "PortfolioId" : String,
    "ProductId" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::LaunchNotificationConstraint"
Properties:
  Description: String
  NotificationArns:
    - String
  AcceptLanguage: String
  PortfolioId: String
```

```
  ProductId: String
```

Properties

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the constraint.

Required: No

Type: String

Update requires: No interruption (p. 120)

`NotificationArns`

The notification ARNs.

Required: Yes

Type: List of String values

Update requires: Replacement (p. 121)

`PortfolioId`

The portfolio identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ProductId`

The product identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::LaunchNotificationConstraint` resource to the intrinsic `Ref` function, the function returns the identifier of the constraint.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::ServiceCatalog::LaunchRoleConstraint

Creates a launch constraint for AWS Service Catalog. For more information, see CreateConstraint in the *AWS Service Catalog Developer Guide*.

Topics

- Syntax (p. 2077)
- Properties (p. 2077)
- Return Values (p. 2078)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::LaunchRoleConstraint",
  "Properties" : {
    "Description" : String,
    "AcceptLanguage" : String,
    "PortfolioId" : String,
    "ProductId" : String,
    "RoleArn" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::LaunchRoleConstraint"
Properties:
  Description: String
  AcceptLanguage: String
  PortfolioId: String
  ProductId: String
  RoleArn: String
```

Properties

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the constraint.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PortfolioId`

The portfolio identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ProductId`

The product identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`RoleArn`

The ARN of the launch role.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::LaunchRoleConstraint` resource to the intrinsic `Ref` function, the function returns the identifier of the constraint.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::ServiceCatalog::LaunchTemplateConstraint

Creates a template constraint for AWS Service Catalog. For more information, see CreateConstraint in the *AWS Service Catalog Developer Guide*.

Topics

- Syntax (p. 2078)
- Properties (p. 2079)
- Return Values (p. 2080)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::LaunchTemplateConstraint",
  "Properties" : {
    "Description" : String,
```

```
    "AcceptLanguage" : String,
    "PortfolioId" : String,
    "ProductId" : String,
    "Rules" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::LaunchTemplateConstraint"
Properties:
  Description: String
  AcceptLanguage: String
  PortfolioId: String
  ProductId: String
  Rules: String
```

Properties

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the constraint.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PortfolioId`

The portfolio identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ProductId`

The product identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Rules`

The constraint rules.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::LaunchTemplateConstraint` resource to the intrinsic `Ref` function, the function returns the identifier of the constraint.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::ServiceCatalog::Portfolio

Creates a portfolio for AWS Service Catalog. For more information, see CreatePortfolio in the *AWS Service Catalog Developer Guide*.

Topics

- Syntax (p. 2080)
- Properties (p. 2080)
- Return Values (p. 2081)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::Portfolio",
  "Properties" : {
    "ProviderName" : String,
    "Description" : String,
    "DisplayName" : String,
    "AcceptLanguage" : String,
    "Tags" : [ Resource Tag (p. 2258), ... ]
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::Portfolio"
Properties:
  ProviderName: String
  Description: String
  DisplayName: String
  AcceptLanguage: String
  Tags:
    - Resource Tag (p. 2258)
```

Properties

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

The description of the portfolio.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DisplayName`

The name to use for display purposes.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`ProviderName`

The name of the portfolio provider.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Tags`

One or more tags.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::Portfolio` resource to the intrinsic `Ref` function, the function returns the portfolio identifier.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`PortfolioName`

The name of the portfolio.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

AWS::ServiceCatalog::PortfolioPrincipalAssociation

Associates the specified principal with the specified portfolio for AWS Service Catalog. For more information, see AssociatePrincipalWithPortfolio in the *AWS Service Catalog Developer Guide*.

Topics

- Syntax (p. 2082)
- Properties (p. 2082)
- Return Values (p. 2083)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::PortfolioPrincipalAssociation",
  "Properties" : {
    "PrincipalARN" : String,
    "AcceptLanguage" : String,
    "PortfolioId" : String,
    "PrincipalType" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::PortfolioPrincipalAssociation"
Properties:
  PrincipalARN: String
  AcceptLanguage: String
  PortfolioId: String
  PrincipalType: String
```

Properties

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PortfolioId`

The portfolio identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`PrincipalARN`

The ARN of the principal (IAM user, role, or group).

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`PrincipalType`

The principal type (`IAM`).

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::PortfolioPrincipalAssociation` resource to the intrinsic `Ref` function, the function returns a unique identifier for the association.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::ServiceCatalog::PortfolioProductAssociation

Associates the specified product with the specified portfolio for AWS Service Catalog. For more information, see AssociateProductWithPortfolio in the *AWS Service Catalog Developer Guide*.

Topics

- Syntax (p. 2083)
- Properties (p. 2084)
- Return Values (p. 2084)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::PortfolioProductAssociation",
  "Properties" : {
    "SourcePortfolioId" : String,
    "AcceptLanguage" : String,
    "PortfolioId" : String,
    "ProductId" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::PortfolioProductAssociation"
```

```
Properties:
  SourcePortfolioId: String
  AcceptLanguage: String
  PortfolioId: String
  ProductId: String
```

Properties

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PortfolioId`

The portfolio identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ProductId`

The product identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SourcePortfolioId`

The identifier of the source portfolio.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::PortfolioProductAssociation` resource to the intrinsic `Ref` function, the function returns a unique identifier for the association.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::ServiceCatalog::PortfolioShare

Shares the specified portfolio for AWS Service Catalog with the specified account. For more information, see CreatePortfolioShare in the *AWS Service Catalog Developer Guide*.

Topics

- Syntax (p. 2085)
- Properties (p. 2085)
- Return Values (p. 2086)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::PortfolioShare",
  "Properties" : {
    "AccountId" : String,
    "AcceptLanguage" : String,
    "PortfolioId" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::PortfolioShare"
Properties:
  AccountId: String
  AcceptLanguage: String
  PortfolioId: String
```

Properties

`AccountId`

The AWS account ID.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`AcceptLanguage`

The language code.

Required: No

Type: String

Update requires: Replacement (p. 121)

`PortfolioId`

The portfolio identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::PortfolioShare` resource to the intrinsic `Ref` function, the function returns the identifier of the portfolio share.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::ServiceCatalog::TagOption

A TagOption is a key-value pair managed by AWS Service Catalog that serves as a template for creating an AWS tag. For more information, see AWS Service Catalog TagOptionLibrary in the *AWS Service Catalog Administrator Guide*.

Topics

- Syntax (p. 2086)
- Properties (p. 2086)
- Return Values (p. 2087)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::TagOption",
  "Properties" : {
    "Active" : Boolean,
    "Value" : String,
    "Key" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::TagOption"
Properties:
  Active: Boolean
  Value: String
  Key: String
```

Properties

`Active`

Indicates whether the TagOption is active.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Key`

The TagOption key.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Value`

The TagOption value.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::TagOption` resource to the intrinsic `Ref` function, the function returns the TagOption identifier.

For more information about using the `Ref` function, see Ref (p. 2341).

AWS::ServiceCatalog::TagOptionAssociation

Associates the specified TagOption with the specified AWS Service Catalog resource. For more information, see AWS Service Catalog TagOptionLibrary in the *AWS Service Catalog Administrator Guide*.

Topics

- Syntax (p. 2087)
- Properties (p. 2088)
- Return Values (p. 2088)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::ServiceCatalog::TagOptionAssociation",
  "Properties" : {
    "TagOptionId" : String,
    "ResourceId" : String
  }
}
```

YAML

```
Type: "AWS::ServiceCatalog::TagOptionAssociation"
Properties:
  TagOptionId: String
  ResourceId: String
```

Properties

`ResourceId`

The resource identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`TagOptionId`

The TagOption identifier.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::ServiceCatalog::TagOptionAssociation` resource to the intrinsic `Ref` function, the function returns an identifier for the association.

For more information about using the `Ref` function, see Ref (p. 2341).

Amazon Simple Email Service Resource Types Reference

This section contains reference information for all Amazon Simple Email Service resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::SES::data-type-name
```

Topics

- AWS::SES::ConfigurationSet (p. 2088)
- AWS::SES::ConfigurationSetEventDestination (p. 2090)
- AWS::SES::ReceiptFilter (p. 2098)
- AWS::SES::ReceiptRule (p. 2102)
- AWS::SES::ReceiptRuleSet (p. 2118)
- AWS::SES::Template (p. 2120)

AWS::SES::ConfigurationSet

The `AWS::SES::ConfigurationSet` resource lets you create groups of rules that you can apply to the emails you send using Amazon SES. For more information about using configuration sets, see Using Amazon SES Configuration Sets in the *Amazon Simple Email Service Developer Guide*.

Configuration sets

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SES::ConfigurationSet",
  "Properties" : {
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::SES::ConfigurationSet"
Properties:
  Name: String
```

Properties

`Name`

The name of the configuration set. The name must meet the following requirements:

- Contain only letters (a-z, A-Z), numbers (0-9), underscores (_), or dashes (-).
- Contain 64 characters or fewer.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "AWS SES ConfigurationSet Sample Template",
    "Parameters": {
        "ConfigSetName": {
            "Type": "String"
        }
    },
```

```
    "Resources": {
        "ConfigSet": {
            "Type": "AWS::SES::ConfigurationSet",
            "Properties": {
                "Name": {
                    "Ref": "ConfigSetName"
                }
            }
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Description: "AWS SES ConfigurationSet Sample Template"
Parameters:
  ConfigSetName:
    Type: String
Resources:
  ConfigSet:
    Type: AWS::SES::ConfigurationSet
    Properties:
      Name: !Ref ConfigSetName
```

See Also

- Using Amazon SES Configuration Sets in the *Amazon Simple Email Service Developer Guide*
- ConfigurationSet in the *Amazon Simple Email Service API Reference*

AWS::SES::ConfigurationSetEventDestination

The `AWS::SES::ConfigurationSetEventDestination` resource specifies a configuration set event destination for Amazon SES. For more information, see CreateConfigurationSetEventDestination in the *Amazon Simple Email Service API Reference*.

> **Note**
> When you create or update an event destination, you must provide one, and only one, destination. The destination can be Amazon CloudWatch or Amazon Kinesis Data Firehose.

An event destination is the AWS service to which Amazon SES publishes the email sending events associated with a configuration set. For information, see Using Amazon SES Configuration Sets in the *Amazon Simple Email Service Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SES::ConfigurationSetEventDestination",
  "Properties" : {
    "ConfigurationSetName" : String,
    "EventDestination" : EventDestination (p. 2096)
  }
}
```

YAML

```
Type: "AWS::SES::ConfigurationSetEventDestination"
Properties:
  ConfigurationSetName: String
  EventDestination: EventDestination (p. 2096)
```

Properties

`ConfigurationSetName`

The name of the configuration set that the event destination should be associated with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`EventDestination`

The AWS service that email sending event information will be published to.

Required: Yes

Type: EventDestination (p. 2096)

Update requires: No interruption (p. 120)

Example

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "AWS SES ConfigurationSetEventDestination Sample Template",
    "Parameters": {
        "ConfigSetName": {
            "Type": "String"
        },
        "EventDestinationName": {
            "Type": "String"
        },
        "EventType1": {
            "Type": "String"
        },
        "EventType2": {
            "Type": "String"
        },
        "EventType3": {
            "Type": "String"
        },
        "DimensionName1": {
            "Type": "String"
        },
        "DimensionValueSource1": {
            "Type": "String"
        },
        "DefaultDimensionValue1": {
            "Type": "String"
        },
        "DimensionName2": {
            "Type": "String"
```

```
        },
        "DimensionValueSource2": {
            "Type": "String"
        },
        "DefaultDimensionValue2": {
            "Type": "String"
        }
    },
    "Resources": {
        "ConfigSet": {
            "Type": "AWS::SES::ConfigurationSet",
            "Properties": {
                "Name": {
                    "Ref": "ConfigSetName"
                }
            }
        },
        "CWEventDestination": {
            "Type": "AWS::SES::ConfigurationSetEventDestination",
            "Properties": {
                "ConfigurationSetName": {
                    "Ref": "ConfigSet"
                },
                "EventDestination": {
                    "Name": {
                        "Ref": "EventDestinationName"
                    },
                    "Enabled": true,
                    "MatchingEventTypes": [
                        {
                            "Ref": "EventType1"
                        },
                        {
                            "Ref": "EventType2"
                        },
                        {
                            "Ref": "EventType3"
                        }
                    ],
                    "CloudWatchDestination": {
                        "DimensionConfigurations": [
                            {
                                "DimensionName": {
                                    "Ref": "DimensionName1"
                                },
                                "DimensionValueSource": {
                                    "Ref": "DimensionValueSource1"
                                },
                                "DefaultDimensionValue": {
                                    "Ref": "DefaultDimensionValue1"
                                }
                            },
                            {
                                "DimensionName": {
                                    "Ref": "DimensionName2"
                                },
                                "DimensionValueSource": {
                                    "Ref": "DimensionValueSource2"
                                },
                                "DefaultDimensionValue": {
                                    "Ref": "DefaultDimensionValue2"
                                }
                            }
                        ]
                    }
                }
```

```
            }
        }
    }
}
```

Amazon Simple Email Service ConfigurationSetEventDestination CloudWatchDestination

The `CloudWatchDestination` property type specifies information associated with an CloudWatch event destination to which email sending events are published in Amazon SES.

`CloudWatchDestination` is a property of the EventDestination (p. 2096) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "DimensionConfigurations" : [ DimensionConfiguration (p. 2094), ... ]
}
```

YAML

```
DimensionConfigurations:
  - DimensionConfiguration (p. 2094)
```

Properties

`DimensionConfigurations`

A list of dimensions upon which to categorize your emails when you publish email sending events to CloudWatch.

Required: No

Type: List of DimensionConfiguration (p. 2094)

Update requires: No interruption (p. 120)

See Also

- Using Amazon SES Configuration Sets in the *Amazon Simple Email Service Developer Guide*
- CloudWatchDestination in the *Amazon Simple Email Service API Reference*

Amazon Simple Email Service ConfigurationSetEventDestination DimensionConfiguration

The `DimensionConfiguration` property type specifies the dimension configuration to use when you publish email sending events to Amazon CloudWatch using Amazon SES.

`DimensionConfiguration` is a property of the CloudWatchDestination (p. 2094) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "DimensionValueSource" : String,
  "DefaultDimensionValue" : String,
  "DimensionName" : String
}
```

YAML

```
DimensionValueSource: String
DefaultDimensionValue: String
DimensionName: String
```

Properties

`DefaultDimensionValue`

The default value of the dimension that is published to Amazon CloudWatch if you do not provide the value of the dimension when you send an email. The default value can:

- Contain ASCII letters (a-z, A-Z), numbers (0-9), underscores (_), or dashes (-).
- Contain up to 256 characters.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`DimensionName`

The name of an Amazon CloudWatch dimension associated with an email sending metric. The name can:

- Contain ASCII letters (a-z, A-Z), numbers (0-9), underscores (_), or dashes (-).
- Contain up to 256 characters.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`DimensionValueSource`

The place where Amazon SES finds the value of a dimension to publish to CloudWatch. If you want Amazon SES to use the message tags that you specify using an `X-SES-MESSAGE-TAGS` header or a parameter to the `SendEmail/SendRawEmail`API, choose `messageTag`. If you want Amazon SES to use your own email headers, choose `emailHeader`.

Valid values include: `emailHeader`, `linkTag`, and `messageTag`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

See Also

- Using Amazon SES Configuration Sets in the *Amazon Simple Email Service Developer Guide*
- CloudWatchDimensionConfiguration in the *Amazon Simple Email Service API Reference*

Amazon Simple Email Service ConfigurationSetEventDestination EventDestination

For an Amazon SES configuration set event destination, the `EventDestination` property type specifies information about the event destination that the specified email sending events will be published to.

> **Note**
> When you create or update an event destination, you must provide one, and only one, destination. The destination can be Amazon CloudWatch or Amazon Kinesis Data Firehose.

Event destinations are associated with configuration sets, which enable you to publish email sending events to Amazon CloudWatch or Amazon Kinesis Data Firehose. For information, see Using Amazon SES Configuration Sets in the *Amazon Simple Email Service Developer Guide*.

`EventDestination` is a property of the AWS::SES::ConfigurationSetEventDestination (p. 2090) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "CloudWatchDestination" : CloudWatchDestination (p. 2094),
  "Enabled" : Boolean,
  "MatchingEventTypes" : [ String, ... ],
  "Name" : String,
  "KinesisFirehoseDestination" : KinesisFirehoseDestination (p. 2097)
}
```

YAML

```
CloudWatchDestination: CloudWatchDestination (p. 2094)
Enabled: Boolean
MatchingEventTypes:
  - String
Name: String
KinesisFirehoseDestination: KinesisFirehoseDestination (p. 2097)
```

Properties

`CloudWatchDestination`

The names, default values, and sources of the dimensions associated with an CloudWatch event destination.

Required: No

Type: CloudWatchDestination (p. 2094)

Update requires: No interruption (p. 120)

`Enabled`

Sets whether Amazon SES publishes events to this destination when you send an email with the associated configuration set. Set to `true` to enable publishing to this destination; set to `false` to prevent publishing to this destination. The default value is `false`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`KinesisFirehoseDestination`

Contains the delivery stream ARN and the IAM role ARN associated with an Kinesis Data Firehose event destination.

Required: No

Type: KinesisFirehoseDestination (p. 2097)

Update requires: No interruption (p. 120)

`MatchingEventTypes`

The type of email sending events to publish to the event destination.

For a list of valid values, see EventDestination in the *Amazon Simple Email Service API Reference*.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

`Name`

The name of the event destination. The name can:

- Contain ASCII letters (a-z, A-Z), numbers (0-9), underscores (_), or dashes (-).
- Contain up to 64 characters.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- Using Amazon SES Configuration Sets in the *Amazon Simple Email Service Developer Guide*
- EventDestination in the *Amazon Simple Email Service API Reference*

Amazon Simple Email Service ConfigurationSetEventDestination KinesisFirehoseDestination

The `KinesisFirehoseDestination` property type specifies the delivery stream ARN and the IAM role ARN associated with an Kinesis Data Firehose event destination for an Amazon SES configuration set.

`KinesisFirehoseDestination` is a property of the EventDestination (p. 2096) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "IAMRoleARN" : String,
  "DeliveryStreamARN" : String
}
```

YAML

```
IAMRoleARN: String
DeliveryStreamARN: String
```

Properties

`IAMRoleARN`

The ARN of the IAM role under which Amazon SES publishes email sending events to the Amazon Kinesis Data Firehose stream.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`DeliveryStreamARN`

The ARN of the Amazon Kinesis Data Firehose stream that email sending events should be published to.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

AWS::SES::ReceiptFilter

The `AWS::SES::ReceiptFilter` resource whether to accept or reject mail originating from an IP address or range of IP addresses for Amazon SES. For more information, see Creating IP Address Filters for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SES::ReceiptFilter",
  "Properties" : {
    "Filter" : Filter (p. 2100)
  }
}
```

YAML

```
Type: "AWS::SES::ReceiptFilter"
Properties:
  Filter: Filter (p. 2100)
```

Properties

`Filter`

The IP addresses to block or allow, and whether to block or allow incoming mail from them.

Required: Yes

Type: Filter (p. 2100)

Update requires: Replacement (p. 121)

Example

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "AWS SES ReceiptFilter Sample Template",
    "Parameters": {
        "FilterName": {
            "Type": "String"
        },
        "Policy": {
            "Type": "String"
        },
        "Cidr": {
            "Type": "String"
        }
    },
    "Resources": {
        "ReceiptFilter": {
            "Type": "AWS::SES::ReceiptFilter",
            "Properties": {
                "Filter": {
                    "Name": {
                        "Ref": "FilterName"
                    },
                    "IpFilter": {
                        "Policy": {
                            "Ref": "Policy"
                        },
                        "Cidr": {
                            "Ref": "Cidr"
                        }
                    }
                }
            }
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
```

```
Description: 'AWS SES ReceiptFilter Sample Template'
Parameters:
  FilterName:
    Type: String
  Policy:
    Type: String
  Cidr:
    Type: String
Resources:
  ReceiptFilter:
    Type: AWS::SES::ReceiptFilter
    Properties:
      Filter:
        Name: !Ref FilterName
        IpFilter:
          Policy: !Ref Policy
          Cidr: !Ref Cidr
```

Amazon Simple Email Service ReceiptFilter Filter

The `Filter` property type specifies specify whether to accept or reject mail originating from an IP address or range of IP addresses for Amazon SES.

`Filter` is a property of the AWS::SES::ReceiptFilter (p. 2098) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "IpFilter" : IpFilter (p. 2101),
  "Name" : String
}
```

YAML

```
IpFilter: IpFilter (p. 2101)
Name: String
```

Properties

`IpFilter`

The IP addresses to block or allow, and whether to block or allow incoming mail from them.

Required: Yes

Type: IpFilter (p. 2101)

Update requires: No interruption (p. 120)

`Name`

The name of the IP address filter. The name must:

- Contain only ASCII letters (a-z, A-Z), numbers (0-9), underscores (_), or dashes (-).
- Start and end with a letter or number.
- Contain less than 64 characters.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- Creating IP Address Filters for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*
- ReceiptFilter in the *Amazon Simple Email Service API Reference*

Amazon Simple Email Service ReceiptFilter IpFilter

The `IpFilter` property type specifies whether to accept or reject mail originating from an IP address or range of IP addresses for Amazon SES.

`IpFilter` is a property of the Amazon Simple Email Service ReceiptFilter Filter (p. 2100) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Policy" : String,
  "Cidr" : String
}
```

YAML

```
Policy: String
Cidr: String
```

Properties

`Policy`

Indicates whether to block or allow incoming mail from the specified IP addresses.

Valid values include `Allow` and `Block`

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Cidr`

A single IP address or a range of IP addresses that you want to block or allow, specified in Classless Inter-Domain Routing (CIDR) notation. An example of a single email address is 10.0.0.1. An example of a range of IP addresses is 10.0.0.1/24. For more information about CIDR notation, see RFC 2317.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

See Also

- Using Amazon SES Configuration Sets in the *Amazon Simple Email Service Developer Guide*
- ReceiptIpFilter in the *Amazon Simple Email Service API Reference*

AWS::SES::ReceiptRule

The `AWS::SES::ReceiptRule` resource specifies which actions Amazon SES should take when it receives mail on behalf of one or more email addresses or domains that you own. For more information, see Creating Receipt Rules for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SES::ReceiptRule",
  "Properties" : {
    "After" : String,
    "Rule" : Rule (p. 2111),
    "RuleSetName" : String
  }
}
```

YAML

```
Type: "AWS::SES::ReceiptRule"
Properties:
  After: String
  Rule: Rule (p. 2111)
  RuleSetName: String
```

Properties

`After`

The name of an existing rule after which the new rule will be placed. If this parameter is null, the new rule will be inserted at the beginning of the rule list.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Rule`

The specified rule's name, actions, recipients, domains, enabled status, scan status, and TLS policy.

Required: Yes

Type: Rule (p. 2111)

Update requires: No interruption (p. 120)

`RuleSetName`

The name of the rule set that the receipt rule will be added to.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "AWS SES ReceiptRule Sample Template",
    "Parameters": {
        "RuleSetName": {
            "Type": "String"
        },
        "ReceiptRuleName1": {
            "Type": "String"
        },
        "ReceiptRuleName2": {
            "Type": "String"
        },
        "TlsPolicy": {
            "Type": "String"
        },
        "HeaderName": {
            "Type": "String"
        },
        "HeaderValue": {
            "Type": "String"
        }
    },
    "Resources": {
        "ReceiptRule1": {
            "Type": "AWS::SES::ReceiptRule",
            "Properties": {
                "RuleSetName": {
```

```
                    "Ref": "RuleSetName"
                },
                "Rule": {
                    "Name": {
                        "Ref": "ReceiptRuleName1"

Amazon Simple Email Service ReceiptRule Action

The `Action` property type specifies an action for Amazon SES to take when it receives an email on behalf of one or more email addresses or domains that you own.

`Action` is a property of the Amazon Simple Email Service ReceiptRule Rule (p. 2111) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "BounceAction" : BounceAction (p. 2108),
  "S3Action" : S3Action (p. 2113),
  "StopAction" : StopAction (p. 2116),
  "SNSAction" : SNSAction (p. 2115),
  "WorkmailAction" : WorkmailAction (p. 2117),
  "AddHeaderAction" : AddHeaderAction (p. 2107),
  "LambdaAction" : LambdaAction (p. 2109)
}
```

YAML

```
BounceAction: BounceAction (p. 2108)
S3Action: S3Action (p. 2113)
StopAction: StopAction (p. 2116)
```

```
SNSAction: SNSAction (p. 2115)
WorkmailAction: WorkmailAction (p. 2117)
AddHeaderAction: AddHeaderAction (p. 2107)
LambdaAction: LambdaAction (p. 2109)
```

Properties

`AddHeaderAction`

Adds a header to the received email.

Required: No

Type: AddHeaderAction (p. 2107)

Update requires: No interruption (p. 120)

`BounceAction`

Rejects the received email by returning a bounce response to the sender and, optionally, publishes a notification to Amazon SNS.

Required: No

Type: BounceAction (p. 2108)

Update requires: No interruption (p. 120)

`LambdaAction`

Calls an AWS Lambda function, and optionally, publishes a notification to Amazon SNS.

Required: No

Type: LambdaAction (p. 2109)

Update requires: No interruption (p. 120)

`S3Action`

Saves the received message to an Amazon S3 bucket and, optionally, publishes a notification to Amazon SNS.

Required: No

Type: S3Action (p. 2113)

Update requires: No interruption (p. 120)

`SNSAction`

Publishes the email content within a notification to Amazon SNS.

Required: No

Type: SNSAction (p. 2115)

Update requires: No interruption (p. 120)

`StopAction`

Terminates the evaluation of the receipt rule set and optionally publishes a notification to Amazon SNS.

Required: No

Type: StopAction (p. 2116)

Update requires: No interruption (p. 120)

`WorkmailAction`

Calls Amazon WorkMail and, optionally, publishes a notification to Amazon SNS.

Required: No

Type: WorkmailAction (p. 2117)

Update requires: No interruption (p. 120)

See Also

- ReceiptAction in the *Amazon Simple Email Service API Reference*

Amazon Simple Email Service ReceiptRule AddHeaderAction

The `AddHeaderAction` property type add a header to email it recieves on behalf of one or more email addresses or domains that you own.

`AddHeaderAction` is a property of the Amazon Simple Email Service ReceiptRule Action (p. 2105) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "HeaderValue" : String,
  "HeaderName" : String
}
```

YAML

```
HeaderValue: String
HeaderName: String
```

Properties

`HeaderName`

The name of the header to add. Must be between 1 and 50 characters, inclusive, and consist of alphanumeric (a-z, A-Z, 0-9) characters and dashes only.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`HeaderValue`

Must be less than 2048 characters, and must not contain newline characters ("\r" or "\n").

Required: Yes

Type: String

Update requires: No interruption (p. 120)

See Also

- Creating Receipt Rules for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*
- CreateReceiptRule in the *Amazon Simple Email Service API Reference*
- AddHeaderAction in the *Amazon Simple Email Service API Reference*

Amazon Simple Email Service ReceiptRule BounceAction

The `BounceAction` property type includes an action in an Amazon SES receipt rule that rejects the received email by returning a bounce response to the sender and, optionally, publishes a notification to Amazon SNS.

`BounceAction` is a property of the Amazon Simple Email Service ReceiptRule Action (p. 2105) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Sender" : String,
  "SmtpReplyCode" : String,
  "Message" : String,
  "TopicArn" : String,
  "StatusCode" : String
}
```

YAML

```
Sender: String
SmtpReplyCode: String
Message: String
TopicArn: String
StatusCode: String
```

Properties

`Message`

Human-readable text to include in the bounce message.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Sender`

The email address of the sender of the bounced email. This is the address from which the bounce message will be sent.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`SmtpReplyCode`

The SMTP reply code, as defined by RFC 5321.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`TopicArn`

The Amazon Resource Name (ARN) of the Amazon SNS topic to notify when the bounce action is taken. An example of an Amazon SNS topic ARN is `arn:aws:sns:us-west-2:123456789012:MyTopic`. For more information about Amazon SNS topics, see Create a Topic in the *Amazon Simple Notification Service Developer Guide*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`StatusCode`

The SMTP enhanced status code, as defined by RFC 3463.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- Creating Receipt Rules for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*

- BounceAction in the *Amazon Simple Email Service API Reference*

Amazon Simple Email Service ReceiptRule LambdaAction

The `LambdaAction` property type includes an action in an Amazon SES receipt rule that calls an AWS Lambda function and, optionally, publishes a notification to Amazon SNS.

To enable Amazon SES to call your AWS Lambda function or to publish to an Amazon SNS topic of another account, Amazon SES must have permission to access those resources. For information about giving permissions, see Giving Permissions to Amazon SES for Email Receiving in the *Amazon Simple Email Service Developer Guide*. For information about using AWS Lambda actions in receipt rules, see Lambda Action in the *Amazon Simple Email Service Developer Guide*.

`LambdaAction` is a property of the Amazon Simple Email Service ReceiptRule Action (p. 2105) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "FunctionArn" : String,
  "TopicArn" : String,
  "InvocationType" : String
}
```

YAML

```
FunctionArn: String
TopicArn: String
InvocationType: String
```

Properties

`FunctionArn`

The Amazon Resource Name (ARN) of the AWS Lambda function. An example of an AWS Lambda function ARN is `arn:aws:lambda:us-west-2:account-id:function:MyFunction`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`InvocationType`

The invocation type of the AWS Lambda function. An invocation type of `RequestResponse` means that the execution of the function will immediately result in a response, and a value of `Event` means that the function will be invoked asynchronously. The default value is `Event`. For information about AWS Lambda invocation types, see Invoke in the *AWS Lambda Developer Guide*.

Valid values include `Event` and `RequestResponse`.

> **Important**
> There is a 30-second timeout on `RequestResponse` invocations. You should use `Event` invocation in most cases. Use `RequestResponse` only when you want to make a mail flow decision, such as whether to stop the receipt rule or the receipt rule set.

Required: No

Type: String

Update requires: No interruption (p. 120)

`TopicArn`

The Amazon Resource Name (ARN) of the Amazon SNS topic to notify when the Lambda action is taken. An example of an Amazon SNS topic ARN is `arn:aws:sns:us-west-2:123456789012:MyTopic`.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

Amazon Simple Email Service ReceiptRule Rule

The `Rule` property type specifies which actions Amazon SES should take when it receives mail on behalf of one or more email addresses or domains that you own.

Each receipt rule defines a set of email addresses or domains that it applies to. If the email addresses or domains match at least one recipient address of the message, Amazon SES executes all of the receipt rule's actions on the message.

For more information, see Creating Receipt Rules for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*.

`Rule` is a property of the AWS::SES::ReceiptRule (p. 2102) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ScanEnabled" : Boolean,
  "Recipients" : [ String, ... ],
  "Actions" : [ Action (p. 2105), ... ],
  "Enabled" : Boolean,
  "Name" : String,
  "TlsPolicy" : String
}
```

YAML

```
ScanEnabled: Boolean
Recipients:
  - String
Actions:
  - Action (p. 2105)
Enabled: Boolean
```

```
Name: String
TlsPolicy: String
```

Properties

`Actions`

An ordered list of actions to perform on messages that match at least one of the recipient email addresses or domains specified in the receipt rule.

Required: No

Type: List of Action (p. 2105)

Update requires: No interruption (p. 120)

`Enabled`

If `true`, the receipt rule is active. The default value is `false`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Name`

The name of the receipt rule. The name must:

- Contain only ASCII letters (a-z, A-Z), numbers (0-9), underscores (_), or dashes (-).
- Start and end with a letter or number.
- Contain less than 64 characters.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Recipients`

The recipient domains and email addresses that the receipt rule applies to. If this field is not specified, this rule will match all recipients under all verified domains.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`ScanEnabled`

If `true`, then messages that this receipt rule applies to are scanned for spam and viruses. The default value is `false`.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`TlsPolicy`

Specifies whether Amazon SES should require that incoming email is delivered over a connection encrypted with Transport Layer Security (TLS). If this parameter is set to `Require`, Amazon SES will bounce emails that are not received over TLS. The default is `Optional`.

Valid values include `Optional` and `Require`.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- Creating Receipt Rules for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*
- CreateReceiptRule in the *Amazon Simple Email Service API Reference*
- ReceiptRule in the *Amazon Simple Email Service API Reference*

Amazon Simple Email Service ReceiptRule S3Action

The `S3Action` property type includes an action in an Amazon SES receipt rule that saves the received message to an Amazon S3 bucket and, optionally, publishes a notification to Amazon SNS.

To enable Amazon SES to write emails to your Amazon S3 bucket, use an AWS KMS key to encrypt your emails, or publish to an Amazon SNS topic of another account, Amazon SES must have permission to access those resources. For information about giving permissions, see Giving Permissions to Amazon SES for Email Receiving in the *Amazon Simple Email Service Developer Guide*.

> **Note**
> When you save your emails to an Amazon S3 bucket, the maximum email size (including headers) is 30 MB. Emails larger than that will bounce.

For information, see S3 Action in the *Amazon Simple Email Service Developer Guide*.

`S3Action` is a property of the Amazon Simple Email Service ReceiptRule Action (p. 2105) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "BucketName" : String,
  "KmsKeyArn" : String,
  "TopicArn" : String,
  "ObjectKeyPrefix" : String
}
```

YAML

```
BucketName: String
KmsKeyArn: String
TopicArn: String
ObjectKeyPrefix: String
```

Properties

`BucketName`

The name of the Amazon S3 bucket that incoming email will be saved to.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`KmsKeyArn`

The customer master key that Amazon SES should use to encrypt your emails before saving them to the Amazon S3 bucket. You can use the default master key or a custom master key you created in AWS KMS as follows:

- To use the default master key, provide an ARN in the form of `arn:aws:kms:REGION:ACCOUNT-ID-WITHOUT-HYPHENS:alias/aws/ses`. For example, if your AWS account ID is `123456789012` and you want to use the default master key in the US West (Oregon) region, the ARN of the default master key would be `arn:aws:kms:us-west-2:123456789012:alias/aws/ses`. If you use the default master key, you don't need to perform any extra steps to give Amazon SES permission to use the key.
- To use a custom master key you created in AWS KMS, provide the ARN of the master key and ensure that you add a statement to your key's policy to give Amazon SES permission to use it. For more information about giving permissions, see Giving Permissions to Amazon SES for Email Receiving in the *Amazon Simple Email Service Developer Guide*.

For more information about key policies, see AWS Key Management Service Concepts in the *AWS Key Management Service Developer Guide*. If you do not specify a master key, Amazon SES will not encrypt your emails.

> **Important**
> Your mail is encrypted by Amazon SES using the Amazon S3 encryption client before the mail is submitted to Amazon S3 for storage. It is not encrypted using Amazon S3 server-side encryption. This means that you must use the Amazon S3 encryption client to decrypt the email after retrieving it from Amazon S3, as the service has no access to use your AWS KMS keys for decryption. This encryption client is currently available with the AWS SDK for Java and AWS SDK for Ruby only. For more information about client-side encryption using AWS KMS master keys, see Protecting Data Using Client-Side Encryption in the *Amazon Simple Storage Service Developer Guide*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ObjectKeyPrefix`

The key prefix of the Amazon S3 bucket. The key prefix is similar to a directory name that enables you to store similar data under the same directory in a bucket.

Required: No

Type: String

Update requires: No interruption (p. 120)

`TopicArn`

The ARN of the Amazon SNS topic to notify when the message is saved to the Amazon S3 bucket. An example of an Amazon SNS topic ARN is `arn:aws:sns:us-west-2:123456789012:MyTopic`.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

Amazon Simple Email Service ReceiptRule SNSAction

The `SNSAction` property type includes an action in an Amazon SES receipt rule that publishes a notification to Amazon SNS.

If you own the Amazon SNS topic, you don't need to do anything to give Amazon SES permission to publish emails to it. However, if you don't own the Amazon SNS topic, you need to attach a policy to the topic to give Amazon SES permissions to access it. For information about giving permissions, see Giving Permissions to Amazon SES for Email Receiving in the *Amazon Simple Email Service Developer Guide*.

> **Important**
> You can only publish emails that are 150 KB or less (including the header) to Amazon SNS. Larger emails will bounce. If you anticipate emails larger than 150 KB, use the S3 action instead.

For more information, see SNS Action in the *Amazon Simple Email Service Developer Guide*.

`SNSAction` is a property of the Amazon Simple Email Service ReceiptRule Action (p. 2105) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "TopicArn" : String,
  "Encoding" : String
}
```

YAML

```
TopicArn: String
Encoding: String
```

Properties

`Encoding`

The encoding to use for the email within the Amazon SNS notification. UTF-8 is easier to use, but may not preserve all special characters when a message was encoded with a different encoding format. Base64 preserves all special characters. The default value is UTF-8.

Valid values include `Base64` and `UTF-8`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`TopicArn`

The Amazon Resource Name (ARN) of the Amazon SNS topic to notify. An example of an Amazon SNS topic ARN is `arn:aws:sns:us-west-2:123456789012:MyTopic`.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

Amazon Simple Email Service ReceiptRule StopAction

The `StopAction` property type includes an action in an Amazon SES receipt rule that terminates the evaluation of the receipt rule set and, optionally, publishes a notification to Amazon SNS.

`StopAction` is a property of the Amazon Simple Email Service ReceiptRule Action (p. 2105) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Scope" : String,
  "TopicArn" : String
}
```

YAML

```
Scope: String
TopicArn: String
```

Properties

`Scope`

The name of the RuleSet that is being stopped.

Valid values include: `RuleSet`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`TopicArn`

The Amazon Resource Name (ARN) of the Amazon SNS topic to notify when the stop action is taken. An example of an Amazon SNS topic ARN is `arn:aws:sns:us-west-2:123456789012:MyTopic`.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- Creating Receipt Rules for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*
- StopAction in the *Amazon Simple Email Service API Reference*

Amazon Simple Email Service ReceiptRule WorkmailAction

The `WorkmailAction` property type includes an action in an Amazon SES receipt rule that calls Amazon WorkMail and, optionally, publishes a notification to Amazon SNS.

You will typically not use this action directly because Amazon WorkMail adds the rule automatically during its setup procedure.

For information using a receipt rule to call Amazon WorkMail, see WorkMail Action in the *Amazon Simple Email Service Developer Guide*.

`WorkmailAction` is a property of the Amazon Simple Email Service ReceiptRule Action (p. 2105) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "TopicArn" : String,
  "OrganizationArn" : String
}
```

YAML

```
TopicArn: String
OrganizationArn: String
```

Properties

`OrganizationArn`

The ARN of the Amazon WorkMail organization. An example of an Amazon WorkMail organization ARN is `arn:aws:workmail:us-west-2:123456789012:organization/m-68755160c4cb4e29a2b2f8fb58f359d7`. For information about Amazon WorkMail organizations, see Working with Organizations in the *Amazon WorkMail Administrator Guide*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`TopicArn`

The Amazon Resource Name (ARN) of the Amazon SNS topic to notify when the WorkMail action is called. An example of an Amazon SNS topic ARN is `arn:aws:sns:us-west-2:123456789012:MyTopic`.

Required: No

Type: String

Update requires: No interruption (p. 120)

See Also

- Creating Receipt Rules for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*
- WorkMail Action in the *Amazon Simple Email Service Developer Guide*
- WorkmailAction in the *Amazon Simple Email Service API Reference*

AWS::SES::ReceiptRuleSet

The `AWS::SES::ReceiptRuleSet` resource specifies an empty rule set for Amazon SES. For more information, see CreateReceiptRuleSet in the *Amazon Simple Email Service API Reference*.

Topics

- Syntax (p. 2118)
- Properties (p. 2119)
- Return Values (p. 2119)
- Example (p. 2119)
- See Also (p. 2120)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SES::ReceiptRuleSet",
  "Properties" : {
    "RuleSetName" : String
  }
}
```

YAML

```
Type: "AWS::SES::ReceiptRuleSet"
Properties:
  RuleSetName: String
```

Properties

`RuleSetName`

The name of the rule set to create. The name must:

- Contain only ASCII letters (a-z, A-Z), numbers (0-9), underscores (_), or dashes (-).
- Start and end with a letter or number.
- Contain less than 64 characters.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "AWS SES ReceiptRuleSet Sample Template",
    "Parameters": {
        "ReceiptRuleSetName": {
            "Type": "String"
        }
    },
    "Resources": {
        "ReceiptRuleSet": {
            "Type": "AWS::SES::ReceiptRuleSet",
            "Properties": {
                "RuleSetName": {
                    "Ref": "ReceiptRuleSetName"
                }
            }
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Description: 'AWS SES ReceiptRuleSet Sample Template'
Parameters:
  ReceiptRuleSetName:
    Type: String
Resources:
  ReceiptRuleSet:
    Type: AWS::SES::ReceiptRuleSet
    Properties:
      RuleSetName: !Ref ReceiptRuleSetName
```

See Also

- Creating Receipt Rules for Amazon SES Email Receiving in the *Amazon Simple Email Service Developer Guide*
- CreateReceiptRuleSet in the *Amazon Simple Email Service API Reference*

AWS::SES::Template

The `AWS::SES::Template` resource specifies the content of an email (composed of a subject line, an HTML part, and a text-only part) for Amazon SES. For more information, see Template in the *Amazon Simple Email Service API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SES::Template",
  "Properties" : {
    "Template" : Template (p. 2121)
  }
}
```

YAML

```
Type: "AWS::SES::Template"
Properties:
  Template: Template (p. 2121)
```

Properties

`Template`

The content of the email, composed of a subject line, an HTML part, and a text-only part.

Required: No

Type: Template (p. 2121)

Update requires: No interruption (p. 120)

Example

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Description": "AWS SES Template Sample Template",
    "Parameters": {
        "TemplateName": {
            "Type": "String"
        },
        "SubjectPart": {
            "Type": "String"
```

```
        },
        "TextPart": {
            "Type": "String"
        },
        "HtmlPart": {
            "Type": "String"
        }
    },
    "Resources": {
        "Template": {
            "Type": "AWS::SES::Template",
            "Properties": {
                "Template": {
                    "TemplateName": {
                        "Ref": "TemplateName"
                    },
                    "SubjectPart": {
                        "Ref": "SubjectPart"
                    },
                    "TextPart": {
                        "Ref": "TextPart"
                    },
                    "HtmlPart": {
                        "Ref": "HtmlPart"
                    }
                }
            }
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09

Amazon Simple Email Service Template Template

The `Template` property type specifies specify the content of the email (composed of a subject line, an HTML part, and a text-only part) for Amazon SES.

`Template` is a property of the AWS::SES::Template (p. 2120) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "HtmlPart" : String,
  "TextPart" : String,
  "TemplateName" : String,
  "SubjectPart" : String
}
```

YAML

```
HtmlPart: String
TextPart: String
TemplateName: String
SubjectPart: String
```

Properties

`HtmlPart`

The HTML body of the email.

Required: No

Type: String

Update requires: No interruption (p. 120)

`SubjectPart`

The subject line of the email.

Required: No

Type: String

Update requires: No interruption (p. 120)

`TextPart`

The email body that will be visible to recipients whose email clients do not display HTML.

Required: No

Type: String

Update requires: No interruption (p. 120)

`TemplateName`

The name of the template. You will refer to this name when you send email using the `SendTemplatedEmail` or `SendBulkTemplatedEmail` operations.

Required: No

Type: String

Update requires: Replacement (p. 121)

See Also

- Template in the *Amazon Simple Email Service API Reference*
- SendTemplatedEmail in the *Amazon Simple Email Service API Reference*
- SendBulkTemplatedEmail in the *Amazon Simple Email Service API Reference*

Amazon SimpleDB Resource Types Reference

This section contains reference information for all Amazon SimpleDB resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::SDB::data-type-name
```

Topics

- AWS::SDB::Domain (p. 2123)

AWS::SDB::Domain

Use the `AWS::SDB::Domain` resource to declare an Amazon SimpleDB domain. When you specify `AWS::SDB::Domain` as an argument in a `Ref` function, AWS CloudFormation returns the value of the `DomainName`.

> **Important**
> The `AWS::SDB::Domain` resource does not allow any updates, including metadata updates.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SDB::Domain",
  "Properties" : {
    "Description" : String
  }
}
```

YAML

```
Type: AWS::SDB::Domain
Properties:
  Description: String
```

Properties

`Description`

Information about the Amazon SimpleDB domain.

Required: No

Type: String

Update requires: Updates are not supported.

Amazon Simple Notification Service Resource Types Reference

This section contains reference information for all Amazon Simple Notification Service resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::SNS::data-type-name
```

Topics

- AWS::SNS::Subscription (p. 2124)
- AWS::SNS::Topic (p. 2128)
- AWS::SNS::TopicPolicy (p. 2131)

AWS::SNS::Subscription

The `AWS::SNS::Subscription` resource subscribes an endpoint to an Amazon Simple Notification Service (Amazon SNS) topic. The owner of the endpoint must confirm the subscription before Amazon SNS creates the subscription.

Topics

- Syntax (p. 2124)
- Properties (p. 2125)
- Example (p. 2126)

Syntax

JSON

```
{
  "Type" : "AWS::SNS::Subscription",
  "Properties" : {
    "DeliveryPolicy" : JSON object,
    "Endpoint" : String,
    "FilterPolicy" : JSON object,
    "Protocol" : String,
    "RawMessageDelivery" : Boolean,
    "Region" : String,
    "TopicArn" : String
  }
}
```

YAML

```
Type: "AWS::SNS::Subscription"
```

```
Properties:
  DeliveryPolicy: JSON object
  Endpoint: String
  FilterPolicy: JSON object
  Protocol: String
  RawMessageDelivery: Boolean,
  Region: String
  TopicArn: String
```

Properties

`DeliveryPolicy`

The JSON serialization of the subscription's delivery policy. For more information, see GetSubscriptionAttributes in the *Amazon Simple Notification Service API Reference*.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`Endpoint`

The endpoint that receives notifications from the Amazon SNS topic. The endpoint value depends on the protocol that you specify. For more information, see the Subscribe Endpoint parameter in the *Amazon Simple Notification Service API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`FilterPolicy`

The filter policy JSON that is assigned to the subscription. For more information, see GetSubscriptionAttributes in the *Amazon Simple Notification Service API Reference*.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`Protocol`

The subscription's protocol. For more information, see the Subscribe Protocol parameter in the *Amazon Simple Notification Service API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`RawMessageDelivery`

`true` if raw message delivery is enabled for the subscription. Raw messages are free of JSON formatting and can be sent to HTTP/S and Amazon SQS endpoints. For more information, see GetSubscriptionAttributes in the *Amazon Simple Notification Service API Reference*.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`Region`

The region in which the topic resides.

Required: No

Type: String

Update requires: Replacement (p. 121)

`TopicArn`

The Amazon Resource Name (ARN) of the topic to subscribe to.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Example

Create a subscription with mandatory attributes

The following example creates a subscription with Endpoint, Protocol and TopicArn only.

JSON

```
"MySubscription" : {
  "Type" : "AWS::SNS::Subscription",
  "Properties" : {
    "Endpoint" : "test@email.com",
    "Protocol" : "email",
    "TopicArn" : {"Ref" : "MySNSTopic"}
  }
}
```

YAML

```
MySubscription:
  Type: AWS::SNS::Subscription
  Properties:
    Endpoint: test@email.com
    Protocol: email
    TopicArn: !Ref 'MySNSTopic'
```

Create a subscription with optional attributes

The following example creates a subscription with FilterPolicy, DeliveryPolicy and RawMessageDelivery.

Note that SNS subscription attributes can be set on standalone SNS subscriptions only, as opposed to SNS subscriptions nested in SNS topics.

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
```

```
"Resources": {
    "CarSalesTopic": {
        "Type": "AWS::SNS::Topic"
    },

          numMinDelayRetries: 3
          numMaxDelayRetries: 17
          numNoDelayRetries: 0
          backoffFunction: exponential
  ERPIntegrationQueue:
    Type: 'AWS::SQS::Queue'
    Properties: {}
  CRMIntegrationQueue:
    Type: 'AWS::SQS::Queue'
    Properties: {}
Parameters:
  myHttpEndpoint:
    Type: String
```

AWS::SNS::Topic

The `AWS::SNS::Topic` type creates an Amazon Simple Notification Service (Amazon SNS) topic.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SNS::Topic",
  "Properties" : {
    "DisplayName" : String,
    "Subscription" : [ SNS Subscription, ... ],
    "TopicName" : String
  }
}
```

YAML

```
Type: AWS::SNS::Topic
Properties:
  DisplayName: String
  Subscription:
    - SNS Subscription
  TopicName: String
```

Properties

`DisplayName`

A developer-defined string that can be used to identify this SNS topic.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Subscription`

The SNS subscriptions (endpoints) for this topic.

Required: No

Type: List of SNS Subscriptions (p. 2131)

Update requires: No interruption (p. 120)

`TopicName`

A name for the topic. If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the topic name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

For the `AWS::SNS::Topic` resource, the `Ref` intrinsic function returns the topic ARN, for example: `arn:aws:sns:us-east-1:123456789012:mystack-mytopic-NZJ5JSMVGFIE`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`TopicName`

Returns the name for an Amazon SNS topic.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

An example of an SNS topic subscribed to by two SQS queues:

JSON

```
"MySNSTopic" : {
   "Type" : "AWS::SNS::Topic",
   "Properties" : {
      "Subscription" : [
         { "Endpoint" : { "Fn::GetAtt" : [ "MyQueue1", "Arn" ] }, "Protocol" : "sqs" },
         { "Endpoint" : { "Fn::GetAtt" : [ "MyQueue2", "Arn" ] }, "Protocol" : "sqs" }
      ],
      "TopicName" : "SampleTopic"
   }
}
```

YAML

```
MySNSTopic:
  Type: AWS::SNS::Topic
  Properties:
    Subscription:
      -
        Endpoint:
          Fn::GetAtt:
            - "MyQueue1"
            - "Arn"
        Protocol: "sqs"
      -
        Endpoint:
          Fn::GetAtt:
            - "MyQueue2"
            - "Arn"
        Protocol: "sqs"
    TopicName: "SampleTopic"
```

- Using an AWS CloudFormation Template to Create a Topic that Sends Messages to Amazon SQS Queues in the *Amazon Simple Notification Service Developer Guide*

Amazon SNS Subscription Property Type

`Subscription` is an embedded property of the `AWS::SNS::Topic` (p. 2128) resource that describes the subscription endpoints for an Amazon Simple Notification Service (Amazon SNS) topic.

Syntax

JSON

```
{
  "Endpoint" : String,
  "Protocol" : String
}
```

YAML

```
Endpoint: String
Protocol: String
```

Properties

`Endpoint`

The subscription's endpoint (format depends on the protocol). For more information, see the Subscribe Endpoint parameter in the *Amazon Simple Notification Service API Reference*.

Required: Yes

Type: String

`Protocol`

The subscription's protocol. For more information, see the Subscribe Protocol parameter in the *Amazon Simple Notification Service API Reference*.

Required: Yes

Type: String

AWS::SNS::TopicPolicy

The `AWS::SNS::TopicPolicy` resource associates Amazon SNS topics with a policy.

Topics

- Syntax (p. 2131)
- Properties (p. 2132)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SNS::TopicPolicy",
  "Properties" :
    {
      "PolicyDocument" : PolicyDocument,
      "Topics" : [ List of SNS topic ARNs, ... ]
    }
}
```

YAML

```
Type: AWS::SNS::TopicPolicy
Properties:
  PolicyDocument: PolicyDocument
  Topics:
    - List of SNS topic ARNs
```

Properties

`PolicyDocument`

A policy document that contains permissions to add to the specified SNS topics.

Required: Yes

JSON or YAML

Update requires: No interruption (p. 120)

`Topics`

The Amazon Resource Names (ARN) of the topics to which you want to add the policy. You can use the Ref function (p. 2341) to specify an AWS::SNS::Topic (p. 2128) resource.

Required: Yes

Type: A list of Amazon SNS topics ARNs

Update requires: No interruption (p. 120)

For sample `AWS::SNS::TopicPolicy` snippets, see Declaring an Amazon SNS Topic Policy (p. 401).

Amazon Simple Queue Service Resource Types Reference

This section contains reference information for all Amazon Simple Queue Service resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::SQS::data-type-name
```

Topics

- AWS::SQS::Queue (p. 2133)

- AWS::SQS::QueuePolicy (p. 2141)

AWS::SQS::Queue

The `AWS::SQS::Queue` resource creates an Amazon Simple Queue Service (Amazon SQS) queue.

For more information about creating FIFO (first-in-first-out) queues, see the tutorial Create a queue using AWS CloudFormation in the *Amazon Simple Queue Service Developer Guide*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::SQS::Queue",
   "Properties" : {
      "ContentBasedDeduplication" : Boolean,
      "DelaySeconds": Integer,
      "FifoQueue" : Boolean,
      "KmsMasterKeyId": String,
      "KmsDataKeyReusePeriodSeconds": Integer,
      "MaximumMessageSize": Integer,
      "MessageRetentionPeriod": Integer,
      "QueueName": String,
      "ReceiveMessageWaitTimeSeconds": Integer,
      "RedrivePolicy": RedrivePolicy,
      "Tags" : [ Resource Tag, ... ],
      "VisibilityTimeout": Integer
   }
}
```

YAML

```
Type: AWS::SQS::Queue
Properties:
  ContentBasedDeduplication: Boolean
  DelaySeconds: Integer
  FifoQueue: Boolean
  KmsMasterKeyId: String
  KmsDataKeyReusePeriodSeconds: Integer
  MaximumMessageSize: Integer
  MessageRetentionPeriod: Integer
  QueueName: String
  ReceiveMessageWaitTimeSeconds: Integer
  RedrivePolicy:
    RedrivePolicy
  Tags:
    Resource Tag
  VisibilityTimeout: Integer
```

Properties

`ContentBasedDeduplication`

For first-in-first-out (FIFO) queues, specifies whether to enable content-based deduplication. During the deduplication interval, Amazon SQS treats messages that are sent with identical

content as duplicates and delivers only one copy of the message. For more information, see the `ContentBasedDeduplication` attribute for the CreateQueue action in the *Amazon Simple Queue Service API Reference*.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`DelaySeconds`

The time in seconds that the delivery of all messages in the queue is delayed. You can specify an integer value of `0` to `900` (15 minutes). The default value is `0`.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`FifoQueue`

If set to `true`, creates a FIFO queue. If you don't specify this property, Amazon SQS creates a standard queue. For more information, see FIFO (First-In-First-Out) Queues in the *Amazon Simple Queue Service Developer Guide*.

Required: No

Type: Boolean

Update requires: Replacement (p. 121)

`KmsMasterKeyId`

The ID of an AWS managed customer master key (CMK) for Amazon SQS or a custom CMK. To use the AWS managed CMK for Amazon SQS, specify the alias `alias/aws/sqs`. For more information, see CreateQueue in the *Amazon Simple Queue Service API Reference*, Protecting Data Using Server-Side Encryption (SSE) and AWS KMS in the *Amazon Simple Queue Service Developer Guide*, or **Customer Master Keys** in the AWS Key Management Service Best Practices whitepaper.

Required: No

Type: String

Update requires: No interruption (p. 120)

`KmsDataKeyReusePeriodSeconds`

The length of time in seconds that Amazon SQS can reuse a data key to encrypt or decrypt messages before calling AWS KMS again. The value must be an integer between 60 (1 minute) and 86,400 (24 hours). The default is 300 (5 minutes).

> **Note**
> A shorter time period provides better security, but results in more calls to AWS KMS, which might incur charges after Free Tier. For more information, see How Does the Data Key Reuse Period Work? in the *Amazon Simple Queue Service Developer Guide*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`MaximumMessageSize`

The limit of how many bytes that a message can contain before Amazon SQS rejects it. You can specify an integer value from `1024` bytes (1 KiB) to `262144` bytes (256 KiB). The default value is `262144` (256 KiB).

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`MessageRetentionPeriod`

The number of seconds that Amazon SQS retains a message. You can specify an integer value from `60` seconds (1 minute) to `1209600` seconds (14 days). The default value is `345600` seconds (4 days).

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`QueueName`

A name for the queue. To create a FIFO queue, the name of your FIFO queue must end with the `.fifo` suffix. For more information, see FIFO (First-In-First-Out) Queues in the *Amazon Simple Queue Service Developer Guide*.

If you don't specify a name, AWS CloudFormation generates a unique physical ID and uses that ID for the queue name. For more information, see Name Type (p. 2256).

> **Important**
> If you specify a name, you cannot perform updates that require replacement of this resource. You can perform updates that require no or some interruption. If you must replace the resource, specify a new name.

Required: No

Type: String

Update requires: Replacement (p. 121)

`ReceiveMessageWaitTimeSeconds`

Specifies the duration, in seconds, that the `ReceiveMessage` action call waits until a message is in the queue in order to include it in the response, as opposed to returning an empty response if a message isn't yet available. You can specify an integer from `1` to `20`. The short polling is used as the default or when you specify `0` for this property. For more information, see Amazon SQS Long Poll.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`RedrivePolicy`

Specifies an existing dead letter queue to receive messages after the source queue (this queue) fails to process a message a specified number of times.

Required: No

Type: Amazon SQS RedrivePolicy (p. 2140)

Update requires: No interruption (p. 120)

`Tags`

The tags that you want to attach to this queue.

Required: No

Type: A list of resource tags (p. 2258)

Update requires: No interruption (p. 120)

`VisibilityTimeout`

The length of time during which a message will be unavailable after a message is delivered from the queue. This blocks other components from receiving the same message and gives the initial component time to process and delete the message from the queue.

Values must be from 0 to 43200 seconds (12 hours). If you don't specify a value, AWS CloudFormation uses the default value of 30 seconds.

For more information about Amazon SQS queue visibility timeouts, see Visibility Timeout in the *Amazon Simple Queue Service Developer Guide*.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

Return Values

Ref

The `AWS::SQS::Queue` type returns the queue URL. For example: `https://sqs.us-east-2.amazonaws.com/123456789012/aa4-MyQueue-Z5NOSZO2PZE9`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Arn`

Returns the Amazon Resource Name (ARN) of the queue. For example: `arn:aws:sqs:us-east-2:123456789012:mystack-myqueue-15PG5C2FC1CW8`.

`QueueName`

Returns the queue name. For example:

`mystack-myqueue-1VF9BKQH5BJVI`

Examples

SQS Queue with Cloudwatch Alarms

JSON

```
{
```

```
 "AWSTemplateFormatVersion" : "2010-09-09",

Parameters:
  AlarmEmail:
    Default: "nobody@amazon.com"
    Description: "Email address to notify if operational problems arise"
    Type: "String"
Resources:
  MyQueue:
    Type: AWS::SQS::Queue
    Properties:
      QueueName: "SampleQueue"
  AlarmTopic:
    Type: AWS::SNS::Topic
    Properties:
      Subscription:
        -
          Endpoint:
            Ref: "AlarmEmail"
          Protocol: "email"
  QueueDepthAlarm:
    Type: AWS::CloudWatch::Alarm
    Properties:
      AlarmDescription: "Alarm if queue depth grows beyond 10 messages"
      Namespace: "AWS/SQS"
      MetricName: "ApproximateNumberOfMessagesVisible"
      Dimensions:
        -
          Name: "QueueName"
          Value:
            Fn::GetAtt:
              - "MyQueue"
              - "QueueName"
      Statistic: "Sum"
      Period: "300"
      EvaluationPeriods: "1"
      Threshold: "10"
      ComparisonOperator: "GreaterThanThreshold"
      AlarmActions:
        -
          Ref: "AlarmTopic"
      InsufficientDataActions:
        -
          Ref: "AlarmTopic"
Outputs:
  QueueURL:
    Description: "URL of newly created SQS Queue"
    Value:
      Ref: "MyQueue"
  QueueARN:
    Description: "ARN of newly created SQS Queue"
    Value:
```

```
      Fn::GetAtt:
        - "MyQueue"
        - "Arn"
  QueueName:
    Description: "Name newly created SQS Queue"
    Value:
      Fn::GetAtt:
        - "MyQueue"
        - "QueueName"
```

SQS Queue with a Dead Letter Queue

The following sample creates a source queue and a dead letter queue. Because the source queue specifies the dead letter queue in its redrive policy, the source queue is dependent on the creation of the dead letter queue.

JSON

```
{
  "AWSTemplateFormatVersion" : "2010-09-09",

  "Resources" : {
    "MySourceQueue" : {
      "Type" : "AWS::SQS::Queue",
      "Properties" : {
        "RedrivePolicy": {
          "deadLetterTargetArn" : {"Fn::GetAtt" : [ "MyDeadLetterQueue" , "Arn" ]},
          "maxReceiveCount" : 5
        }
      }
    },
    "MyDeadLetterQueue" : {
      "Type" : "AWS::SQS::Queue"
    }
  },

  "Outputs" : {
    "SourceQueueURL" : {
      "Description" : "URL of the source queue",
      "Value" : { "Ref" : "MySourceQueue" }
    },
    "SourceQueueARN" : {
      "Description" : "ARN of the source queue",
      "Value" : { "Fn::GetAtt" : ["MySourceQueue", "Arn"]}
    },
    "DeadLetterQueueURL" : {
      "Description" : "URL of the dead letter queue",
      "Value" : { "Ref" : "MyDeadLetterQueue" }
    },
    "DeadLetterQueueARN" : {
      "Description" : "ARN of the dead letter queue",
      "Value" : { "Fn::GetAtt" : ["MyDeadLetterQueue", "Arn"]}
    }
  }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Resources:
  MySourceQueue:
    Type: AWS::SQS::Queue
```

```
    Properties:
      RedrivePolicy:
        deadLetterTargetArn:
          Fn::GetAtt:
            - "MyDeadLetterQueue"
            - "Arn"
        maxReceiveCount: 5
  MyDeadLetterQueue:
    Type: AWS::SQS::Queue
Outputs:
  SourceQueueURL:
    Description: "URL of the source queue"
    Value:
      Ref: "MySourceQueue"
  SourceQueueARN:
    Description: "ARN of the source queue"
    Value:
      Fn::GetAtt:
        - "MySourceQueue"
        - "Arn"
  DeadLetterQueueURL:
    Description: "URL of the dead letter queue"
    Value:
      Ref: "MyDeadLetterQueue"
  DeadLetterQueueARN:
    Description: "ARN of the dead letter queue"
    Value:
      Fn::GetAtt:
        - "MyDeadLetterQueue"
        - "Arn"
```

Amazon SQS RedrivePolicy

The `RedrivePolicy` type is a property of the AWS::SQS::Queue (p. 2133) resource. A redrive policy defines the parameters for the dead letter queue functionality of the source queue. For more information about the redrive policy and dead letter queues, see Using Amazon SQS Dead Letter Queues in the *Amazon Simple Queue Service Developer Guide*.

Syntax

JSON

```
{
  "deadLetterTargetArn" : String,
  "maxReceiveCount" : Integer
}
```

YAML

```
deadLetterTargetArn: String
maxReceiveCount: Integer
```

Properties

`deadLetterTargetArn`

The Amazon Resource Name (ARN) of the dead-letter queue to which Amazon SQS moves messages after the value of `maxReceiveCount` is exceeded.

Required: Yes

Type: String

`maxReceiveCount`

The number of times a message is delivered to the source queue before being moved to the dead-letter queue.

Required: Yes

Type: Integer

AWS::SQS::QueuePolicy

The AWS::SQS::QueuePolicy type applies a policy to Amazon SQS queues.

AWS::SQS::QueuePolicy Snippet: Declaring an Amazon SQS Policy (p. 402)

Topics

- Syntax (p. 2141)
- Properties (p. 2142)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
   "Type" : "AWS::SQS::QueuePolicy",
   "Properties" : {
      "PolicyDocument" : JSON,
      "Queues" : [ String, ... ]
   }
}
```

YAML

```
Type: AWS::SQS::QueuePolicy
Properties:
  PolicyDocument: JSON
  Queues:
    - String
```

Properties

`PolicyDocument`

A policy document that contains the permissions for the specified Amazon SQS queues. For more information about Amazon SQS policies, see Creating Custom Policies Using the Access Policy Language in the *Amazon Simple Queue Service Developer Guide*.

Required: Yes

Type: JSON object

Update requires: No interruption (p. 120)

`Queues`

The URLs of the queues to which you want to add the policy. You can use the Ref function (p. 2341) to specify an AWS::SQS::Queue (p. 2133) resource.

Required: Yes

Type: List of String values

Update requires: No interruption (p. 120)

AWS Step Functions Resource Types Reference

This section contains reference information for all AWS Step Functions resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::StepFunctions::data-type-name
```

Topics

- AWS::StepFunctions::Activity (p. 2142)
- AWS::StepFunctions::StateMachine (p. 2144)

AWS::StepFunctions::Activity

Use the `AWS::StepFunctions::Activity` resource to create an AWS Step Functions activity.

For information about creating an activity and creating a state machine with an activity, see Tutorial: An Activity State Machine in the *AWS Step Functions Developer Guide* and `CreateActivity` in the *AWS Step Functions API Reference*.

Syntax

JSON

```
{
   "Type": "AWS::StepFunctions::Activity",
   "Properties": {
      "Name": String
```

```
    }
}
```

YAML

```
Type: "AWS::StepFunctions::Activity"
Properties:
  Name: String
```

Properties

`Name`

The name of the activity to create. This name must be unique for your AWS account and region.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you provide the logical ID of this resource to the `Ref` intrinsic function, `Ref` returns the ARN of the created activity. For example:

```
{ "Ref": "MyActivity" }
```

Returns a value similar to the following:

```
arn:aws:states:us-east-1:111122223333:activity:myActivity
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Name`

Returns the name of the activity. For example:

```
{ "Fn::GetAtt": ["MyActivity", "Name"] }
```

Returns a value similar to the following:

```
myActivity
```

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Example

The following example creates a Step Functions activity.

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Description" : "An example template for a Step Functions activity.",
   "Resources" : {
      "MyActivity" : {
         "Type" : "AWS::StepFunctions::Activity",
         "Properties" : {
            "Name" : "myActivity"
        }
      }
   }
}
```

YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Description: "A sample template for a Step Functions activity"
Resources:
  MyActivity:
    Type: "AWS::StepFunctions::Activity"
    Properties:
      Name: myActivity
```

AWS::StepFunctions::StateMachine

Use the `AWS::StepFunctions::StateMachine` resource to create an AWS Step Functions state machine.

For information about creating state machines, see Tutorial: A Lambda State Machine in the *AWS Step Functions Developer Guide* and `CreateStateMachine` in the *AWS Step Functions API Reference*.

Syntax

JSON

```
{
   "Type": "AWS::StepFunctions::StateMachine",
   "Properties": {
      "StateMachineName": String,
      "DefinitionString": String,
      "RoleArn": String
    }
}
```

YAML

```
Type: "AWS::StepFunctions::StateMachine"
Properties:
  StateMachineName: String
  DefinitionString: String
  RoleArn: String
```

Properties

`StateMachineName`

The name of the state machine. If you do not specify a name one will be generated that is similar to `MyStateMachine-1234abcdefgh`. For more information on creating a valid name see Request Parameters in the *AWS Step Functions API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`DefinitionString`

The Amazon States Language definition of the state machine. For more information, see Amazon States Language in the *AWS Step Functions Developer Guide*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`RoleArn`

The Amazon Resource Name (ARN) of the IAM role to use for this state machine.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When you provide the logical ID of this resource to the `Ref` intrinsic function, `Ref` returns the ARN of the created state machine. For example:

```
{ "Ref": "MyStateMachine" }
```

Returns a value similar to the following:

```
arn:aws:states:us-east-1:111122223333:stateMachine:HelloWorld-StateMachine
```

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Name`

Returns the name of the state machine. For example:

```
{ "Fn::GetAtt": ["MyStateMachine", "Name"] }
```

Returns the name of your state machine:

```
HelloWorld-StateMachine
```

If you did not specify the name it will be similar to the following:

```
MyStateMachine-1234abcdefgh
```

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

The following examples create a Step Functions state machine.

JSON

Using a Single-Line Property

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Description" : "An example template for a Step Functions state machine.",
   "Resources" : {
      "MyStateMachine" : {
         "Type" : "AWS::StepFunctions::StateMachine",
         "Properties" : {
            "StateMachineName" : "HelloWorld-StateMachine",
            "DefinitionString" : "{\"StartAt\": \"HelloWorld\", \"States\":
 {\"HelloWorld\": {\"Type\": \"Task\", \"Resource\": \"arn:aws:lambda:us-
east-1:111122223333:function:HelloFunction\", \"End\": true}}}",
            "RoleArn" : "arn:aws:iam::111122223333:role/service-role/StatesExecutionRole-
us-east-1"
         }
      }
   }
}
```

Using the Fn::Join Intrinsic Function

```
{
    "AWSTemplateFormatVersion" : "2010-09-09",
    "Description" : "An example template for a Step Functions state machine.",
    "Resources": {
       "MyStateMachine": {
          "Type": "AWS::StepFunctions::StateMachine",
             "Properties": {
                "StateMachineName" : "HelloWorld-StateMachine",
                "DefinitionString" : {
                   "Fn::Join": [
                      "\n",
                      [
                         "{",
                         "    \"StartAt\": \"HelloWorld\",",
                         "    \"States\" : {",
                         "        \"HelloWorld\" : {",
                         "            \"Type\" : \"Task\", ",
```

```
                        "            \"Resource\" : \"arn:aws:lambda:us-
east-1:111122223333:function:HelloFunction\",",
                        "            \"End\" : true",
                        "         }",
                        "     }",
                        "}"
                    ]
                ]
            },
        "RoleArn" : "arn:aws:iam::111122223333:role/service-role/StatesExecutionRole-us-
east-1"
          }
      }
    }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Description: An example template for a Step Functions state machine.
Resources:
  MyStateMachine:
    Type: AWS::StepFunctions::StateMachine
    Properties:
      StateMachineName: HelloWorld-StateMachine
      DefinitionString: |-
        {
          "StartAt": "HelloWorld",
          "States": {
            "HelloWorld": {
              "Type": "Task",
              "Resource": "arn:aws:lambda:us-east-1:111122223333:function:HelloFunction",
              "End": true
            }
          }
        }
      RoleArn: arn:aws:iam::111122223333:role/service-role/StatesExecutionRole-us-east-1
```

AWS Systems Manager Resource Types Reference

This section contains reference information for all AWS Systems Manager resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::SSM::data-type-name
```

Topics

- AWS::SSM::Association (p. 2148)
- AWS::SSM::Document (p. 2152)
- AWS::SSM::MaintenanceWindow (p. 2156)
- AWS::SSM::MaintenanceWindowTarget (p. 2159)
- AWS::SSM::MaintenanceWindowTask (p. 2161)
- AWS::SSM::Parameter (p. 2174)
- AWS::SSM::PatchBaseline (p. 2177)
- AWS::SSM::ResourceDataSync (p. 2185)

AWS::SSM::Association

The `AWS::SSM::Association` resource associates an SSM document in AWS Systems Manager with EC2 instances that contain a configuration agent to process the document.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SSM::Association",
  "Properties" : {
    "AssociationName" : String,
    "DocumentVersion" : String,
    "InstanceId" : String,
    "Name" : String,
    "OutputLocation" : InstanceAssociationOutputLocation (p. 2150) ,
    "Parameters" : { String: [String, ...] },
    "ScheduleExpression" : String,
    "Targets" : [ Targets (p. 2151) ]
  }
}
```

YAML

```
Type: "AWS::SSM::Association"
Properties:
  AssociationName: String
  DocumentVersion: String
  InstanceId: String
  Name: String
  OutputLocation: InstanceAssociationOutputLocation (p. 2150)
  Parameters:
    String:
      - String
  ScheduleExpression: String
  Targets:
    - Targets (p. 2151)
```

Properties

`AssociationName`

The name of the association.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DocumentVersion`

The version of the SSM document to associate with the target.

Required: No

Type: String

Update requires: No interruption (p. 120)

`InstanceId`

The ID of the instance that the SSM document is associated with.

Required: Conditional. You must specify the `InstanceId` or `Targets` property.

Type: String

Update requires: Replacement (p. 121)

`Name`

The name of the SSM document.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`OutputLocation`

An Amazon S3 bucket where you want to store the results of this request.

Required: No

Type: InstanceAssociationOutputLocation (p. 2150)

Update requires: No interruption (p. 120)

`Parameters`

Parameter values that the SSM document uses at runtime.

Required: No

Type: String to list-of-strings map

Update requires: No interruption (p. 120)

`ScheduleExpression`

A Cron expression that specifies when the association is applied to the target. For more on working with Cron expressions, see Working with Cron and Rate Expressions for Systems Manager.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Targets`

The targets that the SSM document sends commands to.

Required: Conditional. You must specify the `InstanceId` or `Targets` property.

Type: List of AWS Systems Manager Association Targets (p. 2151)

Update requires: Replacement (p. 121)

Example

The following example associates an SSM document with a specific instance. The ID of the instance is specified by the `myInstanceId` parameter.

JSON

```
"association": {
  "Type": "AWS::SSM::Association",
  "Properties": {
    "Name": {
      "Ref": "document"
    },
    "Parameters": {
      "Directory": ["myWorkSpace"]
    },
    "Targets": [{
      "Key": "InstanceIds",
      "Values": [{
        "Ref": "myInstanceId"
      }]
    }]
  }
}
```

YAML

```
association:
  Type: AWS::SSM::Association
  Properties:
    Name: !Ref 'document'
    Parameters:
      Directory: [FakeDirectory]
    Targets:
    - Key: InstanceIds
      Values: [!Ref 'myInstanceId']
```

AWS Systems Manager Association InstanceAssociationOutputLocation

`InstanceAssociationOutputLocation` is a property of the AWS::SSM::Association (p. 2148) resource that specifies an Amazon S3 bucket where you want to store the results of this association request.

Syntax

JSON

```
{
  "S3Location" : S3OutputLocation (p. 2151)
}
```

YAML

```
S3Location: S3OutputLocation (p. 2151)
```

Properties

`S3Location`

An Amazon S3 bucket where you want to store the results of this request.

Required: No

Type: S3OutputLocation (p. 2151)

Update requires: No interruption (p. 120)

AWS Systems Manager Association S3OutputLocation

`S3OutputLocation` is a property of the InstanceAssociationOutputLocation (p. 2150) property that specifies an Amazon S3 bucket where you want to store the results of this request.

Syntax

JSON

```
{
  "OutputS3BucketName" : String,
  "OutputS3KeyPrefix" : String
}
```

YAML

```
OutputS3BucketName: String
OutputS3KeyPrefix: String
```

Properties

`OutputS3BucketName`

The name of the Amazon S3 bucket.

Minimum length of 3. Maximum length of 63.

Required: No

Type: String

Update requires: No interruption (p. 120)

`OutputS3KeyPrefix`

The Amazon S3 bucket subfolder.

Maximum length of 500.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Systems Manager Association Targets

`Targets` is a property of the AWS::SSM::Association (p. 2148) resource that specifies the targets for an SSM document in Systems Manager.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
```

```
  "Key" : String,
  "Values" : [ String, ... ]
}
```

YAML

```
Key: String
Values:
  - String
```

Properties

`Key`

The name of the criteria that EC2 instances must meet. For valid keys, see the Target data type in the *AWS Systems Manager API Reference*.

Required: Yes

Type: String

`Values`

The value of the criteria. Systems Manager runs targeted commands on EC2 instances that match the criteria. For more information, see the Target data type in the *AWS Systems Manager API Reference*.

Required: Yes

Type: List of String values

AWS::SSM::Document

The `AWS::SSM::Document` resource creates an SSM document in AWS Systems Manager that describes an instance configuration, which you can use to set up and run commands on your instances.

Topics

- Syntax (p. 2152)
- Properties (p. 2153)
- Return Value (p. 2153)
- Examples (p. 2154)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SSM::Document",
  "Properties" : {
    "Content" : JSON object,
    "DocumentType" : String,
    "Tags" : [ Resource Tag, ... ]
  }
```

```
}
```

YAML

```
Type: "AWS::SSM::Document"
Properties:
  Content: JSON object
  DocumentType: String
  Tags:
    - Resource Tag
```

Properties

`Content`

A JSON object that describes an instance configuration. For more information, see Creating Systems Manager Documents in the *AWS Systems Manager User Guide*.

> **Note**
> The `Content` property is a non-stringified property. For more information about automation actions, see Systems Manager Automation Document Reference in the *AWS Systems Manager User Guide*.

Required: Yes

Type: JSON object

Update requires: Replacement (p. 121)

`DocumentType`

The type of document to create that relates to the purpose of your document, such as running commands, bootstrapping software, or automating tasks. For valid values, see the CreateDocument action in the *AWS Systems Manager API Reference*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Tags`

AWS CloudFormation resource tags to apply to the document, which can help you identify and categorize these resources.

Required: No

Type: Resource Tag (p. 2258)

Update requires: No interruption (p. 120)

Return Value

Ref

When you pass the logical ID of an `AWS::SSM::Document` resource to the intrinsic `Ref` function, the function returns the Systems Manager document name, such as `ssm-myinstanceconfig-ABCNPH3XCAO6`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following Systems Manager document joins instances to a directory in AWS Directory Service. The three runtime configuration parameters specify which directory the instance joins. You specify these parameter values when you associate the document with an instance.

JSON

```
"document" : {
  "Type" : "AWS::SSM::Document",
  "Properties" : {
    "Content" : {
      "schemaVersion":"1.2",
      "description":"Join instances to an AWS Directory Service domain.",
      "parameters":{
        "directoryId":{
          "type":"String",
          "description":"(Required) The ID of the AWS Directory Service directory."
        },
        "directoryName":{
          "type":"String",
          "description":"(Required) The name of the directory; for example,
 test.example.com"
        },
        "dnsIpAddresses":{
          "type":"StringList",
          "default":[
          ],
          "description":"(Optional) The IP addresses of the DNS servers in the directory.
 Required when DHCP is not configured. Learn more at http://docs.aws.amazon.com/
directoryservice/latest/simple-ad/join_get_dns_addresses.html",
          "allowedPattern":"((25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?)\\.){3}(25[0-5]|2[0-4]
[0-9]|[01]?[0-9][0-9]?)"
        }
      },
      "runtimeConfig":{
        "aws:domainJoin":{
          "properties":{
            "directoryId":"{{ directoryId }}",
            "directoryName":"{{ directoryName }}",
            "dnsIpAddresses":"{{ dnsIpAddresses }}"
          }
        }
      }
    }
  }
}
```

YAML

```
document:
  Type: "AWS::SSM::Document"
  Properties:
    Content:
      schemaVersion: "1.2"
      description: "Join instances to an AWS Directory Service domain."
      parameters:
        directoryId:
          type: "String"
          description: "(Required) The ID of the AWS Directory Service directory."
```

```
        directoryName:
          type: "String"
          description: "(Required) The name of the directory; for example,
 test.example.com"
        dnsIpAddresses:
          type: "StringList"
          default: []
          description: "(Optional) The IP addresses of the DNS servers in the directory.
 Required when DHCP is not configured. Learn more at http://docs.aws.amazon.com/
directoryservice/latest/simple-ad/join_get_dns_addresses.html"
          allowedPattern: "((25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?)\\.){3}(25[0-5]|2[0-4]
[0-9]|[01]?[0-9][0-9]?)"
      runtimeConfig:
        aws:domainJoin:
          properties:
            directoryId: "{{ directoryId }}"
            directoryName: "{{ directoryName }}"
            dnsIpAddresses: "{{ dnsIpAddresses }}"
```

The following example shows how to associate the SSM document with an instance. The `DocumentName` property specifies the SSM document and the `AssociationParameters` property specifies values for the runtime configuration parameters.

JSON

```
"myEC2" : {
  "Type" : "AWS::EC2::Instance",
  "Properties" : {
    "ImageId" : {"Ref" : "myImageId"},
    "InstanceType" : "t2.micro",
    "SsmAssociations" : [ {
      "DocumentName" : {"Ref" : "document"},
      "AssociationParameters" : [
        { "Key" : "directoryId", "Value" : [ { "Ref" : "myDirectory" } ] },
        { "Key" : "directoryName", "Value" : ["testDirectory.example.com"] },
        { "Key" : "dnsIpAddresses", "Value" : { "Fn::GetAtt" : ["myDirectory",
 "DnsIpAddresses"] } }
      ]
    } ],
    "IamInstanceProfile" : {"Ref" : "myInstanceProfile"},
    "NetworkInterfaces" : [ {
      "DeviceIndex" : "0",
      "AssociatePublicIpAddress" : "true",
      "SubnetId" : {"Ref" : "mySubnet"}
    } ],
    "KeyName" : {"Ref" : "myKeyName"}
  }
}
```

YAML

```
myEC2:
  Type: "AWS::EC2::Instance"
  Properties:
    ImageId:
      Ref: "myImageId"
    InstanceType: "t2.micro"
    SsmAssociations:
      -
        DocumentName:
          Ref: "document"
        AssociationParameters:
```

```
          -
            Key: "directoryId"
            Value:
              -
                Ref: "myDirectory"
          -
            Key: "directoryName"
            Value:
              - "testDirectory.example.com"
          -
            Key: "dnsIpAddresses"
            Value:
              Fn::GetAtt:
                - "myDirectory"
                - "DnsIpAddresses"
    IamInstanceProfile:
      Ref: "myInstanceProfile"
    NetworkInterfaces:

        DeviceIndex: "0"
        AssociatePublicIpAddress: "true"
        SubnetId:
          Ref: "mySubnet"
    KeyName:
      Ref: "myKeyName"
```

AWS::SSM::MaintenanceWindow

The `AWS::SSM::MaintenanceWindow` resource represents general information about a Maintenance Window for AWS Systems Manager. Maintenance Windows let you define a schedule for when to perform potentially disruptive actions on your instances—such as patching an operating system (OS), updating drivers, or installing software. Each Maintenance Window has a schedule, a duration, a set of registered targets, and a set of registered tasks. For more information, see Systems Manager Maintenance Windows in the *AWS Systems Manager User Guide* and CreateMaintenanceWindow in the *AWS Systems Manager API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SSM::MaintenanceWindow",
  "Properties" : {
    "Name" : String,
    "Description" : String,
    "AllowUnassociatedTargets" : Boolean,
    "Schedule" : String,
    "Duration" : Integer,
    "Cutoff" : Integer,
    "StartDate" : String,,
    "EndDate" : String,,
    "ScheduleTimezone" : String
  }
}
```

YAML

```
Type: "AWS::SSM::MaintenanceWindow"
Properties:
```

```
  Name: String
  Description: String
  AllowUnassociatedTargets: Boolean
  Schedule: String
  Duration: Integer
  Cutoff: Integer
  StartDate: String
  EndDate: String
  ScheduleTimezone: String
```

Properties

`Name`

The name of the Maintenance Window.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Description`

A description of the Maintenance Window.

Required: No

Type: String

Update requires: No interruption (p. 120)

`AllowUnassociatedTargets`

Enables a Maintenance Window task to execute on managed instances, even if you haven't registered those instances as targets. If this is enabled, then you must specify the unregistered instances (by instance ID) when you register a task with the Maintenance Window.

Required: Yes

Type: Boolean

Update requires: No interruption (p. 120)

`Schedule`

The schedule of the Maintenance Window in the form of a cron or rate expression.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Duration`

The duration of the Maintenance Window in hours.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

`Cutoff`

The number of hours before the end of the Maintenance Window that Systems Manager stops scheduling new tasks for execution.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

`StartDate`

The date and time, in ISO-8601 Extended format, for when you want the Maintenance Window to become active. StartDate allows you to delay activation of the Maintenance Window until the specified future date.

Required: No

Type: String

Update requires: No interruption (p. 120)

`EndDate`

The date and time, in ISO-8601 Extended format, for when you want the Maintenance Window to become inactive. EndDate allows you to set a date and time in the future when the Maintenance Window will no longer run.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ScheduleTimezone`

The time zone that the scheduled Maintenance Window executions are based on, in Internet Assigned Numbers Authority (IANA) format. For example: "America/Los_Angeles", "etc/UTC", or "Asia/Seoul". For more information, see the Time Zone Database on the IANA website.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::SSM::MaintenanceWindow` resource to the intrinsic `Ref` function, the function returns the maintenance window ID, such as `mw-abcde1234567890yz`.

For more information about using the `Ref` function, see Ref (p. 2341).

See Also

- AWS::SSM::MaintenanceWindowTarget (p. 2159)
- AWS::SSM::MaintenanceWindowTask (p. 2161)
- CreateMaintenanceWindow in the *AWS Systems Manager API Reference*

AWS::SSM::MaintenanceWindowTarget

The `AWS::SSM::MaintenanceWindowTarget` resource registers a target with a Maintenance Window for AWS Systems Manager. For more information, see RegisterTargetWithMaintenanceWindow in the *AWS Systems Manager API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SSM::MaintenanceWindowTarget",
  "Properties" : {
    "OwnerInformation" : String,
    "Description" : String,
    "WindowId" : String,
    "ResourceType" : String,
    "Targets" : [ Targets (p. 2161), ... ],
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::SSM::MaintenanceWindowTarget"
Properties:
  OwnerInformation: String
  Description: String
  WindowId: String
  ResourceType: String
  Targets:
    - Targets (p. 2161)
  Name: String
```

Properties

`OwnerInformation`

A user-provided value to include in any events in CloudWatch Events that are raised while running tasks for these targets in this Maintenance Window.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

A description for the target.

Required: No

Type: String

Update requires: No interruption (p. 120)

`WindowId`

The ID of the Maintenance Window to register the target with.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`ResourceType`

The type of target that's being registered with the Maintenance Window.

Required: Yes

Type: String

Valid values: `INSTANCE`

Update requires: No interruption (p. 120)

`Targets`

The targets, either instances or tags.

Specify instances using the following format:

`Key=InstanceIds,Values=instance-id-1,instance-id-2`

Specify tags using either of the following formats:

`Key=tag:tag-key,Values=tag-value-1,tag-value-2`

`Key=tag-key,Values=tag-key-1,tag-key-2`

Required: Yes

Type: List of Targets (p. 2161)

Update requires: No interruption (p. 120)

`Name`

An optional name for the target.

Required: No

Type: String

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::SSM::MaintenanceWindowTarget` resource to the intrinsic `Ref` function, the function returns the maintenance window target ID, such as `12a345b6-bbb7-4bb6-90b0-8c9577a2d2b9`.

For more information about using the `Ref` function, see Ref (p. 2341).

See Also

- AWS::SSM::MaintenanceWindow (p. 2156)
- AWS::SSM::MaintenanceWindowTask (p. 2161)
- RegisterTargetWithMaintenanceWindow in the *AWS Systems Manager API Reference*

AWS Systems Manager MaintenanceWindowTarget Targets

The `Targets` property type specifies adding a target to a Maintenance Window target in AWS Systems Manager.

`Targets` is a property of the AWS::SSM::MaintenanceWindowTarget (p. 2159) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Key" : String,
  "Values" : [ String, ... ]
}
```

YAML

```
Key: String
Values:
  - String
```

Properties

`Key`

User-defined criteria for sending commands that target instances that meet the criteria. `Key` can be `tag:`*`Amazon EC2 tag`* or `InstanceIds`. For more information about how to send commands that target instances using `Key,Value` parameters, see Sending Commands to a Fleet in the *AWS Systems Manager User Guide*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Values`

User-defined criteria that maps to `Key`. For example, if you specify `tag:ServerRole`, you can specify `value:WebServer` to execute a command on instances that include the Amazon EC2 tags of `ServerRole,WebServer`. For more information about how to send commands that target instances using `Key,Value` parameters, see Sending Commands to a Fleet in the *AWS Systems Manager User Guide*.

Required: No

Type: List of strings

Update requires: No interruption (p. 120)

AWS::SSM::MaintenanceWindowTask

The `AWS::SSM::MaintenanceWindowTask` resource defines information about a task for a Maintenance Window for AWS Systems Manager. For more information, see RegisterTaskWithMaintenanceWindow in the *AWS Systems Manager API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SSM::MaintenanceWindowTask",
  "Properties" : {
    "MaxErrors" : String,
    "Description" : String,
    "ServiceRoleArn" : String,
    "Priority" : Integer,
    "MaxConcurrency" : String,
    "Targets" : [ Target (p. 2172), ... ],
    "Name" : String,
    "TaskArn" : String,
    "TaskInvocationParameters" : TaskInvocationParameters (p. 2173),
    "WindowId" : String,
    "TaskParameters" : JSON object,
    "TaskType" : String,
    "LoggingInfo" : LoggingInfo (p. 2165)
  }
}
```

YAML

```
Type: "AWS::SSM::MaintenanceWindowTask"
Properties:
  MaxErrors: String
  Description: String
  ServiceRoleArn: String
  Priority: Integer
  MaxConcurrency: String
  Targets:
    - Target (p. 2172)
  Name: String
  TaskArn: String
  TaskInvocationParameters:
    TaskInvocationParameters (p. 2173)
  WindowId: String
  TaskParameters:
    JSON object
  TaskType: String
  LoggingInfo:
    LoggingInfo (p. 2165)
```

Properties

`MaxErrors`

The maximum number of errors allowed before this task stops being scheduled.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Description`

A description of the task.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ServiceRoleArn`

The role that's used when the task is executed.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Priority`

The priority of the task in the Maintenance Window. The lower the number, the higher the priority. Tasks that have the same priority are scheduled in parallel.

Required: Yes

Type: Integer

Update requires: No interruption (p. 120)

`MaxConcurrency`

The maximum number of targets that you can run this task for, in parallel.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Targets`

The targets, either instances or tags.

- Specify instances using `Key=instanceids,Values=`*`instanceid1,instanceid2`*.
- Specify tags using `Key=`*`tag name`*`,Values=`*`tag value`*.

Required: Yes

Type: List of Target (p. 2172)

Update requires: No interruption (p. 120)

`Name`

The task name.

Required: No

Type: String

Update requires: No interruption (p. 120)

`TaskArn`

The resource that the task uses during execution.

For `RUN_COMMAND` and `AUTOMATION` task types, `TaskArn` is the SSM document name or Amazon Resource Name (ARN).

For `LAMBDA` tasks, `TaskArn` is the function name or ARN.

For `STEP_FUNCTION` tasks, `TaskArn` is the state machine ARN.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`TaskInvocationParameters`

The parameters for task execution.

Required: No

Type: TaskInvocationParameters (p. 2173)

Update requires: No interruption (p. 120)

`WindowId`

The ID of the Maintenance Window where the task is registered.

Required: No

Type: String

Update requires: Replacement (p. 121)

`TaskParameters`

The parameters to pass to the task when it's executed.

> **Note**
> `TaskParameters` has been deprecated. To specify parameters to pass to a task when it runs, instead use the `Parameters` option in the `TaskInvocationParameters` structure. For information about how Systems Manager handles these options for the supported Maintenance Window task types, see AWS Systems Manager MaintenanceWindowTask TaskInvocationParameters (p. 2173).

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`TaskType`

The type of task. Valid values: `RUN_COMMAND`, `AUTOMATION`, `LAMBDA`, `STEP_FUNCTION`.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`LoggingInfo`

Information about an Amazon S3 bucket to write task-level logs to.

> **Note**
> `LoggingInfo` has been deprecated. To specify an S3 bucket to contain logs, instead use the `OutputS3BucketName` and `OutputS3KeyPrefix` options in the `TaskInvocationParameters` structure. For information about how Systems Manager handles these options for the supported Maintenance Window task types, see AWS Systems Manager MaintenanceWindowTask TaskInvocationParameters (p. 2173).

Required: No

Type: LoggingInfo (p. 2165)

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::SSM::MaintenanceWindowTask` resource to the intrinsic `Ref` function, the function returns the maintenance window task ID, such as `12a345b6-bbb7-4bb6-90b0-8c9577a2d2b9`.

For more information about using the `Ref` function, see Ref (p. 2341).

See Also

- AWS::SSM::MaintenanceWindow (p. 2156)
- AWS::SSM::MaintenanceWindowTarget (p. 2159)
- RegisterTaskWithMaintenanceWindow in the *AWS Systems Manager API Reference*

AWS Systems Manager MaintenanceWindowTask LoggingInfo

The `LoggingInfo` property type specifies information about the Amazon S3 bucket to write instance-level logs to.

`LoggingInfo` is a property of the AWS::SSM::MaintenanceWindowTask (p. 2161) resource.

> **Note**
> `LoggingInfo` has been deprecated. To specify an S3 bucket to contain logs, instead use the `OutputS3BucketName` and `OutputS3KeyPrefix` options in the `TaskInvocationParameters` structure. For information about how Systems Manager handles these options for the supported Maintenance Window task types, see AWS Systems Manager MaintenanceWindowTask TaskInvocationParameters (p. 2173).

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "S3Bucket" : String,
  "Region" : String,
  "S3Prefix" : String
}
```

YAML

```
S3Bucket: String
Region: String
S3Prefix: String
```

Properties

`S3Bucket`

The name of the Amazon S3 bucket where execution logs are stored.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Region`

The region where the Amazon S3 bucket is located.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`S3Prefix`

The Amazon S3 bucket subfolder.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Systems Manager MaintenanceWindowTask MaintenanceWindowAutomationParameters

The `MaintenanceWindowAutomationParameters` property type specifies the parameters for an `AUTOMATION` task type for a Maintenance Window task in AWS Systems Manager .

`MaintenanceWindowAutomationParameters` is a property of the TaskInvocationParameters (p. 2173) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Parameters" : JSON object,
  "DocumentVersion" : String
}
```

YAML

```
Parameters:
  JSON object
DocumentVersion: String
```

Properties

`Parameters`

The parameters for the `AUTOMATION` task.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`DocumentVersion`

The version of an Automation document to use during task execution.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Systems Manager MaintenanceWindowTask MaintenanceWindowLambdaParameters

The `MaintenanceWindowLambdaParameters` property type specifies the parameters for a `LAMBDA` task type for a Maintenance Window task in AWS Systems Manager.

`MaintenanceWindowLambdaParameters` is a property of the TaskInvocationParameters (p. 2173) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "ClientContext" : String,
  "Qualifier" : String,
  "Payload" : String
}
```

YAML

```
ClientContext: String
Qualifier: String
Payload: String
```

Properties

`ClientContext`

Client-specific information to pass to the Lambda function that you're invoking. You can then use the `context` variable to process the client information in your Lambda function.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Qualifier`

A Lambda function version or alias name. If you specify a function version, the action uses the qualified function Amazon Resource Name (ARN) to invoke a specific Lambda function. If you specify an alias name, the action uses the alias ARN to invoke the Lambda function version that the alias points to.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Payload`

JSON to provide to your Lambda function as input.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Systems Manager MaintenanceWindowTask MaintenanceWindowRunCommandParameters

The `MaintenanceWindowRunCommandParameters` property type specifies the parameters for a `RUN_COMMAND` task type for a Maintenance Window task in AWS Systems Manager.

`MaintenanceWindowRunCommandParameters` is a property of the TaskInvocationParameters (p. 2173) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "TimeoutSeconds" : Integer,
  "Comment" : String,
  "OutputS3KeyPrefix" : String,
  "Parameters" : JSON object,
  "DocumentHashType" : String,
  "ServiceRoleArn" : String,
  "NotificationConfig" : NotificationConfig (p. 2171),
  "OutputS3BucketName" : String,
  "DocumentHash" : String
}
```

YAML

```
TimeoutSeconds: Integer
Comment: String
OutputS3KeyPrefix: String
Parameters:
  JSON object
DocumentHashType: String
ServiceRoleArn: String
NotificationConfig:
  NotificationConfig (p. 2171)
OutputS3BucketName: String
DocumentHash: String
```

Properties

`TimeoutSeconds`

If this time is reached and the command hasn't already started executing, it doesn't execute.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`Comment`

Information about the command or commands to execute.

Required: No

Type: String

Update requires: No interruption (p. 120)

`OutputS3KeyPrefix`

The Amazon S3 bucket subfolder.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Parameters`

The parameters for the `RUN_COMMAND` task execution.

Required: No

Type: JSON object

Update requires: No interruption (p. 120)

`DocumentHashType`

The SHA-256 or SHA-1 hash type. SHA-1 hashes are deprecated.

Required: No

Type: String

Update requires: No interruption (p. 120)

`ServiceRoleArn`

The IAM service role that's used during task execution.

Required: No

Type: String

Update requires: No interruption (p. 120)

`NotificationConfig`

Configurations for sending notifications about command status changes on a per-instance basis.

Required: No

Type: NotificationConfig (p. 2171)

Update requires: No interruption (p. 120)

`OutputS3BucketName`

The name of the Amazon S3 bucket.

Required: No

Type: String

Update requires: No interruption (p. 120)

`DocumentHash`

The SHA-256 or SHA-1 hash created by the system when the document was created. SHA-1 hashes are deprecated.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Systems Manager MaintenanceWindowTask MaintenanceWindowStepFunctionsParameters

The `MaintenanceWindowStepFunctionsParameters` property type specifies the parameters for execution of the `STEP_FUNCTION` for a Maintenance Window task in AWS Systems Manager.

`MaintenanceWindowStepFunctionsParameters` is a property of the TaskInvocationParameters (p. 2173) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Input" : String,
  "Name" : String
}
```

YAML

```
Input: String
Name: String
```

Properties

`Input`

The inputs for the `STEP_FUNCTION` task.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the `STEP_FUNCTION` task.

Required: No

Type: String

Update requires: No interruption (p. 120)

AWS Systems Manager MaintenanceWindowTask NotificationConfig

The `NotificationConfig` property type specifies configurations for sending notifications for a Maintenance Window task in AWS Systems Manager.

`NotificationConfig` is a property of the MaintenanceWindowRunCommandParameters (p. 2168) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "NotificationArn" : String,
  "NotificationType" : String,
  "NotificationEvents" : [ String, ... ]
}
```

YAML

```
NotificationArn: String
NotificationType: String
NotificationEvents:
  - String
```

Properties

`NotificationArn`

An Amazon Resource Name (ARN) for an Amazon SNS topic. Run Command pushes notifications about command status changes to this topic.

Required: No

Type: String

Update requires: No interruption (p. 120)

`NotificationType`

The notification type.

- `Command`: Receive notification when the status of a command changes.
- `Invocation`: For commands sent to multiple instances, receive notification on a per-instance basis when the status of a command changes.

Required: No

Type: String

Update requires: No interruption (p. 120)

`NotificationEvents`

The different events that you can receive notifications for. These events include the following: `All` (events), `InProgress`, `Success`, `TimedOut`, `Cancelled`, `Failed`. To learn more about these events, see Understanding Command Statuses in the *AWS Systems Manager User Guide*.

Required: No

Type: List of strings

Update requires: No interruption (p. 120)

AWS Systems Manager MaintenanceWindowTask Target

The `Target` property type specifies targets (either instances or tags). You specify instances by using `Key=instanceids,Values=instanceid1,instanceid2`. You specify tags by using `Key=tag name,Values=tag value` for a Maintenance Window task in AWS Systems Manager.

`Target` is a property of the AWS::SSM::MaintenanceWindowTask (p. 2161) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Key" : String,
  "Values" : [ String, ... ]
}
```

YAML

```
Key: String
Values:
  - String
```

Properties

`Key`

User-defined criteria for sending commands that target instances that meet the criteria. `Key` can be `tag:Amazon EC2 tag` or `InstanceIds`. For more information about how to send commands that target instances by using `Key,Value` parameters, see Sending Commands to a Fleet in the *AWS Systems Manager User Guide*.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Values`

User-defined criteria that maps to `Key`. For example, if you specify `tag:ServerRole`, you can specify `value:WebServer` to execute a command on instances that include Amazon EC2 tags of `ServerRole,WebServer`. For more information about how to send commands that target instances using `Key,Value` parameters, see Sending Commands to a Fleet in the *AWS Systems Manager User Guide*.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

AWS Systems Manager MaintenanceWindowTask TaskInvocationParameters

The `TaskInvocationParameters` property type specifies the task execution parameters for a Maintenance Window task in AWS Systems Manager.

`TaskInvocationParameters` is a property of the AWS::SSM::MaintenanceWindowTask (p. 2161) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "MaintenanceWindowRunCommandParameters" : MaintenanceWindowRunCommandParameters (p. 2168),
  "MaintenanceWindowAutomationParameters" : MaintenanceWindowAutomationParameters (p. 2166),

 "MaintenanceWindowStepFunctionsParameters" : MaintenanceWindowStepFunctionsParameters (p. 2170),
  "MaintenanceWindowLambdaParameters" : MaintenanceWindowLambdaParameters (p. 2167)
}
```

YAML

```
MaintenanceWindowRunCommandParameters:
  MaintenanceWindowRunCommandParameters (p. 2168)
MaintenanceWindowAutomationParameters:
  MaintenanceWindowAutomationParameters (p. 2166)
MaintenanceWindowStepFunctionsParameters:
  MaintenanceWindowStepFunctionsParameters (p. 2170)
MaintenanceWindowLambdaParameters:
  MaintenanceWindowLambdaParameters (p. 2167)
```

Properties

`MaintenanceWindowRunCommandParameters`

The parameters for a `RUN_COMMAND` task type.

Required: No

Type: MaintenanceWindowRunCommandParameters (p. 2168)

Update requires: No interruption (p. 120)

`MaintenanceWindowAutomationParameters`

The parameters for an `AUTOMATION` task type.

Required: No

Type: MaintenanceWindowAutomationParameters (p. 2166)

Update requires: No interruption (p. 120)

`MaintenanceWindowStepFunctionsParameters`

The parameters for a `STEP_FUNCTION` task type.

Required: No

Type: MaintenanceWindowStepFunctionsParameters (p. 2170)

Update requires: No interruption (p. 120)

`MaintenanceWindowLambdaParameters`

The parameters for a `LAMBDA` task type.

Required: No

Type: MaintenanceWindowLambdaParameters (p. 2167)

Update requires: No interruption (p. 120)

AWS::SSM::Parameter

The `AWS::SSM::Parameter` resource creates an SSM parameter in AWS Systems Manager Parameter Store.

For information about valid values for parameters, see Requirements and Constraints for Parameter Names in the *AWS Systems Manager User Guide* and PutParameter in the *AWS Systems Manager API Reference*.

Topics

- Syntax (p. 2174)
- Properties (p. 2175)
- Return Value (p. 2176)
- Examples (p. 2176)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SSM::Parameter",
  "Properties" : {
    "AllowedPattern" : String,
    "Description" : String,
    "Name" : String,
    "Type" : String,
    "Value" : String
  }
}
```

YAML

```
Type: "AWS::SSM::Parameter"
Properties:
```

```
  AllowedPattern: String
  Description: String
  Name: String
  Type: String
  Value: String
```

Properties

`AllowedPattern`

A regular expression used to validate the parameter value. For example, for String types with values restricted to numbers, you can specify the following: `AllowedPattern=^\d+$`

Required: No

Type: String

Update requires: No interruption (p. 120)

`Description`

Information about the parameter that you want to add to the system.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Name`

The name of the parameter.

For information about valid values for parameter names, see Requirements and Constraints for Parameter Names in the *AWS Systems Manager User Guide*.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Type`

The type of parameter. Valid values include the following: `String` or `StringList`.

> **Note**
> AWS CloudFormation doesn't support the `SecureString` parameter type.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`Value`

The parameter value. Value must not nest another parameter. Do not use `{{}}` in the value.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

Return Value

Ref

When you pass the logical ID of an `AWS::SSM::Parameter` resource to the intrinsic `Ref` function, the function returns the Name of the SSM parameter. For example, `ssm-myparameter-ABCNPH3XCAO6`.

For more information about using the `Ref` function, see Ref (p. 2341).

Fn::GetAtt

`Fn::GetAtt` returns a value for a specified attribute of this type. The following are the available attributes and sample return values.

`Type`

Returns the type of the parameter. Valid values are `String` or `StringList`.

`Value`

Returns the value of the parameter.

For more information about using `Fn::GetAtt`, see Fn::GetAtt (p. 2313).

Examples

SSM Parameter (String) Example

The following example snippet creates an SSM parameter in Parameter Store.

JSON

```
{
   "Description": "Create SSM Parameter",
   "Resources": {
      "BasicParameter": {
         "Type": "AWS::SSM::Parameter",
         "Properties": {
            "Name": "command",
            "Type": "String",
            "Value": "date",
            "Description": "SSM Parameter for running date command.",
            "AllowedPattern" : "^[a-zA-Z]{1,10}$"
         }
      }
   }
}
```

YAML

```
Description: "Create SSM Parameter"
Resources:
  BasicParameter:
    Type: "AWS::SSM::Parameter"
    Properties:
      Name: "command"
      Type: "String"
      Value: "date"
      Description: "SSM Parameter for running date command."
      AllowedPattern: "^[a-zA-Z]{1,10}$"
```

SSM Parameter (StringList) Example

The following example creates an SSM parameter with a `StringList` type.

JSON

```
{
   "Description": "Create SSM Parameter",
   "Resources": {
      "BasicParameter": {
         "Type": "AWS::SSM::Parameter",
         "Properties": {
            "Name": "commands",
            "Type": "StringList",
            "Value": "date,ls",
            "Description": "SSM Parameter of type StringList.",
            "AllowedPattern" : "^[a-zA-Z]{1,10}$"
         }
      }
   }
}
```

YAML

```
Description: "Create SSM Parameter"
Resources:
  BasicParameter:
    Type: "AWS::SSM::Parameter"
    Properties:
      Name: "commands"
      Type: "StringList"
      Value: "date,ls"
      Description: "SSM Parameter of type StringList."
      AllowedPattern: "^[a-zA-Z]{1,10}$"
```

AWS::SSM::PatchBaseline

The `AWS::SSM::PatchBaseline` resource defines the basic information for an AWS Systems Manager patch baseline. A patch baseline defines which patches are approved for installation on your instances. For more information, see CreatePatchBaseline in the *AWS Systems Manager API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SSM::PatchBaseline",
  "Properties" : {
    "Name" : String,
    "OperatingSystem" : String,
    "Description" : String,
    "PatchGroups" : [ String, ... ],
    "ApprovalRules" : RuleGroup (p. 2184),
    "ApprovedPatches" : [ String, ... ],
    "ApprovedPatchesComplianceLevel" : String,
    "ApprovedPatchesEnableNonSecurity" : Boolean,
    "RejectedPatches" : [ String, ... ],
    "RejectedPatchesAction" : [ String ],
    "GlobalFilters" : PatchFilterGroup (p. 2181),
```

```
    "Sources" : PatchSource (p. 2182)
  }
}
```

YAML

```
Type: "AWS::SSM::PatchBaseline"
Properties:
  Name: String
  OperatingSystem: String
  Description: String
  PatchGroups:
    - String
  ApprovalRules:
    RuleGroup (p. 2184)
  ApprovedPatches:
    - String
  ApprovedPatchesComplianceLevel: String
  ApprovedPatchesEnableNonSecurity : Boolean
  RejectedPatches:
    - String
  RejectedPatchesAction :
    - String
  GlobalFilters:
    PatchFilterGroup (p. 2181)
  Sources : PatchSource (p. 2182)
```

Properties

`Name`

The name of the patch baseline.

Required: Yes

Type: String

Update requires: No interruption (p. 120)

`OperatingSystem`

Defines the operating system that the patch baseline applies to. Supported operating systems include `WINDOWS`, `AMAZON_LINUX`, `AMAZON_LINUX_2`, `UBUNTU`, `REDHAT_ENTERPRISE_LINUX`, `SUSE`, and `CENTOS`. The default value is `WINDOWS`.

Required: No

Type: String

Update requires: Replacement (p. 121)

`Description`

A description of the patch baseline.

Required: No

Type: String

Update requires: No interruption (p. 120)

`PatchGroups`

The names of the patch groups to register with the patch baseline.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`ApprovalRules`

A set of rules that are used to include patches in the baseline.

Required: No

Type: RuleGroup (p. 2184)

Update requires: No interruption (p. 120)

`ApprovedPatches`

A list of explicitly approved patches for the baseline.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`ApprovedPatchesComplianceLevel`

The compliance level for approved patches. This means that if an approved patch is reported as missing, this is the severity of the compliance violation. Valid compliance severity levels include the following: `CRITICAL`, `HIGH`, `MEDIUM`, `LOW`, `INFORMATIONAL`, and `UNSPECIFIED`. The default value is `UNSPECIFIED`.

Required: No

Type: String

Update requires: No interruption (p. 120)

ApprovedPatchesEnableNonSecurity

Indicates whether the list of approved patches includes non-security updates that should be applied to the instances. The default value is 'false'. Applies to Linux instances only.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

`RejectedPatches`

A list of explicitly rejected patches for the baseline.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

RejectedPatchesAction

The action for Patch Manager to take on patches included in the RejectedPackages list.

- **ALLOW_AS_DEPENDENCY**: A package in the Rejected patches list is installed only if it is a dependency of another package. It is considered compliant with the patch baseline, and its status is reported as *InstalledOther*. This is the default action if no option is specified.

- **BLOCK**: Packages in the RejectedPatches list, and packages that include them as dependencies, are not installed under any circumstances. If a package was installed before it was added to the Rejected patches list, it is considered non-compliant with the patch baseline, and its status is reported as *InstalledRejected*.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

`GlobalFilters`

A set of global filters that are used to exclude patches from the baseline.

Required: No

Type: PatchFilterGroup (p. 2181)

Update requires: No interruption (p. 120)

Sources

Information about the patches to use to update the instances, including target operating systems and source repositories. Applies to Linux instances only.

Required: No

Type: Array of PatchSource (p. 2182) objects

Update requires: No interruption (p. 120)

Return Values

Ref

When you pass the logical ID of an `AWS::SSM::PatchBaseline` resource to the intrinsic `Ref` function, the function returns the physical ID of the resource, such as `pb-abcde1234567890yz`.

> **Note**
> The ID of the default patch baseline provided by AWS is an ARN—for example `arn:aws:ssm:us-west-2:123456789012:patchbaseline/abcde1234567890yz`.

For more information about using the `Ref` function, see Ref (p. 2341).

- CreatePatchBaseline in the *AWS Systems Manager API Reference*

AWS Systems Manager PatchBaseline PatchFilter

The `PatchFilter` property type defines a patch filter for an AWS Systems Manager patch baseline.

The `PatchFilters` property of the PatchFilterGroup (p. 2181) property type contains a list of `PatchFilter` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Key" : String,
  "Values" : [ String, ... ]
}
```

YAML

```
Key: String
Values:
  - String
```

Properties

`Key`

The key for the filter. For information about valid keys, see PatchFilter in the *AWS Systems Manager API Reference*.

Required: No

Type: String

Update requires: No interruption (p. 120)

`Values`

The values for the filter key.

Required: No

Type: List of String values

Update requires: No interruption (p. 120)

AWS Systems Manager PatchBaseline PatchFilterGroup

The `PatchFilterGroup` property type specifies a set of patch filters for an AWS Systems Manager patch baseline, typically used for approval rules for a Systems Manager patch baseline.

`PatchFilterGroup` is the property type for the `GlobalFilters` property of the AWS::SSM::PatchBaseline (p. 2177) resource and the `PatchFilterGroup` property of the Rule (p. 2183) property type.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "PatchFilters" : [ PatchFilter (p. 2180), ... ]
}
```

YAML

```
PatchFilters:
```

```
  - PatchFilter (p. 2180)
```

Properties

`PatchFilters`

The set of patch filters that make up the group.

Required: No

Type: List of PatchFilter (p. 2180)

Update requires: No interruption (p. 120)

PatchSource

`PatchSource` is the property type for the `Sources` resource of the AWS::SSM::PatchBaseline (p. 2177) resource.

The AWS CloudFormation `AWS::SSM::PatchSource` resource is used to provide information about the patches to use to update target instances, including target operating systems and source repository. Applies to Linux instances only.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Configuration" : String,
  "Name" : String,
  "Products" : { String:String, ... }
}
```

YAML

```
Configuration: String
Name: String
Products: String: String
```

Properties

`Configuration`

The value of the yum repo configuration.

Required: Yes

Type: String

`Name`

The name specified to identify the patch source.

Required: No

Type: String

`Products`

The specific operating system versions a patch repository applies to, such as "Ubuntu16.04", "AmazonLinux2016.09", "RedhatEnterpriseLinux7.2" or "Suse12.7". For lists of supported product values, see PatchFilter in the *AWS Systems Manager API Reference*.

Required: Yes

Type: String to String map

AWS Systems Manager PatchBaseline Rule

The `Rule` property type specifies an approval rule for a Systems Manager patch baseline.

The `PatchRules` property of the RuleGroup (p. 2184) property type contains a list of `Rule` property types.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "PatchFilterGroup" : PatchFilterGroup (p. 2181),
  "ApproveAfterDays" : Integer,
  "ComplianceLevel" : String,
  "EnableNonSecurity" : Boolean
}
```

YAML

```
PatchFilterGroup:
  PatchFilterGroup (p. 2181)
ApproveAfterDays: Integer
ComplianceLevel: String
EnableNonSecurity: Boolean
```

Properties

`PatchFilterGroup`

The patch filter group that defines the criteria for the rule.

Required: No

Type: PatchFilterGroup (p. 2181)

Update requires: No interruption (p. 120)

`ApproveAfterDays`

The number of days after the release date of each patch matched by the rule that the patch is marked as approved in the patch baseline. For example, a value of `7` means that patches are approved seven days after they are released.

Required: No

Type: Integer

Update requires: No interruption (p. 120)

`ComplianceLevel`

A compliance severity level for all approved patches in a patch baseline. Valid compliance severity levels include the following: `UNSPECIFIED`, `CRITICAL`, `HIGH`, `MEDIUM`, `LOW`, and `INFORMATIONAL`.

Required: No

Type: String

Update requires: No interruption (p. 120)

`EnableNonSecurity`

For instances identified by the approval rule filters, enables a patch baseline to apply non-security updates available in the specified repository. The default value is `false`. Applies to Linux instances only.

Required: No

Type: Boolean

Update requires: No interruption (p. 120)

See Also

- PatchRule in the *AWS Systems Manager API Reference*.

AWS Systems Manager PatchBaseline RuleGroup

The `RuleGroup` property type specifies a set of rules that define the approval rules for a AWS Systems Manager patch baseline.

`RuleGroup` is the property type for the `ApprovalRules` property of the AWS::SSM::PatchBaseline (p. 2177) resource.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "PatchRules" : [ Rule (p. 2183), ... ]
}
```

YAML

```
PatchRules:
  - Rule (p. 2183)
```

Properties

`PatchRules`

The rules that make up the rule group.

Required: No

Type: List of Rule (p. 2183)

Update requires: No interruption (p. 120)

AWS::SSM::ResourceDataSync

The `AWS::SSM::ResourceDataSync` resource creates or deletes a Resource Data Sync for Systems Manager Inventory. You can use Resource Data Sync to send Inventory data collected from all of your Systems Manager managed instances to a single Amazon S3 bucket that you have already created in your account. Resource Data Sync then automatically updates the centralized data when new Inventory data is collected. For more information, see Configuring Resource Data Sync for Inventory in the *AWS Systems Manager User Guide*.

Topics

- Syntax (p. 2185)
- Properties (p. 2185)
- Return Values (p. 2186)
- Examples (p. 2187)
- See Also (p. 2187)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::SSM::ResourceDataSync",
  "Properties" : {
    "KMSKeyArn" : String,
    "BucketName" : String,
    "BucketRegion" : String,
    "SyncFormat" : String,
    "SyncName" : String,
    "BucketPrefix" : String
  }
}
```

YAML

```
Type: "AWS::SSM::ResourceDataSync"
Properties:
  KMSKeyArn: String
  BucketName: String
  BucketRegion: String
  SyncFormat: String
  SyncName: String
  BucketPrefix: String
```

Properties

`KMSKeyArn`

The ARN of an encryption key for a destination in Amazon S3. You can use a KMS key to encrypt inventory data in Amazon S3. You must specify a key that exist in the same region as the destination Amazon S3 bucket.

Required: No

Type: String

Update requires: Replacement (p. 121)

`BucketName`

The name of the Amazon S3 bucket where the aggregated data is stored.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`BucketRegion`

The AWS Region with the Amazon S3 bucket targeted by the Resource Data Sync.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SyncFormat`

The format in which Resource Data Sync output will be stored in Amazon S3. The following format is currently supported: JsonSerDe

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SyncName`

A name for the Resource Data Sync.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`BucketPrefix`

An Amazon S3 prefix for the bucket.

Required: No

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When you pass the logical ID of an `AWS::SSM::ResourceDataSync` resource to the intrinsic `Ref` function, the function returns the name of the Resource Data Sync, such as `TestResourceDataSync`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

AWS Systems Manager Resource Data Sync

The following examples send Inventory data collected from all of your managed instances in the US East (Ohio) Region (us-east-2) to a single Amazon S3 bucket. Resource Data Sync then automatically updates the centralized data when new Inventory data is collected.

JSON

```
{
  "Description": "Create a Resource Data Sync for Systems Manager Inventory",
  "Resources": {
    "BasicResourceDataSync": {
      "Type": "AWS::SSM::ResourceDataSync",
      "Properties": {
        "SyncName": "My-USEAST2-Resource-Data-Sync",
        "BucketName": "my-us-east-2-rds-bucket",
        "BucketRegion": "us-east-2",
        "SyncFormat": "JsonSerDe",
        "BucketPrefix": "rds"
      }
    }
  }
}
```

YAML

```
---
Description: "Create a Resource Data Sync for Systems Manager Inventory"
Resources:
  BasicResourceDataSync:
    Type: "AWS::SSM::ResourceDataSync"
    Properties:
      SyncName: "My-USEAST2-Resource-Data-Sync"
      BucketName: "my-us-east-2-rds-bucket"
      BucketRegion: "us-east-2"
      SyncFormat: "JsonSerDe"
      BucketPrefix: "rds"
```

AWS WAF Resource Types Reference

This section contains reference information for all AWS WAF resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::WAF::data-type-name
```

Topics

- AWS::WAF::ByteMatchSet (p. 2188)
- AWS::WAF::IPSet (p. 2193)
- AWS::WAF::Rule (p. 2197)
- AWS::WAF::SizeConstraintSet (p. 2200)
- AWS::WAF::SqlInjectionMatchSet (p. 2205)
- AWS::WAF::WebACL (p. 2209)
- AWS::WAF::XssMatchSet (p. 2215)

AWS::WAF::ByteMatchSet

The `AWS::WAF::ByteMatchSet` resource creates an AWS WAF `ByteMatchSet` that identifies a part of a web request that you want to inspect. For more information, see CreateByteMatchSet in the *AWS WAF API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAF::ByteMatchSet",
  "Properties" : {
    "ByteMatchTuples" : [ Byte match tuple, ... ],
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::WAF::ByteMatchSet"
Properties:
  ByteMatchTuples:
    - Byte match tuple
  Name: String
```

Properties

`ByteMatchTuples`

Settings for the `ByteMatchSet`, such as the bytes (typically a string that corresponds with ASCII characters) that you want AWS WAF to search for in web requests.

Required: No

Type: List of AWS WAF ByteMatchSet ByteMatchTuples (p. 2191)

Update requires: No interruption (p. 120)

`Name`

A friendly name or description of the `ByteMatchSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

HTTP Referers

The following example defines a set of HTTP referers to match.

JSON

```
"BadReferers": {
  "Type": "AWS::WAF::ByteMatchSet",
  "Properties": {
    "Name": "ByteMatch for matching bad HTTP referers",
    "ByteMatchTuples": [
      {
        "FieldToMatch" : {
          "Type": "HEADER",
          "Data": "referer"
        },
        "TargetString" : "badrefer1",
        "TextTransformation" : "NONE",
        "PositionalConstraint" : "CONTAINS"
      },
      {
        "FieldToMatch" : {
          "Type": "HEADER",
          "Data": "referer"
        },
        "TargetString" : "badrefer2",
        "TextTransformation" : "NONE",
        "PositionalConstraint" : "CONTAINS"
      }
    ]
  }
}
```

YAML

```
BadReferers:
  Type: "AWS::WAF::ByteMatchSet"
  Properties:
    Name: "ByteMatch for matching bad HTTP referers"
    ByteMatchTuples:
      -
        FieldToMatch:
          Type: "HEADER"
          Data: "referer"
        TargetString: "badrefer1"
        TextTransformation: "NONE"
        PositionalConstraint: "CONTAINS"
      -
```

```
        FieldToMatch:
          Type: "HEADER"
          Data: "referer"
        TargetString: "badrefer2"
        TextTransformation: "NONE"
        PositionalConstraint: "CONTAINS"
```

Associate a ByteMatchSet with a Web ACL Rule

The following example associates the `BadReferers` byte match set with a web access control list (ACL) rule.

JSON

```
"BadReferersRule" : {
  "Type": "AWS::WAF::Rule",
  "Properties": {
    "Name": "BadReferersRule",
    "MetricName" : "BadReferersRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "BadReferers" },
        "Negated" : false,
        "Type" : "ByteMatch"
      }
    ]
  }
}
```

YAML

```
BadReferersRule:
  Type: "AWS::WAF::Rule"
  Properties:
    Name: "BadReferersRule"
    MetricName: "BadReferersRule"
    Predicates:
      -
        DataId:
          Ref: "BadReferers"
        Negated: false
        Type: "ByteMatch"
```

Create a Web ACL

The following example associates the `BadReferersRule` rule with a web ACL. The web ACL allows all requests except for ones with referers that match the `BadReferersRule` rule.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAF::WebACL",
  "Properties": {
    "Name": "WebACL to block blacklisted IP addresses",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "MyWebACL",
    "Rules": [
      {
        "Action" : {
```

```
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "BadReferersRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAF::WebACL"
  Properties:
    Name: "WebACL to block blacklisted IP addresses"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "MyWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "BadReferersRule"
```

AWS WAF ByteMatchSet ByteMatchTuples

`ByteMatchTuples` is a property of the AWS::WAF::ByteMatchSet (p. 2188) resource that specifies settings for an AWS WAF `ByteMatchSet` resource, such as the bytes (typically a string that corresponds with ASCII characters) that you want AWS WAF to search for in web requests.

Syntax

JSON

```
{
  "FieldToMatch" : Field to match,
  "PositionalConstraint" : String,
  "TargetString" : String,
  "TargetStringBase64" : String,
  "TextTransformation" : String
}
```

YAML

```
FieldToMatch:
  Field to match
PositionalConstraint: String
TargetString: String
TargetStringBase64: String
TextTransformation: String
```

Properties

`FieldToMatch`

The part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Required: Yes

Type: AWS WAF ByteMatchSet ByteMatchTuples FieldToMatch (p. 2193)

`PositionalConstraint`

How AWS WAF finds matches within the web request part in which you are searching. For valid values, see the `PositionalConstraint` content for the ByteMatchTuple data type in the *AWS WAF API Reference*.

Required: Yes

Type: String

`TargetString`

The value that AWS WAF searches for. AWS CloudFormation base64 encodes this value before sending it to AWS WAF.

AWS WAF searches for this value in a specific part of web requests, which you define in the `FieldToMatch` property.

Valid values depend on the `Type` value in the `FieldToMatch` property. For example, for a `METHOD` type, you must specify HTTP methods such as `DELETE, GET, HEAD, OPTIONS, PATCH, POST,` and `PUT`. For more information, see the `TargetString` content for the ByteMatchTuple data type in the *AWS WAF API Reference*.

Required: Conditional. You must specify this property or the `TargetStringBase64` property.

Type: String

`TargetStringBase64`

The base64-encoded value that AWS WAF searches for. AWS CloudFormation sends this value to AWS WAF without encoding it.

AWS WAF searches for this value in a specific part of web requests, which you define in the `FieldToMatch` property.

Valid values depend on the `Type` value in the `FieldToMatch` property. For example, for a `METHOD` type, you must specify HTTP methods such as `DELETE, GET, HEAD, OPTIONS, PATCH, POST,` and `PUT`. For more information, see the `TargetString` content for the ByteMatchTuple data type in the *AWS WAF API Reference*.

Required: Conditional. You must specify this property or the `TargetString` property.

Type: String

`TextTransformation`

Specifies how AWS WAF processes the target string value. Text transformations eliminate some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF. If you specify a transformation, AWS WAF transforms the target string value before inspecting a web request for a match.

For example, AWS WAF can replace whitespace characters (such as `\t` and `\n`) with a single space. For valid values, see the `TextTransformation` content for the ByteMatchTuple data type in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS WAF ByteMatchSet ByteMatchTuples FieldToMatch

`FieldToMatch` is a property of the AWS WAF ByteMatchSet ByteMatchTuples (p. 2191) property that specifies the part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Syntax

JSON

```
{
  "Data" : String,
  "Type" : String
}
```

YAML

```
Data: String
Type: String
```

Properties

`Data`

If you specify `HEADER` for the `Type` property, the name of the header that AWS WAF searches for, such as `User-Agent` or `Referer`. If you specify any other value for the `Type` property, do not specify this property.

Required: Conditional

Type: String

`Type`

The part of the web request in which AWS WAF searches for the target string. For valid values, see FieldToMatch in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS::WAF::IPSet

The `AWS::WAF::IPSet` resource creates an AWS WAF `IPSet` that specifies which web requests to permit or block based on the IP addresses from which the requests originate. For more information, see CreateIPSet in the *AWS WAF API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAF::IPSet",
  "Properties" : {
```

```
    "IPSetDescriptors" : [ IPSet descriptor, ... ],
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::WAF::IPSet"
Properties:
  IPSetDescriptors:
    - IPSet descriptor
  Name: String
```

Properties

`IPSetDescriptors`

The IP address type and IP address range (in CIDR notation) from which web requests originate. If you associate the `IPSet` with a web ACL (p. 2209) that is associated with an Amazon CloudFront (CloudFront) distribution and the viewer did not use an HTTP proxy or a load balancer to send the request, this descriptor is the value of the c-ip field in the CloudFront access logs.

Required: No

Type: List of AWS WAF IPSet IPSetDescriptors (p. 2196)

Update requires: No interruption (p. 120)

`Name`

A friendly name or description of the `IPSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Define IP Addresses

The following example defines a set of IP addresses for a web access control list (ACL) rule.

JSON

```
"MyIPSetBlacklist": {
  "Type": "AWS::WAF::IPSet",
  "Properties": {
```

```
    "Name": "IPSet for blacklisted IP adresses",
    "IPSetDescriptors": [
      {
        "Type" : "IPV4",
        "Value" : "192.0.2.44/32"
      },
      {
        "Type" : "IPV4",
        "Value" : "192.0.7.0/24"
      }
    ]
  }
}
```

YAML

```
MyIPSetBlacklist:
  Type: "AWS::WAF::IPSet"
  Properties:
    Name: "IPSet for blacklisted IP adresses"
    IPSetDescriptors:
      -
        Type: "IPV4"
        Value: "192.0.2.44/32"
      -
        Type: "IPV4"
        Value: "192.0.7.0/24"
```

Associate an IPSet with a Web ACL Rule

The following example associates the `MyIPSetBlacklist` IP Set with a web ACL rule.

JSON

```
"MyIPSetRule" : {
  "Type": "AWS::WAF::Rule",
  "Properties": {
    "Name": "MyIPSetRule",
    "MetricName" : "MyIPSetRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "MyIPSetBlacklist" },
        "Negated" : false,
        "Type" : "IPMatch"
      }
    ]
  }
}
```

YAML

```
MyIPSetRule:
  Type: "AWS::WAF::Rule"
  Properties:
    Name: "MyIPSetRule"
    MetricName: "MyIPSetRule"
    Predicates:
      -
        DataId:
          Ref: "MyIPSetBlacklist"
        Negated: false
```

```
        Type: "IPMatch"
```

Create a Web ACL

The following example associates the `MyIPSetRule` rule with a web ACL. The web ACL allows requests that originate from all IP addresses except for addresses that are defined in the `MyIPSetRule`.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAF::WebACL",
  "Properties": {
    "Name": "WebACL to block blacklisted IP addresses",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "MyWebACL",
    "Rules": [
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "MyIPSetRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAF::WebACL"
  Properties:
    Name: "WebACL to block blacklisted IP addresses"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "MyWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "MyIPSetRule"
```

AWS WAF IPSet IPSetDescriptors

`IPSetDescriptors` is a property of the AWS::WAF::IPSet (p. 2193) resource that specifies the IP address type and IP address range (in CIDR notation) from which web requests originate.

Syntax

JSON

```
{
  "Type" : String,
  "Value" : String
}
```

YAML

```
Type: String
Value: String
```

Properties

`Type`

The IP address type, such as `IPV4`. For valid values, see the `Type` contents of the IPSetDescriptor data type in the *AWS WAF API Reference*.

Required: Yes

Type: String

`Value`

An IP address (in CIDR notation) that AWS WAF permits, blocks, or counts. For example, to specify a single IP address such as `192.0.2.44`, specify `192.0.2.44/32`. To specify a range of IP addresses such as `192.0.2.0` to `192.0.2.255`, specify `192.0.2.0/24`.

Required: Yes

Type: String

AWS::WAF::Rule

The `AWS::WAF::Rule` resource creates an AWS WAF rule that specifies a combination of `IPSet`, `ByteMatchSet`, and `SqlInjectionMatchSet` objects that identify the web requests to allow, block, or count. To implement rules, you must associate them with a web ACL (p. 2209).

For more information, see CreateRule in the *AWS WAF API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAF::Rule",
  "Properties" : {
    "MetricName" : String,
    "Name" : String,
    "Predicates" : [ Predicate, ... ]
  }
}
```

YAML

```
Type: "AWS::WAF::Rule"
Properties:
  MetricName: String
  Name: String
  Predicates:
    - Predicate
```

Properties

`MetricName`

A friendly name or description for the metrics of the rule. For valid values, see the `MetricName` parameter for the `CreateRule` action in the *AWS WAF API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Name`

A friendly name or description of the rule.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Predicates`

The `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects to include in a rule. If you add more than one predicate to a rule, a request must match all conditions in order to be allowed or blocked.

Required: No

Type: List of AWS WAF Rule Predicates (p. 2199)

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

Associate an IPSet with a Web ACL Rule

The following example associates the `MyIPSetBlacklist IPSet` object with a web ACL rule.

JSON

```
"MyIPSetRule" : {
  "Type": "AWS::WAF::Rule",
  "Properties": {
    "Name": "MyIPSetRule",
    "MetricName" : "MyIPSetRule",
    "Predicates": [
      {
```

```
        "DataId" : {  "Ref" : "MyIPSetBlacklist" },
        "Negated" : false,
        "Type" : "IPMatch"
      }
    ]
  }
}
```

YAML

```
MyIPSetRule:
  Type: "AWS::WAF::Rule"
  Properties:
    Name: "MyIPSetRule"
    MetricName: "MyIPSetRule"
    Predicates:
      -
        DataId:
          Ref: "MyIPSetBlacklist"
        Negated: false
        Type: "IPMatch"
```

AWS WAF Rule Predicates

`Predicates` is a property of the AWS::WAF::Rule (p. 2197) resource that specifies the `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects to include in an AWS WAF rule. If you add more than one predicate to a rule, an incoming request must match all of the specifications in the predicates to be allowed or blocked.

Syntax

JSON

```
{
  "DataId" : String,
  "Negated" : Boolean,
  "Type" : String
}
```

YAML

```
DataId: String
Negated: Boolean
Type: String
```

Properties

`DataId`

The unique identifier of a predicate, such as the ID of a `ByteMatchSet` or `IPSet`.

Required: Yes

Type: String

`Negated`

Whether to use the settings or the negated settings that you specified in the `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects.

Specify `false` if you want AWS WAF to allow, block, or count requests based on the settings in the specified `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects. For example, if an `IPSet` object includes the IP address `192.0.2.44`, AWS WAF allows, blocks, or counts requests originating from that IP address.

Specify `true` if you want AWS WAF to allow, block, or count requests based on the negated settings in the `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects. For example, if an `IPSet` object includes the IP address `192.0.2.44`, AWS WAF allows, blocks, or counts requests originating from all IP addresses except 192.0.2.44.

Required: Yes

Type: Boolean

`Type`

The type of predicate in a rule, such as an `IPSet` (`IPMatch`). For valid values, see the `Type` contents of the Predicate data type in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS::WAF::SizeConstraintSet

The `AWS::WAF::SizeConstraintSet` resource specifies a size constraint that AWS WAF uses to check the size of a web request and which parts of the request to check. For more information, see CreateSizeConstraintSet in the *AWS WAF API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAF::SizeConstraintSet",
  "Properties" : {
    "Name" : String,
    "SizeConstraints" : [ SizeConstraint, ... ]
  }
}
```

YAML

```
Type: "AWS::WAF::SizeConstraintSet"
Properties:
  Name: String
  SizeConstraints:
    - SizeConstraint
```

Properties

`Name`

A friendly name or description for the `SizeConstraintSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SizeConstraints`

The size constraint and the part of the web request to check.

Required: Yes

Type: List of AWS WAF SizeConstraintSet SizeConstraint (p. 2204)

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following examples show you how to define a size constraint, add it to a rule, and add the rule to a web access control list (ACL).

Define a Size Constraint

The following example checks that the body of an HTTP request equals `4096` bytes.

JSON

```
"MySizeConstraint": {
  "Type": "AWS::WAF::SizeConstraintSet",
  "Properties": {
    "Name": "SizeConstraints",
    "SizeConstraints": [
      {
        "ComparisonOperator": "EQ",
        "FieldToMatch": {
          "Type": "BODY"
        },
        "Size": "4096",
        "TextTransformation": "NONE"
      }
    ]
  }
}
```

YAML

```
  MySizeConstraint:
    Type: "AWS::WAF::SizeConstraintSet"
    Properties:
      Name: "SizeConstraints"
```

```
      SizeConstraints:
        -
          ComparisonOperator: "EQ"
          FieldToMatch:
            Type: "BODY"
          Size: "4096"
          TextTransformation: "NONE"
```

Associate a `SizeConstraintSet` with a Web ACL Rule

The following example associates the `MySizeConstraint` object with a web ACL rule.

JSON

```
"SizeConstraintRule" : {
  "Type": "AWS::WAF::Rule",
  "Properties": {
    "Name": "SizeConstraintRule",
    "MetricName" : "SizeConstraintRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "MySizeConstraint" },
        "Negated" : false,
        "Type" : "SizeConstraint"
      }
    ]
  }
}
```

YAML

```
SizeConstraintRule:
  Type: "AWS::WAF::Rule"
  Properties:
    Name: "SizeConstraintRule"
    MetricName: "SizeConstraintRule"
    Predicates:
      -
        DataId:
          Ref: "MySizeConstraint"
        Negated: false
        Type: "SizeConstraint"
```

Create a Web ACL

The following example associates the `SizeConstraintRule` rule with a web ACL. The web ACL blocks all requests except for requests with a body size equal to `4096` bytes.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAF::WebACL",
  "Properties": {
    "Name": "Web ACL to allow requests with a specific size",
    "DefaultAction": {
      "Type": "BLOCK"
    },
    "MetricName" : "SizeConstraintWebACL",
    "Rules": [
      {
```

```
        "Action" : {
          "Type" : "ALLOW"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "SizeConstraintRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAF::WebACL"
  Properties:
    Name: "Web ACL to allow requests with a specific size"
    DefaultAction:
      Type: "BLOCK"
    MetricName: "SizeConstraintWebACL"
    Rules:
      -
        Action:
          Type: "ALLOW"
        Priority: 1
        RuleId:
          Ref: "SizeConstraintRule"
```

AWS WAF SizeConstraintSet SizeConstraint FieldToMatch

`FieldToMatch` is a property of the AWS WAF SizeConstraintSet SizeConstraint (p. 2204) property that specifies the part of a web request that you want AWS WAF to check for a size constraint, such as a specific header or a query string.

Syntax

JSON

```
{
  "Data" : String,
  "Type" : String
}
```

YAML

```
Data: String
Type: String
```

Properties

`Data`

If you specify `HEADER` for the `Type` property, the name of the header that AWS WAF searches for, such as `User-Agent` or `Referer`. If you specify any other value for the `Type` property, do not specify this property.

Required: Conditional

Type: String

`Type`

The part of the web request in which AWS WAF searches for the target string. For valid values, see FieldToMatch in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS WAF SizeConstraintSet SizeConstraint

`SizeConstraint` is a property of the AWS::WAF::SizeConstraintSet (p. 2200) resource that specifies a size constraint and which part of a web request that you want AWS WAF to constrain.

Syntax

JSON

```
{
  "ComparisonOperator" : String,
  "FieldToMatch" : Field to match,
  "Size" : String,
  "TextTransformation" : String
}
```

YAML

```
ComparisonOperator: String
FieldToMatch:
  Field to match
Size: String
TextTransformation: String
```

Properties

`ComparisonOperator`

The type of comparison that you want AWS WAF to perform. AWS WAF uses this value in combination with the `Size` and `FieldToMatch` property values to check if the size constraint is a match. For more information and valid values, see the `ComparisonOperator` content for the SizeConstraint data type in the *AWS WAF API Reference*.

Required: Yes

Type: String

`FieldToMatch`

The part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Required: Yes

Type: AWS WAF SizeConstraintSet SizeConstraint FieldToMatch (p. 2203)

`Size`

The size in bytes that you want AWS WAF to compare against the size of the specified `FieldToMatch`. AWS WAF uses `Size` in combination with the `ComparisonOperator` and

`FieldToMatch` property values to check if the size constraint of a web request is a match. For more information and valid values, see the `Size` content for the SizeConstraint data type in the *AWS WAF API Reference*.

Required: Yes

Type: Integer

`TextTransformation`

Specifies how AWS WAF processes the `FieldToMatch` property before inspecting a request for a match. Text transformations eliminate some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF. If you specify a transformation, AWS WAF transforms the `FieldToMatch` before inspecting a web request for a match.

For example, AWS WAF can replace white space characters (such as `\t` and `\n`) with a single space. For valid values, see the `TextTransformation` content for the SizeConstraint data type in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS::WAF::SqlInjectionMatchSet

The `AWS::WAF::SqlInjectionMatchSet` resource creates an AWS WAF `SqlInjectionMatchSet`, which you use to allow, block, or count requests that contain malicious SQL code in a specific part of web requests. For more information, see CreateSqlInjectionMatchSet in the *AWS WAF API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAF::SqlInjectionMatchSet",
  "Properties" : {
    "Name" : String,
    "SqlInjectionMatchTuples" : [ SqlInjectionMatchTuple, ... ]
  }
}
```

YAML

```
Type: "AWS::WAF::SqlInjectionMatchSet"
Properties:
  Name: String
  SqlInjectionMatchTuples:
    - SqlInjectionMatchTuple
```

Properties

`Name`

A friendly name or description of the `SqlInjectionMatchSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SqlInjectionMatchTuples`

The parts of web requests that you want AWS WAF to inspect for malicious SQL code and, if you want AWS WAF to inspect a header, the name of the header.

Required: No

Type: List of AWS WAF SqlInjectionMatchSet SqlInjectionMatchTuples (p. 2209)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Find SQL Injections

The following example looks for snippets of SQL code in the query string of an HTTP request.

JSON

```
"SqlInjDetection": {
  "Type": "AWS::WAF::SqlInjectionMatchSet",
  "Properties": {
    "Name": "Find SQL injections in the query string",
    "SqlInjectionMatchTuples": [
      {
        "FieldToMatch" : {
          "Type": "QUERY_STRING"
        },
        "TextTransformation" : "URL_DECODE"
      }
    ]
  }
}
```

YAML

```
SqlInjDetection:
  Type: "AWS::WAF::SqlInjectionMatchSet"
  Properties:
    Name: "Find SQL injections in the query string"
    SqlInjectionMatchTuples:
      -
        FieldToMatch:
          Type: "QUERY_STRING"
        TextTransformation: "URL_DECODE"
```

Associate a SQL Injection Match Set with a Web ACL Rule

The following example associates the `SqlInjDetection` match set with a web access control list (ACL) rule.

JSON

```
"SqlInjRule" : {
  "Type": "AWS::WAF::Rule",
  "Properties": {
    "Name": "SqlInjRule",
    "MetricName" : "SqlInjRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "SqlInjDetection" },
        "Negated" : false,
        "Type" : "SqlInjectionMatch"
      }
    ]
  }
}
```

YAML

```
SqlInjRule:
  Type: "AWS::WAF::Rule"
  Properties:
    Name: "SqlInjRule"
    MetricName: "SqlInjRule"
    Predicates:
      -
        DataId:
          Ref: "SqlInjDetection"
        Negated: false
        Type: "SqlInjectionMatch"
```

Create a Web ACL

The following example associates the `SqlInjRule` rule with a web ACL. The web ACL allows all requests except for ones with SQL code in the query string of a request.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAF::WebACL",
  "Properties": {
    "Name": "Web ACL to block SQL injection in the query string",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "SqlInjWebACL",
    "Rules": [
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "SqlInjRule" }
      }
    ]
  }
```

```
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAF::WebACL"
  Properties:
    Name: "Web ACL to block SQL injection in the query string"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "SqlInjWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "SqlInjRule"
```

AWS WAF SqlInjectionMatchSet SqlInjectionMatchTuples FieldToMatch

`FieldToMatch` is a property of the AWS WAF ByteMatchSet ByteMatchTuples (p. 2191) property that specifies the part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Syntax

JSON

```
{
  "Data" : String,
  "Type" : String
}
```

YAML

```
Data: String
Type: String
```

Properties

`Data`

If you specify `HEADER` for the `Type` property, the name of the header that AWS WAF searches for, such as `User-Agent` or `Referer`. If you specify any other value for the `Type` property, do not specify this property.

Required: Conditional

Type: String

`Type`

The part of the web request in which AWS WAF searches for the target string. For valid values, see FieldToMatch in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS WAF SqlInjectionMatchSet SqlInjectionMatchTuples

`SqlInjectionMatchTuples` is a property of the AWS::WAF::SqlInjectionMatchSet (p. 2205) resource that specifies the parts of web requests that AWS WAF inspects for SQL code.

Syntax

JSON

```
{
  "FieldToMatch" : Field to match,
  "TextTransformation" : String
}
```

YAML

```
FieldToMatch:
  Field to match
TextTransformation: String
```

Properties

`FieldToMatch`

The part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Required: Yes

Type: AWS WAF ByteMatchSet ByteMatchTuples FieldToMatch (p. 2193)

`TextTransformation`

Text transformations eliminate some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF. If you specify a transformation, AWS WAF transforms the target string value before inspecting a web request for a match. For valid values, see the `TextTransformation` content for the SqlInjectionMatchTuple data type in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS::WAF::WebACL

The `AWS::WAF::WebACL` resource creates an AWS WAF web access control group (ACL) containing the rules that identify the Amazon CloudFront (CloudFront) web requests that you want to allow, block, or count. For more information, see CreateWebACL in the *AWS WAF API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAF::WebACL",
```

```
  "Properties" : {
    "DefaultAction" : Action,
    "MetricName" : String,
    "Name" : String,
    "Rules" : [ Rule, ... ]
  }
}
```

YAML

```
Type: "AWS::WAF::WebACL"
Properties:
  DefaultAction:
    Action
  MetricName: String
  Name: String
  Rules:
    - Rule
```

Properties

`DefaultAction`

The action that you want AWS WAF to take when a request doesn't match the criteria in any of the rules that are associated with the web ACL.

Required: Yes

Type: AWS WAF WebACL Action (p. 2213)

Update requires: No interruption (p. 120)

`MetricName`

A friendly name or description for the Amazon CloudWatch metric of this web ACL. For valid values, see the `MetricName` parameter of the CreateWebACL action in the *AWS WAF API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Name`

A friendly name or description of the web ACL.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Rules`

The rules to associate with the web ACL and the settings for each rule.

Required: No

Type: List of AWS WAF WebACL ActivatedRule (p. 2214)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Create a Web ACL

The following example defines a web ACL that allows, by default, any web request. However, if the request matches any rule, AWS WAF blocks the request. AWS WAF evaluates each rule in priority order, starting with the lowest value.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAF::WebACL",
  "Properties": {
    "Name": "WebACL to with three rules",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "MyWebACL",
    "Rules": [
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "MyRule" }
      },
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 2,
        "RuleId" : { "Ref" : "BadReferersRule" }
      },
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 3,
        "RuleId" : { "Ref" : "SqlInjRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAF::WebACL"
  Properties:
```

```
    Name: "WebACL to with three rules"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "MyWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "MyRule"
      -
        Action:
          Type: "BLOCK"
        Priority: 2
        RuleId:
          Ref: "BadReferersRule"
      -
        Action:
          Type: "BLOCK"
        Priority: 3
        RuleId:
          Ref: "SqlInjRule"
```

Associate a Web ACL with a CloudFront Distribution

The follow example associates the `MyWebACL` web ACL with a CloudFront distribution. The web ACL restricts which requests can access content served by CloudFront.

JSON

```
"myDistribution": {
  "Type": "AWS::CloudFront::Distribution",
  "Properties": {
    "DistributionConfig": {
      "WebACLId": { "Ref" : "MyWebACL" },
      "Origins": [
        {
          "DomainName": "test.example.com",
          "Id": "myCustomOrigin",
          "CustomOriginConfig": {
            "HTTPPort": "80",
            "HTTPSPort": "443",
            "OriginProtocolPolicy": "http-only"
          }
        }
      ],
      "Enabled": "true",
      "Comment": "TestDistribution",
      "DefaultRootObject": "index.html",
      "DefaultCacheBehavior": {
        "TargetOriginId": "myCustomOrigin",
        "SmoothStreaming" : "false",
        "ForwardedValues": {
          "QueryString": "false",
          "Cookies" : { "Forward" : "all" }
        },
        "ViewerProtocolPolicy": "allow-all"
      },
      "CustomErrorResponses" : [
        {
          "ErrorCode" : "404",
          "ResponsePagePath" : "/error-pages/404.html",
          "ResponseCode" : "200",
```

```
          "ErrorCachingMinTTL" : "30"
        }
      ],
      "PriceClass" : "PriceClass_200",
      "Restrictions" : {
        "GeoRestriction" : {
          "RestrictionType" : "whitelist",
          "Locations" : [ "AQ", "CV" ]
        }
      },
      "ViewerCertificate" : { "CloudFrontDefaultCertificate" : "true" }
    }
  }
}
```

YAML

```
myDistribution:
  Type: "AWS::CloudFront::Distribution"
  Properties:
    DistributionConfig:
      WebACLId:
        Ref: "MyWebACL"
      Origins:
        -
          DomainName: "test.example.com"
          Id: "myCustomOrigin"
          CustomOriginConfig:
            HTTPPort: "80"
            HTTPSPort: "443"
            OriginProtocolPolicy: "http-only"
      Enabled: "true"
      Comment: "TestDistribution"
      DefaultRootObject: "index.html"
      DefaultCacheBehavior:
        TargetOriginId: "myCustomOrigin"
        SmoothStreaming: "false"
        ForwardedValues:
          QueryString: "false"
          Cookies:
            Forward: "all"
        ViewerProtocolPolicy: "allow-all"
      CustomErrorResponses:
        -
          ErrorCode: "404"
          ResponsePagePath: "/error-pages/404.html"
          ResponseCode: "200"
          ErrorCachingMinTTL: "30"
      PriceClass: "PriceClass_200"
      Restrictions:
        GeoRestriction:
          RestrictionType: "whitelist"
          Locations:
            - "AQ"
            - "CV"
      ViewerCertificate:
        CloudFrontDefaultCertificate: "true"
```

AWS WAF WebACL Action

`Action` is a property of the AWS::WAF::WebACL (p. 2209) resource and the AWS WAF WebACL ActivatedRule (p. 2214) property that specifies the action AWS WAF takes when a web request matches or doesn't match all rule conditions.

Syntax

JSON

```
{
  "Type" : String
}
```

YAML

```
Type: String
```

Properties

`Type`

For actions that are associated with a rule, the action that AWS WAF takes when a web request matches all conditions in a rule.

For the default action of a web access control list (ACL), the action that AWS WAF takes when a web request doesn't match all conditions in any rule.

For valid value, see the `Type` contents of the WafAction data type in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS WAF WebACL ActivatedRule

`ActivatedRule` is a property of the AWS::WAF::WebACL (p. 2209) resource that specifies a rule to associate with an AWS WAF web access control list (ACL), and the rule's settings.

Syntax

JSON

```
{
  "Action" : AWS WAF WebACL Action
  "Priority" : Integer,
  "RuleId" : String
}
```

YAML

```
Action: AWS WAF WebACL Action
Priority: Integer
RuleId: String
```

Properties

`Action`

The action that Amazon CloudFront (CloudFront) or AWS WAF takes when a web request matches all conditions in the rule, such as allow, block, or count the request.

Required: No

Type: AWS WAF WebACL Action (p. 2213)

`Priority`

The order in which AWS WAF evaluates the rules in a web ACL. AWS WAF evaluates rules with a lower value before rules with a higher value. The value must be a unique integer. If you have multiple rules in a web ACL, the priority numbers do not need to be consecutive.

Required: Yes

Type: Integer

`RuleId`

The ID of an AWS WAF rule (p. 2197) to associate with a web ACL.

Required: Yes

Type: String

AWS::WAF::XssMatchSet

The `AWS::WAF::XssMatchSet` resource specifies the parts of web requests that you want AWS WAF to inspect for cross-site scripting attacks and the name of the header to inspect. For more information, see XssMatchSet in the *AWS WAF API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAF::XssMatchSet",
  "Properties" : {
    "Name" : String,
    "XssMatchTuples" : [ XssMatchTuple, ... ]
  }
}
```

YAML

```
Type: "AWS::WAF::XssMatchSet"
Properties:
  Name: String
  XssMatchTuples:
    - XssMatchTuple
```

Properties

`Name`

A friendly name or description for the `XssMatchSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`XssMatchTuples`

The parts of web requests that you want to inspect for cross-site scripting attacks.

Required: No

Type: List of AWS WAF XssMatchSet XssMatchTuple (p. 2219)

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Define Which Part of a Request to Check for Cross-site Scripting

The following example looks for cross-site scripting in the URI or query string of an HTTP request.

JSON

```
"DetectXSS": {
  "Type": "AWS::WAF::XssMatchSet",
  "Properties": {
    "Name": "XssMatchSet",
    "XssMatchTuples": [
      {
        "FieldToMatch": {
          "Type": "URI"
        },
        "TextTransformation": "NONE"
      },
      {
        "FieldToMatch": {
          "Type": "QUERY_STRING"
        },
        "TextTransformation": "NONE"
      }
    ]
  }
}
```

YAML

```
DetectXSS:
  Type: "AWS::WAF::XssMatchSet"
  Properties:
    Name: "XssMatchSet"
    XssMatchTuples:
      -
        FieldToMatch:
          Type: "URI"
        TextTransformation: "NONE"
      -
        FieldToMatch:
```

```
          Type: "QUERY_STRING"
        TextTransformation: "NONE"
```

Associate an XssMatchSet with a Web ACL Rule

The following example associates the `DetectXSS` match set with a web access control list (ACL) rule.

JSON

```
"XSSRule" : {
  "Type": "AWS::WAF::Rule",
  "Properties": {
    "Name": "XSSRule",
    "MetricName" : "XSSRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "DetectXSS" },
        "Negated" : false,
        "Type" : "XssMatch"
      }
    ]
  }
}
```

YAML

```
XSSRule:
  Type: "AWS::WAF::Rule"
  Properties:
    Name: "XSSRule"
    MetricName: "XSSRule"
    Predicates:
      -
        DataId:
          Ref: "DetectXSS"
        Negated: false
        Type: "XssMatch"
```

Create a Web ACL

The following example associates the `XSSRule` rule with a web ACL. The web ACL allows all requests except for ones that contain cross-site scripting in the URI or query string of an HTTP request.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAF::WebACL",
  "Properties": {
    "Name": "Web ACL to block cross-site scripting",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "DetectXSSWebACL",
    "Rules": [
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "XSSRule" }
      }
    ]
```

```
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAF::WebACL"
  Properties:
    Name: "Web ACL to block cross-site scripting"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "DetectXSSWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "XSSRule"
```

AWS WAF XssMatchSet XssMatchTuple FieldToMatch

`FieldToMatch` is a property of the AWS WAF XssMatchSet XssMatchTuple (p. 2219) property that specifies the part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Syntax

JSON

```
{
  "Data" : String,
  "Type" : String
}
```

YAML

```
Data: String
Type: String
```

Properties

`Data`

If you specify `HEADER` for the `Type` property, the name of the header that AWS WAF searches for, such as `User-Agent` or `Referer`. If you specify any other value for the `Type` property, do not specify this property.

Required: Conditional

Type: String

`Type`

The part of the web request in which AWS WAF searches for the target string. For valid values, see FieldToMatch in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS WAF XssMatchSet XssMatchTuple

`XssMatchTuple` is a property of the AWS::WAF::XssMatchSet (p. 2215) resource that specifies the part of a web request that you want AWS WAF to inspect for cross-site scripting attacks.

Syntax

JSON

```
{
  "FieldToMatch" : Field to match,
  "TextTransformation" : String
}
```

YAML

```
FieldToMatch:
  Field to match
TextTransformation: String
```

Properties

`FieldToMatch`

The part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Required: Yes

Type: AWS WAF XssMatchSet XssMatchTuple FieldToMatch (p. 2218)

`TextTransformation`

Specifies how AWS WAF processes the `FieldToMatch` property before inspecting a request for a match. Text transformations eliminate some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF. If you specify a transformation, AWS WAF transforms the `FieldToMatch` parameter before inspecting a web request for a match.

For example, AWS WAF can replace white space characters (such as `\t` and `\n`) with a single space. For valid values, see the `TextTransformation` content for the XssMatchTuple data type in the *AWS WAF API Reference*.

Required: Yes

Type: String

AWS WAF Regional Resource Types Reference

This section contains reference information for all AWS WAF Regional resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::WAFRegional::data-type-name
```

Topics

- AWS::WAFRegional::ByteMatchSet (p. 2220)

- AWS::WAFRegional::IPSet (p. 2225)
- AWS::WAFRegional::Rule (p. 2229)
- AWS::WAFRegional::SizeConstraintSet (p. 2232)
- AWS::WAFRegional::SqlInjectionMatchSet (p. 2237)
- AWS::WAFRegional::WebACL (p. 2241)
- AWS::WAFRegional::WebACLAssociation (p. 2247)
- AWS::WAFRegional::XssMatchSet (p. 2248)

AWS::WAFRegional::ByteMatchSet

The `AWS::WAFRegional::ByteMatchSet` resource creates an AWS WAF Regional `ByteMatchSet` that identifies a part of a web request that you want to inspect. For more information, see CreateByteMatchSet in the *AWS WAF Regional API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAFRegional::ByteMatchSet",
  "Properties" : {
    "ByteMatchTuples" : [ Byte match tuple, ... ],
    "Name" : String
  }
}
```

YAML

```
Type: "AWS::WAFRegional::ByteMatchSet"
Properties:
  ByteMatchTuples:
    - Byte match tuple
  Name: String
```

Properties

`ByteMatchTuples`

Settings for the `ByteMatchSet`, such as the bytes (typically a string that corresponds with ASCII characters) that you want AWS WAF to search for in web requests.

Required: No

Type: List of AWS WAF Regional ByteMatchSet ByteMatchTuples (p. 2223)

Update requires: No interruption (p. 120)

`Name`

A friendly name or description of the `ByteMatchSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

HTTP Referers

The following example defines a set of HTTP referers to match.

JSON

```
"BadReferers": {
  "Type": "AWS::WAFRegional::ByteMatchSet",
  "Properties": {
    "Name": "ByteMatch for matching bad HTTP referers",
    "ByteMatchTuples": [
      {
        "FieldToMatch" : {
          "Type": "HEADER",
          "Data": "referer"
        },
        "TargetString" : "badrefer1",
        "TextTransformation" : "NONE",
        "PositionalConstraint" : "CONTAINS"
      },
      {
        "FieldToMatch" : {
          "Type": "HEADER",
          "Data": "referer"
        },
        "TargetString" : "badrefer2",
        "TextTransformation" : "NONE",
        "PositionalConstraint" : "CONTAINS"
      }
    ]
  }
}
```

YAML

```
BadReferers:
  Type: "AWS::WAFRegional::ByteMatchSet"
  Properties:
    Name: "ByteMatch for matching bad HTTP referers"
    ByteMatchTuples:
      -
        FieldToMatch:
          Type: "HEADER"
          Data: "referer"
        TargetString: "badrefer1"
        TextTransformation: "NONE"
        PositionalConstraint: "CONTAINS"
      -
```

```
        FieldToMatch:
          Type: "HEADER"
          Data: "referer"
        TargetString: "badrefer2"
        TextTransformation: "NONE"
        PositionalConstraint: "CONTAINS"
```

Associate a ByteMatchSet with a Web ACL Rule

The following example associates the `BadReferers` byte match set with a web access control list (ACL) rule.

JSON

```
"BadReferersRule" : {
  "Type": "AWS::WAFRegional::Rule",
  "Properties": {
    "Name": "BadReferersRule",
    "MetricName" : "BadReferersRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "BadReferers" },
        "Negated" : false,
        "Type" : "ByteMatch"
      }
    ]
  }
}
```

YAML

```
BadReferersRule:
  Type: "AWS::WAFRegional::Rule"
  Properties:
    Name: "BadReferersRule"
    MetricName: "BadReferersRule"
    Predicates:
      -
        DataId:
          Ref: "BadReferers"
        Negated: false
        Type: "ByteMatch"
```

Create a Web ACL

The following example associates the `BadReferersRule` rule with a web ACL. The web ACL allows all requests except for ones with referers that match the `BadReferersRule` rule.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAFRegional::WebACL",
  "Properties": {
    "Name": "WebACL to block blacklisted IP addresses",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "MyWebACL",
    "Rules": [
      {
        "Action" : {
```

```
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "BadReferersRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAFRegional::WebACL"
  Properties:
    Name: "WebACL to block blacklisted IP addresses"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "MyWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "BadReferersRule"
```

AWS WAF Regional ByteMatchSet ByteMatchTuples

`ByteMatchTuples` is a property of the AWS::WAFRegional::ByteMatchSet (p. 2220) resource that specifies settings for an AWS WAF Regional `ByteMatchSet` resource, such as the bytes (typically a string that corresponds with ASCII characters) that you want AWS WAF to search for in web requests.

Syntax

JSON

```
{
  "FieldToMatch" : Field to match,
  "PositionalConstraint" : String,
  "TargetString" : String,
  "TargetStringBase64" : String,
  "TextTransformation" : String
}
```

YAML

```
FieldToMatch:
  Field to match
PositionalConstraint: String
TargetString: String
TargetStringBase64: String
TextTransformation: String
```

Properties

`FieldToMatch`

The part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Required: Yes

Type: AWS WAF Regional ByteMatchSet ByteMatchTuples FieldToMatch (p. 2225)

`PositionalConstraint`

How AWS WAF finds matches within the part of the web request in which you are searching. For valid values, see the `PositionalConstraint` content for the ByteMatchTuple data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

`TargetString`

The value that AWS WAF searches for. AWS CloudFormation encodes in base64 this value before sending it to AWS WAF.

AWS WAF searches for this value in a specific part of web requests, which you define in the `FieldToMatch` property.

Valid values depend on the `Type` value in the `FieldToMatch` property. For example, for a `METHOD` type, you must specify HTTP methods, such as `DELETE, GET, HEAD, OPTIONS, PATCH, POST,` and `PUT`. For more information, see the `TargetString` content for the ByteMatchTuple data type in the *AWS WAF Regional API Reference*.

Required: Conditional. You must specify this property or the `TargetStringBase64` property.

Type: String

`TargetStringBase64`

The base64-encoded value that AWS WAF searches for. AWS CloudFormation sends this value to AWS WAF without encoding it.

AWS WAF searches for this value in a specific part of web requests, which you define in the `FieldToMatch` property.

Valid values depend on the `Type` value in the `FieldToMatch` property. For example, for a `METHOD` type, you must specify HTTP methods, such as `DELETE, GET, HEAD, OPTIONS, PATCH, POST,` and `PUT`. For more information, see the `TargetString` content for the ByteMatchTuple data type in the *AWS WAF Regional API Reference*.

Required: Conditional. You must specify this property or the `TargetString` property.

Type: String

`TextTransformation`

Specifies how AWS WAF processes the target string value. Text transformations eliminate some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF. If you specify a transformation, AWS WAF transforms the target string value before inspecting a web request for a match.

For example, AWS WAF can replace whitespace characters (such as `\t` and `\n`) with a single space. For valid values, see the `TextTransformation` content for the ByteMatchTuple data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

AWS WAF Regional ByteMatchSet ByteMatchTuples FieldToMatch

`FieldToMatch` is a property of the AWS WAF Regional ByteMatchSet ByteMatchTuples (p. 2223) property that specifies the part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Syntax

JSON

```
{
  "Data" : String,
  "Type" : String
}
```

YAML

```
Data: String
Type: String
```

Properties

`Data`

If you specify `HEADER` for the `Type` property, the name of the header that AWS WAF searches for, such as `User-Agent` or `Referer`. If you specify any other value for the `Type` property, do not specify this property.

Required: Conditional

Type: String

`Type`

The part of the web request in which AWS WAF searches for the target string. For valid values, see FieldToMatch in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

AWS::WAFRegional::IPSet

The `AWS::WAFRegional::IPSet` resource creates an AWS WAF Regional `IPSet` that specifies which web requests to permit or block based on the IP addresses from which the requests originate. For more information, see CreateIPSet in the *AWS WAF Regional API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAFRegional::IPSet",
  "Properties" : {
    "IPSetDescriptors" : [ IPSet descriptor, ... ],
    "Name" : String
  }
```

```
}
```

YAML

```
Type: "AWS::WAFRegional::IPSet"
Properties:
  IPSetDescriptors:
    - IPSet descriptor
  Name: String
```

Properties

`IPSetDescriptors`

The IP address type and IP address range (in CIDR notation) from which web requests originate. If you associate the `IPSet` with a web ACL (p. 2241) that is associated with a Amazon CloudFront (CloudFront) distribution, this descriptor is the value of one of the following fields in the CloudFront access logs:

`c-ip`

If the viewer did not use an HTTP proxy or a load balancer to send the request

`x-forwarded-for`

If the viewer did use an HTTP proxy or a load balancer to send the request

Required: No

Type: List of AWS WAF Regional IPSet IPSetDescriptors (p. 2228)

Update requires: No interruption (p. 120)

`Name`

A friendly name or description of the `IPSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Define IP Addresses

The following example defines a set of IP addresses for a web access control list (ACL) rule.

JSON

```
"MyIPSetBlacklist": {
```

```
  "Type": "AWS::WAFRegional::IPSet",
  "Properties": {
    "Name": "IPSet for blacklisted IP addresses",
    "IPSetDescriptors": [
      {
        "Type" : "IPV4",
        "Value" : "192.0.2.44/32"
      },
      {
        "Type" : "IPV4",
        "Value" : "192.0.7.0/24"
      }
    ]
  }
}
```

YAML

```
MyIPSetBlacklist:
  Type: "AWS::WAFRegional::IPSet"
  Properties:
    Name: "IPSet for blacklisted IP addresses"
    IPSetDescriptors:
      -
        Type: "IPV4"
        Value: "192.0.2.44/32"
      -
        Type: "IPV4"
        Value: "192.0.7.0/24"
```

Associate an IPSet with a Web ACL Rule

The following example associates the `MyIPSetBlacklist` IP Set with a web ACL rule.

JSON

```
"MyIPSetRule" : {
  "Type": "AWS::WAFRegional::Rule",
  "Properties": {
    "Name": "MyIPSetRule",
    "MetricName" : "MyIPSetRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "MyIPSetBlacklist" },
        "Negated" : false,
        "Type" : "IPMatch"
      }
    ]
  }
}
```

YAML

```
MyIPSetRule:
  Type: "AWS::WAFRegional::Rule"
  Properties:
    Name: "MyIPSetRule"
    MetricName: "MyIPSetRule"
    Predicates:
      -
        DataId:
```

```
          Ref: "MyIPSetBlacklist"
        Negated: false
        Type: "IPMatch"
```

Create a Web ACL

The following example associates the `MyIPSetRule` rule with a web ACL. The web ACL allows requests that originate from all IP addresses except for addresses that are defined in the `MyIPSetRule`.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAFRegional::WebACL",
  "Properties": {
    "Name": "WebACL to block blacklisted IP addresses",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "MyWebACL",
    "Rules": [
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "MyIPSetRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAFRegional::WebACL"
  Properties:
    Name: "WebACL to block blacklisted IP addresses"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "MyWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "MyIPSetRule"
```

AWS WAF Regional IPSet IPSetDescriptors

`IPSetDescriptors` is a property of the AWS::WAFRegional::IPSet (p. 2225) resource that specifies the IP address type and IP address range (in CIDR notation) from which web requests originate.

Syntax

JSON

```
{
  "Type" : String,
  "Value" : String
```

```
}
```

YAML

```
Type: String
Value: String
```

Properties

`Type`

The IP address type, such as `IPV4`. For valid values, see the `Type` contents of the IPSetDescriptor data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

`Value`

An IP address (in CIDR notation) that AWS WAF permits, blocks, or counts. For example, to specify a single IP address such as `192.0.2.44`, specify `192.0.2.44/32`. To specify a range of IP addresses such as `192.0.2.0` to `192.0.2.255`, specify `192.0.2.0/24`.

Required: Yes

Type: String

AWS::WAFRegional::Rule

The `AWS::WAFRegional::Rule` resource creates an AWS WAF Regional rule that specifies a combination of `IPSet`, `ByteMatchSet`, and `SqlInjectionMatchSet` objects that identify the web requests to allow, block, or count. To implement rules, you must associate them with a web ACL (p. 2241).

For more information, see CreateRule in the *AWS WAF Regional API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAFRegional::Rule",
  "Properties" : {
    "MetricName" : String,
    "Name" : String,
    "Predicates" : [ Predicate, ... ]
  }
}
```

YAML

```
Type: "AWS::WAFRegional::Rule"
Properties:
  MetricName: String
  Name: String
```

```
  Predicates:
    - Predicate
```

Properties

`MetricName`

A friendly name or description for the metrics of the rule. For valid values, see the `MetricName` parameter for the `CreateRule` action in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Name`

A friendly name or description of the rule.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Predicates`

The `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects to include in a rule. If you add more than one predicate to a rule, a request must match all conditions in order to be allowed or blocked.

Required: No

Type: List of AWS WAF Regional Rule Predicates (p. 2231)

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

Associate an IPSet with a Web ACL Rule

The following example associates the `MyIPSetBlacklist IPSet` object with a web ACL rule.

JSON

```
"MyIPSetRule" : {
  "Type": "AWS::WAFRegional::Rule",
  "Properties": {
    "Name": "MyIPSetRule",
    "MetricName" : "MyIPSetRule",
    "Predicates": [
```

```
      {
        "DataId" : {  "Ref" : "MyIPSetBlacklist" },
        "Negated" : false,
        "Type" : "IPMatch"
      }
    ]
  }
}
```

YAML

```
MyIPSetRule:
  Type: "AWS::WAFRegional::Rule"
  Properties:
    Name: "MyIPSetRule"
    MetricName: "MyIPSetRule"
    Predicates:
      -
        DataId:
          Ref: "MyIPSetBlacklist"
        Negated: false
        Type: "IPMatch"
```

AWS WAF Regional Rule Predicates

`Predicates` is a property of the AWS::WAFRegional::Rule (p. 2229) resource that specifies the `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects to include in an AWS WAF Regional rule. If you add more than one predicate to a rule, an incoming request must match all of the specifications in the predicates to be allowed or blocked.

Syntax

JSON

```
{
  "DataId" : String,
  "Negated" : Boolean,
  "Type" : String
}
```

YAML

```
DataId: String
Negated: Boolean
Type: String
```

Properties

`DataId`

The unique identifier of a predicate, such as the ID of a `ByteMatchSet` or `IPSet`.

Required: Yes

Type: String

`Negated`

Whether to use the settings or the negated settings that you specified in the `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects.

If you want AWS WAF to allow, block, or count requests based on the settings in the specified `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects, specify `false`. For example, if an `IPSet` object includes the IP address `192.0.2.44`, AWS WAF allows, blocks, or counts requests originating from that IP address.

If you want AWS WAF to allow, block, or count requests based on the *negated* settings in the `ByteMatchSet`, `IPSet`, `SizeConstraintSet`, `SqlInjectionMatchSet`, or `XssMatchSet` objects, specify `true`. For example, if an `IPSet` object includes the IP address `192.0.2.44`, AWS WAF allows, blocks, or counts requests originating from all IP addresses except 192.0.2.44.

Required: Yes

Type: Boolean

`Type`

The type of predicate in a rule, such as an `IPSet` (`IPMatch`). For valid values, see the `Type` contents of the Predicate data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

AWS::WAFRegional::SizeConstraintSet

The `AWS::WAFRegional::SizeConstraintSet` resource specifies a size constraint that AWS WAF uses to check the size of a web request and which parts of the request to check. For more information, see CreateSizeConstraintSet in the *AWS WAF Regional API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAFRegional::SizeConstraintSet",
  "Properties" : {
    "Name" : String,
    "SizeConstraints" : [ SizeConstraint, ... ]
  }
}
```

YAML

```
Type: "AWS::WAFRegional::SizeConstraintSet"
Properties:
  Name: String
  SizeConstraints:
    - SizeConstraint
```

Properties

`Name`

A friendly name or description for the `SizeConstraintSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SizeConstraints`

The size constraint and the part of the web request to check.

Required: Yes

Type: List of AWS WAF Regional SizeConstraintSet SizeConstraint (p. 2236)

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

The following examples show you how to define a size constraint, add it to a rule, and add the rule to a web access control list (ACL).

Define a Size Constraint

The following example checks that the body of an HTTP request equals `4096` bytes.

JSON

```
"MySizeConstraint": {
  "Type": "AWS::WAFRegional::SizeConstraintSet",
  "Properties": {
    "Name": "SizeConstraints",
    "SizeConstraints": [
      {
        "ComparisonOperator": "EQ",
        "FieldToMatch": {
          "Type": "BODY"
        },
        "Size": "4096",
        "TextTransformation": "NONE"
      }
    ]
  }
}
```

YAML

```
  MySizeConstraint:
    Type: "AWS::WAFRegional::SizeConstraintSet"
    Properties:
      Name: "SizeConstraints"
      SizeConstraints:
        -
          ComparisonOperator: "EQ"
```

```
          FieldToMatch:
            Type: "BODY"
          Size: "4096"
          TextTransformation: "NONE"
```

Associate a `SizeConstraintSet` with a Web ACL Rule

The following example associates the `MySizeConstraint` object with a web ACL rule.

JSON

```
"SizeConstraintRule" : {
  "Type": "AWS::WAFRegional::Rule",
  "Properties": {
    "Name": "SizeConstraintRule",
    "MetricName" : "SizeConstraintRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "MySizeConstraint" },
        "Negated" : false,
        "Type" : "SizeConstraint"
      }
    ]
  }
}
```

YAML

```
SizeConstraintRule:
  Type: "AWS::WAFRegional::Rule"
  Properties:
    Name: "SizeConstraintRule"
    MetricName: "SizeConstraintRule"
    Predicates:
      -
        DataId:
          Ref: "MySizeConstraint"
        Negated: false
        Type: "SizeConstraint"
```

Create a Web ACL

The following example associates the `SizeConstraintRule` rule with a web ACL. The web ACL blocks all requests except for requests with a body size equal to `4096` bytes.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAFRegional::WebACL",
  "Properties": {
    "Name": "Web ACL to allow requests with a specific size",
    "DefaultAction": {
      "Type": "BLOCK"
    },
    "MetricName" : "SizeConstraintWebACL",
    "Rules": [
      {
        "Action" : {
          "Type" : "ALLOW"
        },
        "Priority" : 1,
```

```
        "RuleId" : { "Ref" : "SizeConstraintRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAFRegional::WebACL"
  Properties:
    Name: "Web ACL to allow requests with a specific size"
    DefaultAction:
      Type: "BLOCK"
    MetricName: "SizeConstraintWebACL"
    Rules:
      -
        Action:
          Type: "ALLOW"
        Priority: 1
        RuleId:
          Ref: "SizeConstraintRule"
```

AWS WAF Regional SizeConstraintSet SizeConstraint FieldToMatch

`FieldToMatch` is a property of the AWS WAF Regional SizeConstraintSet SizeConstraint (p. 2236) property that specifies the part of a web request that you want AWS WAF to check for a size constraint, such as a specific header or a query string.

Syntax

JSON

```
{
  "Data" : String,
  "Type" : String
}
```

YAML

```
Data: String
Type: String
```

Properties

`Data`

If you specify `HEADER` for the `Type` property, the name of the header that AWS WAF searches for, such as `User-Agent` or `Referer`. If you specify any other value for the `Type` property, do not specify this property.

Required: Conditional

Type: String

`Type`

The part of the web request in which AWS WAF searches for the target string. For valid values, see FieldToMatch in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

AWS WAF Regional SizeConstraintSet SizeConstraint

`SizeConstraint` is a property of the AWS::WAFRegional::SizeConstraintSet (p. 2232) resource that specifies a size constraint and which part of a web request that you want AWS WAF to constrain.

Syntax

JSON

```
{
  "ComparisonOperator" : String,
  "FieldToMatch" : Field to match,
  "Size" : String,
  "TextTransformation" : String
}
```

YAML

```
ComparisonOperator: String
FieldToMatch:
  Field to match
Size: String
TextTransformation: String
```

Properties

`ComparisonOperator`

The type of comparison that you want AWS WAF to perform. AWS WAF uses this value in combination with the `Size` and `FieldToMatch` property values to check if the size constraint is a match. For more information and valid values, see the `ComparisonOperator` content for the SizeConstraint data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

`FieldToMatch`

The part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Required: Yes

Type: AWS WAF Regional SizeConstraintSet SizeConstraint FieldToMatch (p. 2235)

`Size`

The size in bytes that you want AWS WAF to compare against the size of the specified `FieldToMatch`. AWS WAF uses `Size` in combination with the `ComparisonOperator` and `FieldToMatch` property values to check if the size constraint of a web request is a match. For more information and valid values, see the `Size` content for the SizeConstraint data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: Integer

`TextTransformation`

Specifies how AWS WAF processes the `FieldToMatch` property before inspecting a request for a match. Text transformations eliminate some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF. If you specify a transformation, AWS WAF transforms the `FieldToMatch` before inspecting a web request for a match.

For example, AWS WAF can replace white space characters (such as `\t` and `\n`) with a single space. For valid values, see the `TextTransformation` content for the SizeConstraint data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

AWS::WAFRegional::SqlInjectionMatchSet

The `AWS::WAFRegional::SqlInjectionMatchSet` resource creates an AWS WAF Regional `SqlInjectionMatchSet`, which you use to allow, block, or count requests that contain malicious SQL code in a specific part of web requests. For more information, see CreateSqlInjectionMatchSet in the *AWS WAF Regional API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAFRegional::SqlInjectionMatchSet",
  "Properties" : {
    "Name" : String,
    "SqlInjectionMatchTuples" : [ SqlInjectionMatchTuple, ... ]
  }
}
```

YAML

```
Type: "AWS::WAFRegional::SqlInjectionMatchSet"
Properties:
  Name: String
  SqlInjectionMatchTuples:
    - SqlInjectionMatchTuple
```

Properties

`Name`

A friendly name or description of the `SqlInjectionMatchSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`SqlInjectionMatchTuples`

The parts of web requests that you want AWS WAF to inspect for malicious SQL code and, if you want AWS WAF to inspect a header, the name of the header.

Required: No

Type: List of AWS WAF Regional SqlInjectionMatchSet SqlInjectionMatchTuples (p. 2240)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Find SQL Injections

The following example looks for snippets of SQL code in the query string of an HTTP request.

JSON

```
"SqlInjDetection": {
  "Type": "AWS::WAFRegional::SqlInjectionMatchSet",
  "Properties": {
    "Name": "Find SQL injections in the query string",
    "SqlInjectionMatchTuples": [
      {
        "FieldToMatch" : {
          "Type": "QUERY_STRING"
        },
        "TextTransformation" : "URL_DECODE"
      }
    ]
  }
}
```

YAML

```
SqlInjDetection:
  Type: "AWS::WAFRegional::SqlInjectionMatchSet"
  Properties:
    Name: "Find SQL injections in the query string"
    SqlInjectionMatchTuples:
      -
        FieldToMatch:
          Type: "QUERY_STRING"
        TextTransformation: "URL_DECODE"
```

Associate a SQL Injection Match Set with a Web ACL Rule

The following example associates the `SqlInjDetection` match set with a web access control list (ACL) rule.

JSON

```
"SqlInjRule" : {
  "Type": "AWS::WAFRegional::Rule",
  "Properties": {
    "Name": "SqlInjRule",
    "MetricName" : "SqlInjRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "SqlInjDetection" },
        "Negated" : false,
        "Type" : "SqlInjectionMatch"
      }
    ]
  }
}
```

YAML

```
SqlInjRule:
  Type: "AWS::WAFRegional::Rule"
  Properties:
    Name: "SqlInjRule"
    MetricName: "SqlInjRule"
    Predicates:
      -
        DataId:
          Ref: "SqlInjDetection"
        Negated: false
        Type: "SqlInjectionMatch"
```

Create a Web ACL

The following example associates the `SqlInjRule` rule with a web ACL. The web ACL allows all requests except for ones with SQL code in the query string of a request.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAFRegional::WebACL",
  "Properties": {
    "Name": "Web ACL to block SQL injection in the query string",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "SqlInjWebACL",
    "Rules": [
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "SqlInjRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
```

```
  Type: "AWS::WAFRegional::WebACL"
  Properties:
    Name: "Web ACL to block SQL injection in the query string"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "SqlInjWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "SqlInjRule"
```

AWS WAF Regional SqlInjectionMatchSet SqlInjectionMatchTuples FieldToMatch

`FieldToMatch` is a property of the AWS WAF Regional ByteMatchSet ByteMatchTuples (p. 2223) property that specifies the part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Syntax

JSON

```
{
  "Data" : String,
  "Type" : String
}
```

YAML

```
Data: String
Type: String
```

Properties

`Data`

If you specify `HEADER` for the `Type` property, the name of the header that AWS WAF searches for, such as `User-Agent` or `Referer`. If you specify any other value for the `Type` property, do not specify this property.

Required: Conditional

Type: String

`Type`

The part of the web request in which AWS WAF searches for the target string. For valid values, see FieldToMatch in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

AWS WAF Regional SqlInjectionMatchSet SqlInjectionMatchTuples

`SqlInjectionMatchTuples` is a property of the AWS::WAFRegional::SqlInjectionMatchSet (p. 2237) resource that specifies the parts of web requests that AWS WAF inspects for SQL code.

Syntax

JSON

```
{
  "FieldToMatch" : Field to match,
  "TextTransformation" : String
}
```

YAML

```
FieldToMatch:
  Field to match
TextTransformation: String
```

Properties

`FieldToMatch`

The part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Required: Yes

Type: AWS WAF Regional ByteMatchSet ByteMatchTuples FieldToMatch (p. 2225)

`TextTransformation`

Specifies how AWS WAF processes the `FieldToMatch` property before inspecting a request for a match.

> **Note**
> Text transformations eliminate some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF. If you specify a transformation, AWS WAF transforms the target string value before inspecting a web request for a match. For valid values, see the `TextTransformation` content for the SqlInjectionMatchTuple data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

AWS::WAFRegional::WebACL

The `AWS::WAFRegional::WebACL` resource creates an AWS WAF Regional web access control group (ACL) containing the rules that identify the Amazon CloudFront (CloudFront) web requests that you want to allow, block, or count. For more information, see CreateWebACL in the *AWS WAF Regional API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAFRegional::WebACL",
```

```
  "Properties" : {
    "DefaultAction" : Action,
    "MetricName" : String,
    "Name" : String,
    "Rules" : [ Rule, ... ]
  }
}
```

YAML

```
Type: "AWS::WAFRegional::WebACL"
Properties:
  DefaultAction:
    Action
  MetricName: String
  Name: String
  Rules:
    - Rule
```

Properties

`DefaultAction`

The action that you want AWS WAF to take when a request doesn't match the criteria in any of the rules that are associated with the web ACL.

Required: Yes

Type: AWS WAF Regional WebACL Action (p. 2245)

Update requires: No interruption (p. 120)

`MetricName`

A friendly name or description for the Amazon CloudWatch metric of this web ACL. For valid values, see the `MetricName` parameter of the CreateWebACL action in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Name`

A friendly name or description of the web ACL.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`Rules`

The rules to associate with the web ACL and the settings for each rule.

Required: No

Type: List of AWS WAF Regional WebACL Rules (p. 2246)

Update requires: No interruption (p. 120)

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Create a Web ACL

The following example defines a web ACL that allows, by default, any web request. However, if the request matches any rule, AWS WAF blocks the request. AWS WAF evaluates each rule in priority order, starting with the lowest value.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAFRegional::WebACL",
  "Properties": {
    "Name": "WebACL to with three rules",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "MyWebACL",
    "Rules": [
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "MyRule" }
      },
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 2,
        "RuleId" : { "Ref" : "BadReferersRule" }
      },
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 3,
        "RuleId" : { "Ref" : "SqlInjRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAFRegional::WebACL"
  Properties:
```

```
    Name: "WebACL to with three rules"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "MyWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "MyRule"
      -
        Action:
          Type: "BLOCK"
        Priority: 2
        RuleId:
          Ref: "BadReferersRule"
      -
        Action:
          Type: "BLOCK"
        Priority: 3
        RuleId:
          Ref: "SqlInjRule"
```

Associate a Web ACL with a CloudFront Distribution

The follow example associates the `MyWebACL` web ACL with a CloudFront distribution. The web ACL restricts which requests can access content served by CloudFront.

JSON

```
"myDistribution": {
  "Type": "AWS::CloudFront::Distribution",
  "Properties": {
    "DistributionConfig": {
      "WebACLId": { "Ref" : "MyWebACL" },
      "Origins": [
        {
          "DomainName": "test.example.com",
          "Id": "myCustomOrigin",
          "CustomOriginConfig": {
            "HTTPPort": "80",
            "HTTPSPort": "443",
            "OriginProtocolPolicy": "http-only"
          }
        }
      ],
      "Enabled": "true",
      "Comment": "TestDistribution",
      "DefaultRootObject": "index.html",
      "DefaultCacheBehavior": {
        "TargetOriginId": "myCustomOrigin",
        "SmoothStreaming" : "false",
        "ForwardedValues": {
          "QueryString": "false",
          "Cookies" : { "Forward" : "all" }
        },
        "ViewerProtocolPolicy": "allow-all"
      },
      "CustomErrorResponses" : [
        {
          "ErrorCode" : "404",
          "ResponsePagePath" : "/error-pages/404.html",
          "ResponseCode" : "200",
```

```
          "ErrorCachingMinTTL" : "30"
        }
      ],
      "PriceClass" : "PriceClass_200",
      "Restrictions" : {
        "GeoRestriction" : {
          "RestrictionType" : "whitelist",
          "Locations" : [ "AQ", "CV" ]
        }
      },
      "ViewerCertificate" : { "CloudFrontDefaultCertificate" : "true" }
    }
  }
}
```

YAML

```
myDistribution:
  Type: "AWS::CloudFront::Distribution"
  Properties:
    DistributionConfig:
      WebACLId:
        Ref: "MyWebACL"
      Origins:
        -
          DomainName: "test.example.com"
          Id: "myCustomOrigin"
          CustomOriginConfig:
            HTTPPort: "80"
            HTTPSPort: "443"
            OriginProtocolPolicy: "http-only"
      Enabled: "true"
      Comment: "TestDistribution"
      DefaultRootObject: "index.html"
      DefaultCacheBehavior:
        TargetOriginId: "myCustomOrigin"
        SmoothStreaming: "false"
        ForwardedValues:
          QueryString: "false"
          Cookies:
            Forward: "all"
        ViewerProtocolPolicy: "allow-all"
      CustomErrorResponses:
        -
          ErrorCode: "404"
          ResponsePagePath: "/error-pages/404.html"
          ResponseCode: "200"
          ErrorCachingMinTTL: "30"
      PriceClass: "PriceClass_200"
      Restrictions:
        GeoRestriction:
          RestrictionType: "whitelist"
          Locations:
            - "AQ"
            - "CV"
      ViewerCertificate:
        CloudFrontDefaultCertificate: "true"
```

AWS WAF Regional WebACL Action

`Action` is a property of the AWS::WAFRegional::WebACL (p. 2241) resource and the AWS WAF Regional WebACL Rules (p. 2246) property that specifies the action AWS WAF takes when a web request matches or doesn't match all rule conditions.

Syntax

JSON

```
{
  "Type" : String
}
```

YAML

```
Type: String
```

Properties

`Type`

For actions that are associated with a rule, the action that AWS WAF takes when a web request matches all conditions in a rule.

For the default action of a web access control list (ACL), the action that AWS WAF takes when a web request doesn't match all conditions in any rule.

For valid value, see the `Type` contents of the WafAction data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

AWS WAF Regional WebACL Rules

`Rules` is a property of the AWS::WAFRegional::WebACL (p. 2241) resource that specifies the rule to associate with an AWS WAF Regional web access control list (ACL) and the rule's settings.

Syntax

JSON

```
{
  "Action" : String,
  "Priority" : Integer,
  "RuleId" : String
}
```

YAML

```
Action: String
Priority: Integer
RuleId: String
```

Properties

`Action`

The action that Amazon CloudFront (CloudFront) or AWS WAF takes when a web request matches all conditions in the rule, such as allow, block, or count the request.

Required: Yes

Type: AWS WAF Regional WebACL Action (p. 2245)

`Priority`

The order in which AWS WAF evaluates the rules in a web ACL. AWS WAF evaluates rules with a lower value before rules with a higher value. The value must be a unique integer. If you have multiple rules in a web ACL, the priority numbers do not need to be consecutive.

Required: Yes

Type: Integer

`RuleId`

The ID of an AWS WAF Regional rule (p. 2229) to associate with a web ACL.

Required: Yes

Type: String

AWS::WAFRegional::WebACLAssociation

The `AWS::WAFRegional::WebACLAssociation` resource associates an AWS WAF Regional web access control group (ACL) with a resource. For more information, see AssociateWebACL in the *AWS WAF Regional API Reference*.

Topics

- Syntax (p. 2247)
- Properties (p. 2247)
- Example (p. 2248)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAFRegional::WebACLAssociation",
  "Properties" : {
    "ResourceArn" : String,
    "WebACLId" : String
  }
}
```

YAML

```
Type: "AWS::WAFRegional::WebACLAssociation"
Properties:
  ResourceArn: String
  WebACLId: String
```

Properties

Note
For more information about constraints and values for each property, see AssociateWebACL in the *AWS WAF Regional API Reference*.

`ResourceArn`

The Amazon Resource Name (ARN) of the resource to protect with the web ACL.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`WebACLId`

A unique identifier (ID) for the web ACL.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

Example

The following example associates an Application load balancer resource with a web ACL.

JSON

```
"MyWebACLAssociation": {
  "Type": "AWS::WAFRegional::WebACLAssociation",
  "Properties": {
    "ResourceArn": { "Ref": "MyLoadBalancer" },
    "WebACLId": { "Ref": "MyWebACL" }
  }
}
```

YAML

```
MyWebACLAssociation:
  Type: "AWS::WAFRegional::WebACLAssociation"
  Properties:
    ResourceArn:
      Ref: MyLoadBalancer
    WebACLId:
      Ref: MyWebACL
```

AWS::WAFRegional::XssMatchSet

The `AWS::WAFRegional::XssMatchSet` resource specifies the parts of web requests that you want AWS WAF to inspect for cross-site scripting attacks and the name of the header to inspect. For more information, see XssMatchSet in the *AWS WAF Regional API Reference*.

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WAFRegional::XssMatchSet",
```

```
  "Properties" : {
    "Name" : String,
    "XssMatchTuples" : [ XssMatchTuple, ... ]
  }
}
```

YAML

```
Type: "AWS::WAFRegional::XssMatchSet"
Properties:
  Name: String
  XssMatchTuples:
    - XssMatchTuple
```

Properties

`Name`

A friendly name or description for the `XssMatchSet`.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`XssMatchTuples`

The parts of web requests that you want to inspect for cross-site scripting attacks.

Required: No

Type: List of AWS WAF Regional XssMatchSet XssMatchTuple (p. 2252)

Update requires: No interruption (p. 120)

Return Value

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource physical ID, such as `1234a1a-a1b1-12a1-abcd-a123b123456`.

For more information about using the `Ref` function, see Ref (p. 2341).

Examples

Define Which Part of a Request to Check for Cross-site Scripting

The following example looks for cross-site scripting in the URI or query string of an HTTP request.

JSON

```
"DetectXSS": {
  "Type": "AWS::WAFRegional::XssMatchSet",
  "Properties": {
    "Name": "XssMatchSet",
    "XssMatchTuples": [
      {
```

```
        "FieldToMatch": {
          "Type": "URI"
        },
        "TextTransformation": "NONE"
      },
      {
        "FieldToMatch": {
          "Type": "QUERY_STRING"
        },
        "TextTransformation": "NONE"
      }
    ]
  }
}
```

YAML

```
DetectXSS:
  Type: "AWS::WAFRegional::XssMatchSet"
  Properties:
    Name: "XssMatchSet"
    XssMatchTuples:
      -
        FieldToMatch:
          Type: "URI"
        TextTransformation: "NONE"
      -
        FieldToMatch:
          Type: "QUERY_STRING"
        TextTransformation: "NONE"
```

Associate an XssMatchSet with a Web ACL Rule

The following example associates the `DetectXSS` match set with a web access control list (ACL) rule.

JSON

```
"XSSRule" : {
  "Type": "AWS::WAFRegional::Rule",
  "Properties": {
    "Name": "XSSRule",
    "MetricName" : "XSSRule",
    "Predicates": [
      {
        "DataId" : {  "Ref" : "DetectXSS" },
        "Negated" : false,
        "Type" : "XssMatch"
      }
    ]
  }
}
```

YAML

```
XSSRule:
  Type: "AWS::WAFRegional::Rule"
  Properties:
    Name: "XSSRule"
    MetricName: "XSSRule"
    Predicates:
      -
```

```
        DataId:
          Ref: "DetectXSS"
        Negated: false
        Type: "XssMatch"
```

Create a Web ACL

The following example associates the `XSSRule` rule with a web ACL. The web ACL allows all requests except for ones that contain cross-site scripting in the URI or query string of an HTTP request.

JSON

```
"MyWebACL": {
  "Type": "AWS::WAFRegional::WebACL",
  "Properties": {
    "Name": "Web ACL to block cross-site scripting",
    "DefaultAction": {
      "Type": "ALLOW"
    },
    "MetricName" : "DetectXSSWebACL",
    "Rules": [
      {
        "Action" : {
          "Type" : "BLOCK"
        },
        "Priority" : 1,
        "RuleId" : { "Ref" : "XSSRule" }
      }
    ]
  }
}
```

YAML

```
MyWebACL:
  Type: "AWS::WAFRegional::WebACL"
  Properties:
    Name: "Web ACL to block cross-site scripting"
    DefaultAction:
      Type: "ALLOW"
    MetricName: "DetectXSSWebACL"
    Rules:
      -
        Action:
          Type: "BLOCK"
        Priority: 1
        RuleId:
          Ref: "XSSRule"
```

AWS WAF Regional XssMatchSet XssMatchTuple FieldToMatch

`FieldToMatch` is a property of the AWS WAF Regional XssMatchSet XssMatchTuple (p. 2252) property that specifies the part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Syntax

JSON

```
{
```

```
  "Data" : String,
  "Type" : String
}
```

YAML

```
Data: String
Type: String
```

Properties

`Data`

If you specify `HEADER` for the `Type` property, the name of the header that AWS WAF searches for, such as `User-Agent` or `Referer`. If you specify any other value for the `Type` property, do not specify this property.

Required: Conditional

Type: String

`Type`

The part of the web request in which AWS WAF searches for the target string. For valid values, see FieldToMatch in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

AWS WAF Regional XssMatchSet XssMatchTuple

`XssMatchTuple` is a property of the AWS::WAFRegional::XssMatchSet (p. 2248) resource that specifies the part of a web request that you want AWS WAF to inspect for cross-site scripting attacks.

Syntax

JSON

```
{
  "FieldToMatch" : Field to match,
  "TextTransformation" : String
}
```

YAML

```
FieldToMatch:
  Field to match
TextTransformation: String
```

Properties

`FieldToMatch`

The part of a web request that you want AWS WAF to search, such as a specific header or a query string.

Required: Yes

Type: AWS WAF Regional XssMatchSet XssMatchTuple FieldToMatch (p. 2251)

`TextTransformation`

Specifies how AWS WAF processes the `FieldToMatch` property before inspecting a request for a match. Text transformations eliminate some of the unusual formatting that attackers use in web requests in an effort to bypass AWS WAF. If you specify a transformation, AWS WAF transforms the`FieldToMatch` parameter before inspecting a web request for a match.

For example, AWS WAF can replace white space characters (such as `\t` and `\n`) with a single space. For valid values, see the `TextTransformation` content for the XssMatchTuple data type in the *AWS WAF Regional API Reference*.

Required: Yes

Type: String

Amazon WorkSpaces Resource Types Reference

This section contains reference information for all Amazon WorkSpaces resources that are supported by AWS CloudFormation.

Resource type identifiers always take the following form:

```
AWS::WorkSpaces::data-type-name
```

Topics

- AWS::WorkSpaces::Workspace (p. 2253)

AWS::WorkSpaces::Workspace

The `AWS::WorkSpaces::Workspace` resource creates an Amazon WorkSpaces workspace, which is a cloud-based desktop experience for end users. Before creating a Workspace in CloudFormation, you must register a Directory Service directory with Workspaces. This process is documented at Register a Directory with Amazon WorkSpaces. For more information, see the *Amazon WorkSpaces Administration Guide*.

Topics

- Syntax (p. 2253)
- Properties (p. 2254)
- Return Values (p. 2255)
- Example (p. 2255)

Syntax

To declare this entity in your AWS CloudFormation template, use the following syntax:

JSON

```
{
  "Type" : "AWS::WorkSpaces::Workspace",
  "Properties" : {
```

```
    "BundleId" : String,
    "DirectoryId" : String,
    "UserName" : String,
    "RootVolumeEncryptionEnabled" : Boolean,
    "UserVolumeEncryptionEnabled" : Boolean,
    "VolumeEncryptionKey" : String
  }
}
```

YAML

```
Type: "AWS::WorkSpaces::Workspace"
Properties:
  BundleId: String
  DirectoryId: String
  UserName: String
  RootVolumeEncryptionEnabled: Boolean
  UserVolumeEncryptionEnabled: Boolean
  VolumeEncryptionKey: String
```

Properties

`BundleId`

The identifier of the bundle from which you want to create the workspace. A bundle specifies the details of the workspace, such as the installed applications and the size of CPU, memory, and storage. Use the DescribeWorkspaceBundles action to list the bundles that AWS offers.

Required: Yes

Type: String

Update requires: Updates are not supported.. To update this property, you must also update another property that triggers a replacement, such as the `UserName` property.

`DirectoryId`

The identifier of the AWS Directory Service directory in which you want to create the workspace. The directory must already be registered with Amazon WorkSpaces. Use the DescribeWorkspaceDirectories action to list the directories that are available.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`UserName`

The name of the user to which the workspace is assigned. This user name must exist in the specified AWS Directory Service directory.

Required: Yes

Type: String

Update requires: Replacement (p. 121)

`RootVolumeEncryptionEnabled`

Indicates whether Amazon WorkSpaces encrypts data stored on the root volume (`C:` drive).

Required: No

Type: Boolean

Update requires: Updates are not supported.. To update this property, you must also update another property that triggers a replacement, such as the `UserName` property.

`UserVolumeEncryptionEnabled`

Indicates whether Amazon WorkSpaces encrypts data stored on the user volume (`D:` drive).

Required: No

Type: Boolean

Update requires: Updates are not supported.. To update this property, you must also update another property that triggers a replacement, such as the `UserName` property.

`VolumeEncryptionKey`

The AWS Key Management Service (AWS KMS) key ID that Amazon WorkSpaces uses to encrypt data stored on your workspace.

Required: No

Type: String

Update requires: Updates are not supported.. To update this property, you must also update another property that triggers a replacement, such as the `UserName` property.

Return Values

Ref

When the logical ID of this resource is provided to the `Ref` intrinsic function, `Ref` returns the resource name.

For more information about using the `Ref` function, see Ref (p. 2341).

Example

The following example creates a workspace for user `test`. The bundle and directory IDs are specified as parameters in the same template.

JSON

```
"workspace1" : {
  "Type" : "AWS::WorkSpaces::Workspace",
  "Properties" : {
    "BundleId" : {"Ref" : "BundleId"},
    "DirectoryId" : {"Ref" : "DirectoryId"},
    "UserName" : "test"
  }
}
```

YAML

```
workspace1:
```

```
  Type: "AWS::WorkSpaces::Workspace"
  Properties:
    BundleId:
      Ref: "BundleId"
    DirectoryId:
      Ref: "DirectoryId"
    UserName: "test"
```

Shared Property Types Reference

This section contains detailed reference information for property types that AWS CloudFormation supports for use in multiple resource types.

Topics

- Name Type (p. 2256)
- Resource Tag (p. 2258)

Name Type

For some resources, you can specify a custom name. By default, AWS CloudFormation generates a unique physical ID to name a resource. For example, AWS CloudFormation might name an Amazon S3 bucket with the following physical ID `stack123123123123-s3bucket-abcdefghijk1`. With custom names, you can specify a name that's easier to read and identify, such as `production-app-logs` or `business-metrics`.

Resource names must be unique across all of your active stacks. If you reuse templates to create multiple stacks, you must change or remove custom names from your template. If you don't specify a name, AWS CloudFormation generates a unique physical ID to name the resource. Names must begin with a letter; contain only ASCII letters, digits, and hyphens; and not end with a hyphen or contain two consecutive hyphens.

Also, do not manage stack resources outside of AWS CloudFormation. For example, if you rename a resource that's part of a stack without using AWS CloudFormation, you might get an error any time you try to update or delete that stack.

> **Important**
> You can't perform an update that causes a custom-named resource to be replaced. If you must replace the resource, specify a new name.

Example

If you want to use a custom name, specify a name property for that resource in your AWS CloudFormation template. Each resource that supports custom names has its own property that you specify. For example, to name an DynamoDB table, you use the `TableName` property, as shown in the following sample:

JSON

```
"myDynamoDBTable" : {
   "Type" : "AWS::DynamoDB::Table",
   "Properties" : {
      "KeySchema" : {
         "HashKeyElement": {
            "AttributeName" : "AttributeName1",
            "AttributeType" : "S"
         },
```

```
         "RangeKeyElement" : {
            "AttributeName" : "AttributeName2",
            "AttributeType" : "N"
         }
      },
      "ProvisionedThroughput" : {
         "ReadCapacityUnits" : "5",
         "WriteCapacityUnits" : "10"
      },
      "TableName" : "SampleTable"
   }
}
```

YAML

```
myDynamoDBTable:
  Type: AWS::DynamoDB::Table
  Properties:
    KeySchema:
      HashKeyElement:
        AttributeName: "AttributeName1"
        AttributeType: "S"
      RangeKeyElement:
        AttributeName: "AttributeName2"
        AttributeType: "N"
    ProvisionedThroughput:
      ReadCapacityUnits: "5"
      WriteCapacityUnits: "10"
    TableName: "SampleTable"
```

Supported Resources

The following resource types support custom names:

- AWS::ApiGateway::ApiKey (p. 536)
- AWS::ApiGateway::Model (p. 590)
- AWS::CloudWatch::Alarm (p. 874)
- AWS::DynamoDB::Table (p. 1115)
- AWS::ElasticBeanstalk::Application (p. 1425)
- AWS::ElasticBeanstalk::Environment (p. 1438)
- AWS::CodeDeploy::Application (p. 935)
- AWS::CodeDeploy::DeploymentConfig (p. 937)
- AWS::CodeDeploy::DeploymentGroup (p. 940)
- AWS::Config::ConfigRule (p. 1037)
- AWS::Config::DeliveryChannel (p. 1053)
- AWS::Config::ConfigurationRecorder (p. 1050)
- AWS::ElasticLoadBalancing::LoadBalancer (p. 1452)
- AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484)
- AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491)
- AWS::EC2::SecurityGroup (p. 1225)
- AWS::ElastiCache::CacheCluster (p. 1386)
- AWS::ECR::Repository (p. 1322)

- AWS::ECS::Cluster (p. 1327)
- AWS::Elasticsearch::Domain (p. 1412)
- AWS::Events::Rule (p. 882)
- AWS::IAM::Group (p. 1658)
- AWS::IAM::ManagedPolicy (p. 1662)
- AWS::IAM::Role (p. 1670)
- AWS::IAM::User (p. 1678)
- AWS::Lambda::Function (p. 1800)
- AWS::RDS::DBInstance (p. 1898)
- AWS::S3::Bucket (p. 1985)
- AWS::SNS::Topic (p. 2128)
- AWS::SQS::Queue (p. 2133)

Resource Tag

You can use the Resource Tags property to apply tags to resources, which can help you identify and categorize those resources. You can tag only resources for which AWS CloudFormation supports tagging. For information about which resources you can tag with AWS CloudFormation, see the individual resources in AWS Resource and Property Types Reference (p. 518).

> **Note**
> Tagging implementations might vary by resource. For example, AWS::AutoScaling::AutoScalingGroup provides an additional, required `PropagateAtLaunch` property as part of its tagging scheme.

In addition to any tags you define, AWS CloudFormation automatically creates the following stack-level tags with the prefix `aws:`:

- `aws:cloudformation:`*`logical-id`*
- `aws:cloudformation:`*`stack-id`*
- `aws:cloudformation:`*`stack-name`*

All stack-level tags, including automatically created tags, are propagated to resources that AWS CloudFormation supports. Currently, tags are not propagated to Amazon EBS volumes that are created from block device mappings.

Syntax

JSON

```
{
  "Key (p. 2259)" : String,
  "Value (p. 2259)" : String
}
```

YAML

```
Key (p. 2259): String
Value (p. 2259): String
```

Properties

`Key`

The key name of the tag. You can specify a value that is 1 to 127 Unicode characters in length and cannot be prefixed with `aws:`. You can use any of the following characters: the set of Unicode letters, digits, whitespace, _, `.`, /, =, +, and –.

Required: Yes

Type: String

`Value`

The value for the tag. You can specify a value that is 1 to 255 Unicode characters in length and cannot be prefixed with `aws:`. You can use any of the following characters: the set of Unicode letters, digits, whitespace, _, `.`, /, =, +, and –.

Required: Yes

Type: String

Example

This example shows a `Tags` property. You specify this property within the `Properties` section of a resource that supports it. When the resource is created, it is tagged with the tags you declare.

JSON

```
"Tags" : [
   {
      "Key" : "keyname1",
      "Value" : "value1"
   },
   {
      "Key" : "keyname2",
      "Value" : "value2"
   }
]
```

YAML

```
Tags:
  -
    Key: "keyname1"
    Value: "value1"
  -
    Key: "keyname2"
    Value: "value2"
```

AWS CloudFormation Resource Specification

The AWS CloudFormation resource specification is a JSON-formatted text file that defines the resources and properties that AWS CloudFormation supports. The document is a machine-readable, strongly

typed specification that you can use to build tools for creating AWS CloudFormation templates. For example, you can use the specification to build auto completion and validation functionality for AWS CloudFormation templates in your IDE (integrated development environment).

The resource specification is organized as both a single file and as a series of files, where each file contains the definition of one resource type. The single and separated files contain identical information. Depending on the tool and your implementation, use the file or files that work for you.

To download the resource specification, see the following table.

Resource availability may vary by region. To check the availability of a resource in a given region, refer to the resource specification for that region.

Resource Specification

Region	Single File	All Files
Asia Pacific (Mumbai)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
Asia Pacific (Osaka-Local)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
Asia Pacific (Seoul)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
Asia Pacific (Singapore)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
Asia Pacific (Sydney)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
Asia Pacific (Tokyo)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
Canada (Central)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
EU (Frankfurt)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
EU (Ireland)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
EU (London)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
EU (Paris)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
South America (São Paulo)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
US East (N. Virginia)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
US East (Ohio)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
US West (N. California)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip
US West (Oregon)	CloudFormationResourceSpecification.json	CloudFormationResourceSpecification.zip

The following example shows the specification for an AWS Key Management Service key resource (`AWS::KMS::Key`). It shows the properties for the `AWS::KMS::Key` resource, which properties are required, the type of allowed value for each property, and their update behavior. For details about the specification, see Specification Format (p. 2261).

```
    "AWS::KMS::Key": {
      "Attributes": {
        "Arn": {
          "PrimitiveType": "String"
        }
      },
      "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/aws-
resource-kms-key.html",
```

```
      "Properties": {
        "Description": {
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-resource-kms-key.html#cfn-kms-key-description",
          "PrimitiveType": "String",
          "Required": false,
          "UpdateType": "Mutable"
        },
        "EnableKeyRotation": {
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-resource-kms-key.html#cfn-kms-key-enablekeyrotation",
          "PrimitiveType": "Boolean",
          "Required": false,
          "UpdateType": "Mutable"
        },
        "Enabled": {
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-resource-kms-key.html#cfn-kms-key-enabled",
          "PrimitiveType": "Boolean",
          "Required": false,
          "UpdateType": "Mutable"
        },
        "KeyPolicy": {
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-resource-kms-key.html#cfn-kms-key-keypolicy",
          "PrimitiveType": "Json",
          "Required": true,
          "UpdateType": "Mutable"
        },
        "KeyUsage": {
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-resource-kms-key.html#cfn-kms-key-keyusage",
          "PrimitiveType": "String",
          "Required": false,
          "UpdateType": "Immutable"
        }
      }
    }
```

Specification Format

AWS CloudFormation creates a specification for each resource type (p. 518), such as `AWS::S3::Bucket` or `AWS::EC2::Instance`. The following sections describe the format and each field within the specification.

Topics

- Specification Sections (p. 2261)
- Property Specification (p. 2262)
- Resource Specification (p. 2263)
- Example Resource Specification (p. 2264)

Specification Sections

The formal definition for each resource type is organized into three main sections: `PropertyTypes`, `ResourceSpecificationVersion`, and `ResourceTypes`, as shown in the following example:

```
{
  "PropertyTypes": {
    Property specifications (p. 2262)
```

```
  },
  "ResourceSpecificationVersion": "Specification version number",
  "ResourceTypes": {
    Resource specification (p. 2263)
  }
}
```

`PropertyTypes`

For resources that have properties within a property (also known as subproperties), a list of subproperty specifications, such as which properties are required, the type of allowed value for each property, and their update behavior. For more information, see Property Specification (p. 2262).

If a resource doesn't have subproperties, this section is omitted.

`ResourceSpecificationVersion`

The version of the resource specification. The version format is *`majorVersion`*`.`*`minorVersion`*`.`*`patch`*, where each release increments the version number. All resources have the same version number regardless of whether the resource was updated.

AWS CloudFormation increments the patch number when the service makes a backwards-compatible bug fix, such as fixing a broken documentation link. When AWS CloudFormation adds resources or properties that are backwards compatible, it increments the minor version number. For example, later versions of a specification might add additional resource properties to support new features of an AWS service.

Backwards incompatible changes increment the major version number. A backwards incompatible change can result from a change in the resource specification, such as a name change to a field, or a change to a resource, such as the making an optional resource property required.

`ResourceTypes`

The list of resources and information about each resource's properties, such as its property names, which properties are required, and their update behavior. For more information, see Resource Specification (p. 2263).

> **Note**
> If you view a file that contains the definition of one resource type, this property name is `ResourceType` (singular).

Property Specification

The specification for each property includes the following fields. For subproperties, the property name uses the *`resourceType`*`.`*`subpropertyName`* format.

```
"Property name": {
  "Documentation": "Link to the relevant documentation"
  "DuplicatesAllowed": "true or false",
  "ItemType": "Type of list or map (non-primitive)",
  "PrimitiveItemType": "Type of list or map (primitive)",
  "PrimitiveType": "Type of value (primitive)",
  "Required": "true or false",
  "Type": "Type of value (non-primitive)",
  "UpdateType": "Mutable, Immutable, or Conditional",
}
```

`Documentation`

A link to the *AWS CloudFormation User Guide* that provides information about the property.

`DuplicatesAllowed`

If the value of the `Type` field is `List`, indicates whether AWS CloudFormation allows duplicate values. If the value is `true`, AWS CloudFormation ignores duplicate values. If the value is `false`, AWS CloudFormation returns an error if you submit duplicate values.

`ItemType`

If the value of the `Type` field is `List` or `Map`, indicates the type of list or map if they contain non-primitive types. Otherwise, this field is omitted. For lists or maps that contain primitive types, the `PrimitiveItemType` property indicates the valid value type.

A subproperty name is a valid item type. For example, if the type value is `List` and the item type value is `PortMapping`, you can specify a list of port mapping properties.

`PrimitiveItemType`

If the value of the `Type` field is `List` or `Map`, indicates the type of list or map if they contain primitive types. Otherwise, this field is omitted. For lists or maps that contain non-primitive types, the `ItemType` property indicates the valid value type.

The valid primitive types for lists and maps are `String`, `Long`, `Integer`, `Double`, `Boolean`, or `Timestamp`.

For example, if the type value is `List` and the item type value is `String`, you can specify a list of strings for the property. If the type value is `Map` and the item type value is `Boolean`, you can specify a string to Boolean mapping for the property.

`PrimitiveType`

For primitive values, the valid primitive type for the property. A primitive type is a basic data type for resource property values. The valid primitive types are `String`, `Long`, `Integer`, `Double`, `Boolean`, `Timestamp` or `Json`. If valid values are a non-primitive type, this field is omitted and the `Type` field indicates the valid value type.

`Required`

Indicates whether the property is required.

`Type`

For non-primitive types, valid values for the property. The valid types are a subproperty name, `List` or `Map`. If valid values are a primitive type, this field is omitted and the `PrimitiveType` field indicates the valid value type.

A list is a comma-separated list of values. A map is a set of key-value pairs, where the keys are always strings. The value type for lists and maps are indicated by the `ItemType` or `PrimitiveItemType` field.

`UpdateType`

During a stack update, the update behavior when you add, remove, or modify the property. AWS CloudFormation replaces the resource when you change `Immutable` properties. AWS CloudFormation doesn't replace the resource when you change `mutable` properties. Conditional updates can be mutable or immutable, depending on, for example, which other properties you updated. For more information, see the relevant resource type (p. 518) documentation.

Resource Specification

The specification for each resource type includes the following fields.

```
"Resource type name": {
```

```
  "Attributes": {
    "AttributeName": {
      "ItemType": "Return list or map type (non-primitive)",
      "PrimitiveItemType": "Return list or map type (primitive)",
      "PrimitiveType": "Return value type (primitive)",
      "Type": "Return value type (non-primitive)",
    }
  },
  "Documentation": "Link to the relevant documentation",
  "Properties": {
    Property specifications (p. 2262)
  }
}
```

`Attributes`

A list of resource attributes that you can use in an `Fn::GetAtt` (p. 2313) function. For each attribute, this section provides the attribute name and the type of value that AWS CloudFormation returns.

`ItemType`

If the value of the `Type` field is `List`, indicates the type of list that the `Fn::GetAtt` function returns for the attribute if the list contains non-primitive types. The valid type is a name of a property.

`PrimitiveItemType`

If the value of the `Type` field is `List`, indicates the type of list that the `Fn::GetAtt` function returns for the attribute if the list contains primitive types. For lists that contain non-primitive types, the `ItemType` property indicates the valid value type. The valid primitive types for lists are `String`, `Long`, `Integer`, `Double`, `Boolean`, or `Timestamp`.

For example, if the type value is `List` and the primitive item type value is `String`, the `Fn::GetAtt` function returns a list of strings.

`PrimitiveType`

For primitive return values, the type of primitive value that the `Fn::GetAtt` function returns for the attribute. A primitive type is a basic data type for resource property values. The valid primitive types are `String`, `Long`, `Integer`, `Double`, `Boolean`, `Timestamp` or `Json`.

`Type`

For non-primitive return values, the type of value that the `Fn::GetAtt` function returns for the attribute. The valid types are a property name or `List`.

A list is a comma-separated list of values. The value type for lists are indicated by the `ItemType` or `PrimitiveItemType` field.

`Documentation`

A link to the *AWS CloudFormation User Guide* for information about the resource.

`Properties`

A list of property specifications for the resource. For details, see Property Specification (p. 2262).

Example Resource Specification

The following examples highlight and explain parts of the `AWS::Elasticsearch::Domain` (p. 1412) resource specification.

The `AWS::Elasticsearch::Domain` resource type contains subproperties, so the specification includes a `PropertyTypes` section. This section is followed by the `ResourceSpecificationVersion` section, which shows the specification version as `1.0.0`. After the specification version is the `ResourceType` section that specifies the resource type, provides a documentation link, and details the resource's properties.

```
{
  "PropertyTypes": {
    ...

  },
  "ResourceSpecificationVersion": "1.0.0",
  "ResourceType": {
    "AWS::Elasticsearch::Domain": {
      "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/aws-
resource-elasticsearch-domain.html",
      "Properties": {
        ...

        }
      }
    }
  }
}
```

Focusing on the `ResourceType` section, the following example shows two properties of the `AWS::Elasticsearch::Domain` resource type. The `AdvancedOptions` property is not required and accepts a string to string map. A map is a collection of key-value pairs, where the keys are always strings. The value type is indicated by the `ItemType` field, which is `String`. Therefore, the type is a string to string map. The update behavior for this property is mutable. If update this property, AWS CloudFormation keeps the resource instead of creating a new one and then deleting the old one (an immutable update).

The `SnapshotOptions` property is not required and accepts a subproperty named `SnapshotOptions`. Details of the `SnapshotOptions` subproperty is provided in the `PropertyTypes` section.

```
{
  "PropertyTypes": {
    ...

  },
  "ResourceSpecificationVersion": "1.0.0",
  "ResourceType": {
    "AWS::Elasticsearch::Domain": {
      "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/aws-
resource-elasticsearch-domain.html",
      "Properties": {
        ...

        "AdvancedOptions": {
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-resource-elasticsearch-domain.html#cfn-elasticsearch-domain-advancedoptions",
          "DuplicatesAllowed": false,
          "PrimitiveItemType": "String",
          "Required": false,
          "Type": "Map",
          "UpdateType": "Mutable"
        },
        ...

        "SnapshotOptions": {
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-resource-elasticsearch-domain.html#cfn-elasticsearch-domain-snapshotoptions",
```

```
          "Required": false,
          "Type": "SnapshotOptions",
          "UpdateType": "Mutable"
        },
        ...

      }
    }
  }
}
```

In the `PropertyTypes`, the specification lists all of the subproperties of a resource (including nested subproperties). The following example details the `AWS::Elasticsearch::Domain.SnapshotOptions` subproperty. It contains one property named `AutomatedSnapshotStartHour`, which is not required and accepts integer value types.

```
"PropertyTypes": {
  ...

  "AWS::Elasticsearch::Domain.SnapshotOptions": {
    "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/aws-
properties-elasticsearch-domain-snapshotoptions.html",
    "Properties": {
      "AutomatedSnapshotStartHour": {
        "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-properties-elasticsearch-domain-snapshotoptions.html#cfn-elasticsearch-domain-
snapshotoptions-automatedsnapshotstarthour",
        "PrimitiveType": "Integer",
        "Required": false,
        "UpdateType": "Mutable"
      }
    }
  },
  ...

}
```

For your reference, the following example provides the entire `AWS::Elasticsearch::Domain` resource specification.

```
{
  "PropertyTypes": {
    "AWS::Elasticsearch::Domain.EBSOptions": {
      "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/aws-
properties-elasticsearch-domain-ebsoptions.html",
      "Properties": {
        "EBSEnabled": {
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-properties-elasticsearch-domain-ebsoptions.html#cfn-elasticsearch-domain-ebsoptions-
ebsenabled",
          "PrimitiveType": "Boolean",
          "Required": false,
          "UpdateType": "Mutable"
        },
        "Iops": {
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-properties-elasticsearch-domain-ebsoptions.html#cfn-elasticsearch-domain-ebsoptions-
iops",
          "PrimitiveType": "Integer",
          "Required": false,
          "UpdateType": "Mutable"
        },
        "VolumeSize": {
```

```
          "Documentation": "http://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/
aws-properties-elasticsearch-domain-ebsoptions.html#cfn-elasticsearch-domain-ebsoptions-
volumesize",
          "PrimitiveType": "Integer",

Resource Attribute Reference

This section details the attributes that you can add to a resource to control additional behaviors and relationships.

Topics

- CreationPolicy Attribute (p. 2270)

- DeletionPolicy Attribute (p. 2273)
- DependsOn Attribute (p. 2275)
- Metadata Attribute (p. 2280)
- UpdatePolicy Attribute (p. 2281)

CreationPolicy Attribute

Associate the `CreationPolicy` attribute with a resource to prevent its status from reaching create complete until AWS CloudFormation receives a specified number of success signals or the timeout period is exceeded. To signal a resource, you can use the cfn-signal (p. 2361) helper script or `SignalResource` API. AWS CloudFormation publishes valid signals to the stack events so that you track the number of signals sent.

The creation policy is invoked only when AWS CloudFormation creates the associated resource. Currently, the only AWS CloudFormation resources that support creation policies are AWS::AutoScaling::AutoScalingGroup (p. 699), AWS::EC2::Instance (p. 1155), and AWS::CloudFormation::WaitCondition (p. 827).

Use the `CreationPolicy` attribute when you want to wait on resource configuration actions before stack creation proceeds. For example, if you install and configure software applications on an EC2 instance, you might want those applications to be running before proceeding. In such cases, you can add a `CreationPolicy` attribute to the instance, and then send a success signal to the instance after the applications are installed and configured. For a detailed example, see Deploying Applications on Amazon EC2 with AWS CloudFormation (p. 262).

Syntax

JSON

```
"CreationPolicy" : {
  "AutoScalingCreationPolicy" : {
    "MinSuccessfulInstancesPercent" : Integer
  },
  "ResourceSignal" : {
    "Count" : Integer,
    "Timeout" : String
  }
}
```

YAML

```
CreationPolicy:
  AutoScalingCreationPolicy:
    MinSuccessfulInstancesPercent: Integer
  ResourceSignal:
    Count: Integer
    Timeout: String
```

CreationPolicy Properties

`AutoScalingCreationPolicy`

For an Auto Scaling group replacement update (p. 2281), specifies how many instances must signal success for the update to succeed.

`MinSuccessfulInstancesPercent`

Specifies the percentage of instances in an Auto Scaling replacement update that must signal success for the update to succeed. You can specify a value from `0` to `100`. AWS CloudFormation rounds to the nearest tenth of a percent. For example, if you update five instances with a minimum successful percentage of `50`, three instances must signal success. If an instance doesn't send a signal within the time specified by the `Timeout` property, AWS CloudFormation assumes that the instance wasn't created.

Default: `100`

Type: Integer

Required: No

`ResourceSignal`

When AWS CloudFormation creates the associated resource, configures the number of required success signals and the length of time that AWS CloudFormation waits for those signals.

`Count`

The number of success signals AWS CloudFormation must receive before it sets the resource status as `CREATE_COMPLETE`. If the resource receives a failure signal or doesn't receive the specified number of signals before the timeout period expires, the resource creation fails and AWS CloudFormation rolls the stack back.

Default: `1`

Type: Integer

Required: No

`Timeout`

The length of time that AWS CloudFormation waits for the number of signals that was specified in the `Count` property. The timeout period starts after AWS CloudFormation starts creating the resource, and the timeout expires no sooner than the time you specify but can occur shortly thereafter. The maximum time that you can specify is 12 hours.

The value must be in ISO8601 duration format, in the form: "PT#H#M#S", where each # is the number of hours, minutes, and seconds, respectively. For best results, specify a period of time that gives your instances plenty of time to get up and running. A shorter timeout can cause a rollback.

Default: `PT5M` (5 minutes)

Type: String

Required: No

Examples

Auto Scaling Group

The following example shows how to add a creation policy to an Auto Scaling group. The creation policy requires three success signals and times out after 15 minutes.

To have instances wait for an Elastic Load Balancing health check before they signal success, add a health-check verification by using the cfn-init helper script. For an example, see the `verify_instance_health` command in the Auto Scaling rolling updates sample template.

JSON

```
"AutoScalingGroup": {
  "Type": "AWS::AutoScaling::AutoScalingGroup",
  "Properties": {
    "AvailabilityZones": { "Fn::GetAZs": "" },
    "LaunchConfigurationName": { "Ref": "LaunchConfig" },
    "DesiredCapacity": "3",
    "MinSize": "1",
    "MaxSize": "4"
  },
  "CreationPolicy": {
    "ResourceSignal": {
      "Count": "3",
      "Timeout": "PT15M"
    }
  },
  "UpdatePolicy" : {
    "AutoScalingScheduledAction" : {
      "IgnoreUnmodifiedGroupSizeProperties" : "true"
    },
    "AutoScalingRollingUpdate" : {
      "MinInstancesInService" : "1",
      "MaxBatchSize" : "2",
      "PauseTime" : "PT1M",
      "WaitOnResourceSignals" : "true"
    }
  }
},
"LaunchConfig": {
  "Type": "AWS::AutoScaling::LaunchConfiguration",
  "Properties": {
    "ImageId": "ami-16d18a7e",
    "InstanceType": "t2.micro",
    "UserData": {
      "Fn::Base64": {
        "Fn::Join" : [ "", [
          "#!/bin/bash -xe\n",
          "yum install -y aws-cfn-bootstrap\n",
          "/opt/aws/bin/cfn-signal -e 0 --stack ", { "Ref": "AWS::StackName" },
          " --resource AutoScalingGroup ",
          " --region ", { "Ref" : "AWS::Region" }, "\n"
        ] ]
      }
    }
  }
}
```

YAML

```
AutoScalingGroup:
  Type: AWS::AutoScaling::AutoScalingGroup
  Properties:
    AvailabilityZones:
      Fn::GetAZs: ''
    LaunchConfigurationName:
      Ref: LaunchConfig
    DesiredCapacity: '3'
    MinSize: '1'
    MaxSize: '4'
  CreationPolicy:
    ResourceSignal:
      Count: '3'
      Timeout: PT15M
```

```
  UpdatePolicy:
    AutoScalingScheduledAction:
      IgnoreUnmodifiedGroupSizeProperties: 'true'
    AutoScalingRollingUpdate:
      MinInstancesInService: '1'
      MaxBatchSize: '2'
      PauseTime: PT1M
      WaitOnResourceSignals: 'true'
LaunchConfig:
  Type: AWS::AutoScaling::LaunchConfiguration
  Properties:
    ImageId: ami-16d18a7e
    InstanceType: t2.micro
    UserData:
      "Fn::Base64":
        !Sub |
          #!/bin/bash -xe
          yum update -y aws-cfn-bootstrap
          /opt/aws/bin/cfn-signal -e $? --stack ${AWS::StackName} --resource
 AutoScalingGroup --region ${AWS::Region}
```

WaitCondition

The following example shows how to add a creation policy to a wait condition.

JSON

```
"WaitCondition" : {
    "Type" : "AWS::CloudFormation::WaitCondition",
    "CreationPolicy" : {
        "ResourceSignal" : {
            "Timeout" : "PT15M",
            "Count" : "5"
        }
    }
}
```

YAML

```
WaitCondition:
  Type: AWS::CloudFormation::WaitCondition
  CreationPolicy:
    ResourceSignal:
      Timeout: PT15M
      Count: 5
```

DeletionPolicy Attribute

With the DeletionPolicy attribute you can preserve or (in some cases) backup a resource when its stack is deleted. You specify a DeletionPolicy attribute for each resource that you want to control. If a resource has no DeletionPolicy attribute, AWS CloudFormation deletes the resource by default.

Note that this capability also applies to stack update operations that lead to resources being deleted from stacks. For example, if you remove the resource from the stack template, and then update the stack with the template. This capability does not apply to resources whose physical instance is replaced during stack update operations. For example, if you edit a resource's properties such that AWS CloudFormation replaces that resource during a stack update.

> **Note**
> **Exception**: The default policy is `Snapshot` for `AWS::RDS::DBCluster` resources and for `AWS::RDS::DBInstance` resources that don't specify the `DBClusterIdentifier` property.

To keep a resource when its stack is deleted, specify `Retain` for that resource. You can use retain for any resource. For example, you can retain a nested stack, Amazon S3 bucket, or EC2 instance so that you can continue to use or modify those resources after you delete their stacks.

> **Note**
> If you want to modify resources outside of AWS CloudFormation, use a retain policy and then delete the stack. Otherwise, your resources might get out of sync with your AWS CloudFormation template and cause stack errors.

For resources that support snapshots, such as `AWS::EC2::Volume`, specify `Snapshot` to have AWS CloudFormation create a snapshot before deleting the resource.

The following snippet contains an Amazon S3 bucket resource with a `Retain` deletion policy. When this stack is deleted, AWS CloudFormation leaves the bucket without deleting it.

JSON

```
{
  "AWSTemplateFormatVersion" : "2010-09-09",
  "Resources" : {
    "myS3Bucket" : {
      "Type" : "AWS::S3::Bucket",
      "DeletionPolicy" : "Retain"
    }
  }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  myS3Bucket:
    Type: AWS::S3::Bucket
    DeletionPolicy: Retain
```

DeletionPolicy Options

Delete

AWS CloudFormation deletes the resource and all its content if applicable during stack deletion. You can add this deletion policy to any resource type. By default, if you don't specify a DeletionPolicy, AWS CloudFormation deletes your resources. However, be aware of the following considerations:

- For `AWS::RDS::DBCluster` resources, the default policy is `Snapshot`.
- For `AWS::RDS::DBInstance` resources that don't specify the `DBClusterIdentifier` property, the default policy is `Snapshot`.
- For Amazon S3 buckets, you must delete all objects in the bucket for deletion to succeed.

Retain

AWS CloudFormation keeps the resource without deleting the resource or its contents when its stack is deleted. You can add this deletion policy to any resource type. Note that when AWS CloudFormation completes the stack deletion, the stack will be in `Delete_Complete` state; however, resources that are retained continue to exist and continue to incur applicable charges until you delete those resources.

For update operations, the following considerations apply:

- If a resource is deleted, the DeletionPolicy retains the physical resource but ensures that it's deleted from AWS CloudFormation's scope.

- If a resource is updated such that a new physical resource is created to replace the old resource, then the old resource is completely deleted, including from AWS CloudFormation's scope.

Snapshot

For resources that support snapshots (`AWS::EC2::Volume`, `AWS::ElastiCache::CacheCluster`, `AWS::ElastiCache::ReplicationGroup`, `AWS::RDS::DBInstance`, `AWS::RDS::DBCluster`, and `AWS::Redshift::Cluster`), AWS CloudFormation creates a snapshot for the resource before deleting it. Note that when AWS CloudFormation completes the stack deletion, the stack will be in the `Delete_Complete` state; however, the snapshots that are created with this policy continue to exist and continue to incur applicable charges until you delete those snapshots.

DependsOn Attribute

With the `DependsOn` attribute you can specify that the creation of a specific resource follows another. When you add a `DependsOn` attribute to a resource, that resource is created only after the creation of the resource specified in the `DependsOn` attribute.

Important
Dependent stacks also have implicit dependencies. For example, if the properties of resource A use a `!Ref` to resource B, the following rule apply:

- Resource B is created before resource A.
- Resource A is deleted before resource B.

You can use the `DependsOn` attribute with any resource. Here are some typical uses:

- Determine when a wait condition goes into effect. For more information, see Creating Wait Conditions in a Template (p. 280).
- Declare dependencies for resources that must be created or deleted in a specific order. For example, you must explicitly declare dependencies on gateway attachments for some resources in a VPC. For more information, see When a DependsOn attribute is required (p. 2277).
- Override default parallelism when creating, updating, or deleting resources. AWS CloudFormation creates, updates, and deletes resources in parallel to the extent possible. It automatically determines which resources in a template can be parallelized and which have dependencies that require other operations to finish first. You can use `DependsOn` to explicitly specify dependencies, which overrides the default parallelism and directs CloudFormation to operate on those resources in a specified order.

Note
During a stack update, resources that depend on updated resources are updated automatically. AWS CloudFormation makes no changes to the automatically-updated resources, but, if a stack policy is associated with these resources, your account must have the permissions to update them.

Syntax

The `DependsOn` attribute can take a single string or list of strings.

```
"DependsOn" : [ String, ... ]
```

Example

The following template contains an AWS::EC2::Instance (p. 1155) resource with a `DependsOn` attribute that specifies myDB, an AWS::RDS::DBInstance (p. 1898). When AWS CloudFormation creates this stack, it first creates myDB, then creates Ec2Instance.

```

When a DependsOn attribute is required

VPC-gateway attachment

Some resources in a VPC require a gateway (either an Internet or VPN gateway). If your AWS CloudFormation template defines a VPC, a gateway, and a gateway attachment, any resources that require the gateway are dependent on the gateway attachment. For example, an Amazon EC2 instance with a public IP address is dependent on the VPC-gateway attachment if the `VPC` and `InternetGateway` resources are also declared in the same template.

Currently, the following resources depend on a VPC-gateway attachment when they have an associated public IP address and are in a VPC:

- Auto Scaling groups
- Amazon EC2 instances
- Elastic Load Balancing load balancers
- Elastic IP addresses
- Amazon RDS database instances
- Amazon VPC routes that include the Internet gateway

A VPN gateway route propagation depends on a VPC-gateway attachment when you have a VPN gateway.

The following snippet shows a sample gateway attachment and an Amazon EC2 instance that depends on a gateway attachment:

JSON

```
"GatewayToInternet" : {
  "Type" : "AWS::EC2::VPCGatewayAttachment",
  "Properties" : {
    "VpcId" : {
      "Ref" : "VPC"
```

```
    },
    "InternetGatewayId" : {
      "Ref" : "InternetGateway"
    }
  }
},

"EC2Host" : {
  "Type" : "AWS::EC2::Instance",

      SubnetId:
        Ref: PublicSubnet
```

Amazon ECS Service and Auto Scaling Group

When you use Auto Scaling or Amazon Elastic Compute Cloud (Amazon EC2) to create container instances for an Amazon ECS cluster, the Amazon ECS service resource must have a dependency on the Auto Scaling group or Amazon EC2 instances, as shown in the following snippet. That way the container instances are available and associated with the Amazon ECS cluster before AWS CloudFormation creates the Amazon ECS service.

JSON

```
"service": {
  "Type": "AWS::ECS::Service",
  "DependsOn": [
    "ECSAutoScalingGroup"
  ],
  "Properties" : {
    "Cluster": {
      "Ref": "ECSCluster"
    },
    "DesiredCount": "1",
    "LoadBalancers": [
      {
        "ContainerName": "simple-app",
        "ContainerPort": "80",
        "LoadBalancerName" : {
          "Ref" : "EcsElasticLoadBalancer"
        }
      }
    ],
    "Role" : {
      "Ref":"ECSServiceRole"
    },
    "TaskDefinition" : {
      "Ref":"taskdefinition"
    }
  }
}
```

YAML

```
service:
```

```
  Type: AWS::ECS::Service
  DependsOn:
  - ECSAutoScalingGroup
  Properties:
    Cluster:
      Ref: ECSCluster
    DesiredCount: 1
    LoadBalancers:
    - ContainerName: simple-app
      ContainerPort: 80
      LoadBalancerName:
        Ref: EcsElasticLoadBalancer
    Role:
      Ref: ECSServiceRole
    TaskDefinition:
      Ref: taskdefinition
```

IAM Role Policy

Resources that make additional calls to AWS require a service role, which permits a service to make calls to AWS on your behalf. For example, the `AWS::CodeDeploy::DeploymentGroup` resource requires a service role so that AWS CodeDeploy has permissions to deploy applications to your instances. When you have a single template that defines a service role, the role's policy (by using the `AWS::IAM::Policy` or `AWS::IAM::ManagedPolicy` resource), and a resource that uses the role, add a dependency so that the resource depends on the role's policy. This dependency ensures that the policy is available throughout the resource's lifecycle.

For example, imagine that you have a template with a deployment group resource, a service role, and the role's policy. When you create a stack, AWS CloudFormation won't create the deployment group until it creates the role's policy. Without the dependency, AWS CloudFormation can create the deployment group resource before it creates the role's policy. If that happens, the deployment group will fail to create because of insufficient permissions.

If the role has an embedded policy, don't specify a dependency. AWS CloudFormation creates the role and its policy at the same time.

Metadata Attribute

The Metadata attribute enables you to associate structured data with a resource. By adding a Metadata attribute to a resource, you can add data in JSON or YAML to the resource declaration. In addition, you can use intrinsic functions (such as GetAtt (p. 2313) and Ref (p. 2341)), parameters, and pseudo parameters within the Metadata attribute to add those interpreted values.

> **Note**
> AWS CloudFormation does not validate the syntax within the Metadata attribute.

You can retrieve this data using the AWS command `aws cloudformation describe-stack-resource` or the DescribeStackResource action.

Example

The following template contains an Amazon S3 bucket resource with a Metadata attribute.

JSON

```
{
   "AWSTemplateFormatVersion" : "2010-09-09",
   "Resources" : {
      "MyS3Bucket" : {
```

```
        "Type" : "AWS::S3::Bucket",
        "Metadata" : {
           "Object1" : "Location1",
           "Object2" : "Location2"
        }
     }
   }
}
```

YAML

```
AWSTemplateFormatVersion: '2010-09-09'
Resources:
  MyS3Bucket:
    Type: AWS::S3::Bucket
    Metadata:
      Object1: Location1
      Object2: Location2
```

UpdatePolicy Attribute

Use the `UpdatePolicy` attribute to specify how AWS CloudFormation handles updates to the `AWS::AutoScaling::AutoScalingGroup` or `AWS::Lambda::Alias` resource.

For `AWS::AutoScaling::AutoScalingGroup` resources, AWS CloudFormation invokes one of three update policies depending on the type of change you make or whether a scheduled action is associated with the Auto Scaling group.

- The `AutoScalingReplacingUpdate` and `AutoScalingRollingUpdate` policies apply *only* when you do one or more of the following:
  - Change the Auto Scaling group's `AWS::AutoScaling::LaunchConfiguration`.
  - Change the Auto Scaling group's `VPCZoneIdentifier` property
  - Change the Auto Scaling group's `LaunchTemplate` property
  - Update an Auto Scaling group that contains instances that don't match the current `LaunchConfiguration`.

  If both the `AutoScalingReplacingUpdate` and `AutoScalingRollingUpdate` policies are specified, setting the `WillReplace` property to `true` gives `AutoScalingReplacingUpdate` precedence.
- The `AutoScalingScheduledAction` policy applies when you update a stack that includes an Auto Scaling group with an associated scheduled action.

For `AWS::Lambda::Alias` resources, AWS CloudFormation performs an AWS CodeDeploy deployment when the version changes on the alias. For more information, see CodeDeployLambdaAliasUpdate Policy (p. 2285).

AutoScalingReplacingUpdate Policy

To specify how AWS CloudFormation handles replacement updates for an Auto Scaling group, use the `AutoScalingReplacingUpdate` policy. This policy enables you to specify whether AWS CloudFormation replaces an Auto Scaling group with a new one or replaces only the instances in the Auto Scaling group.

> **Important**
> Before attempting an update, ensure that you have sufficient Amazon EC2 capacity for both your old and new Auto Scaling groups.

Syntax

JSON

```
"UpdatePolicy" : {
  "AutoScalingReplacingUpdate (p. 2281)" : {
    "WillReplace" : Boolean
  }
}
```

YAML

```
UpdatePolicy:
  AutoScalingReplacingUpdate (p. 2281):
    WillReplace: Boolean
```

Properties

`WillReplace`

Specifies whether an Auto Scaling group and the instances it contains are replaced during an update. During replacement, AWS CloudFormation retains the old group until it finishes creating the new one. If the update fails, AWS CloudFormation can roll back to the old Auto Scaling group and delete the new Auto Scaling group.

While AWS CloudFormation creates the new group, it doesn't detach or attach any instances. After successfully creating the new Auto Scaling group, AWS CloudFormation deletes the old Auto Scaling group during the cleanup process.

When you set the `WillReplace` parameter, remember to specify a matching `CreationPolicy`. If the minimum number of instances (specified by the `MinSuccessfulInstancesPercent` property) don't signal success within the `Timeout` period (specified in the `CreationPolicy` policy), the replacement update fails and AWS CloudFormation rolls back to the old Auto Scaling group.

Type: Boolean

Required: No

AutoScalingRollingUpdate Policy

To specify how AWS CloudFormation handles rolling updates for an Auto Scaling group, use the `AutoScalingRollingUpdate` policy. Rolling updates enable you to specify whether AWS CloudFormation updates instances that are in an Auto Scaling group in batches or all at once.

> **Important**
> During a rolling update, some Auto Scaling processes might make changes to the Auto Scaling group before AWS CloudFormation completes the rolling update. These changes might cause the rolling update to fail. To prevent Auto Scaling from running processes during a rolling update, use the `SuspendProcesses` property. For more information, see What are some recommended best practices for performing Auto Scaling group rolling updates?

Syntax

JSON

```
"UpdatePolicy" : {
  "AutoScalingRollingUpdate (p. 2282)" : {
```

```
    "MaxBatchSize" : Integer,
    "MinInstancesInService" : Integer,
    "MinSuccessfulInstancesPercent" : Integer
    "PauseTime" : String,
    "SuspendProcesses" : [ List of processes ],
    "WaitOnResourceSignals" : Boolean
  }
}
```

YAML

```
UpdatePolicy:
  AutoScalingRollingUpdate (p. 2282):
    MaxBatchSize: Integer
    MinInstancesInService: Integer
    MinSuccessfulInstancesPercent: Integer
    PauseTime: String
    SuspendProcesses:
      - List of processes
    WaitOnResourceSignals: Boolean
```

Properties

`MaxBatchSize`

Specifies the maximum number of instances that AWS CloudFormation updates.

Default: `1`

Type: Integer

Required: No

`MinInstancesInService`

Specifies the minimum number of instances that must be in service within the Auto Scaling group while AWS CloudFormation updates old instances. This value must be less than the MaxSize of the Auto Scaling group.

Default: `0`

Type: Integer

Required: No

`MinSuccessfulInstancesPercent`

Specifies the percentage of instances in an Auto Scaling rolling update that must signal success for an update to succeed. You can specify a value from `0` to `100`. AWS CloudFormation rounds to the nearest tenth of a percent. For example, if you update five instances with a minimum successful percentage of `50`, three instances must signal success.

If an instance doesn't send a signal within the time specified in the `PauseTime` property, AWS CloudFormation assumes that the instance wasn't updated.

If you specify this property, you must also enable the `WaitOnResourceSignals` and `PauseTime` properties.

Default: `100`

Type: Integer

Required: No

`PauseTime`

The amount of time that AWS CloudFormation pauses after making a change to a batch of instances to give those instances time to start software applications. For example, you might need to specify `PauseTime` when scaling up the number of instances in an Auto Scaling group.

If you enable the `WaitOnResourceSignals` property, `PauseTime` is the amount of time that AWS CloudFormation should wait for the Auto Scaling group to receive the required number of valid signals from added or replaced instances. If the `PauseTime` is exceeded before the Auto Scaling group receives the required number of signals, the update fails. For best results, specify a time period that gives your applications sufficient time to get started. If the update needs to be rolled back, a short `PauseTime` can cause the rollback to fail.

Specify `PauseTime` in the ISO8601 duration format (in the format `PT#H#M#S`, where each `#` is the number of hours, minutes, and seconds, respectively). The maximum `PauseTime` is one hour (`PT1H`).

Default: `PT0S` (zero seconds). If the `WaitOnResourceSignals` property is set to `true`, the default is `PT5M`.

Type: String

Required: No

`SuspendProcesses`

Specifies the Auto Scaling processes to suspend during a stack update. Suspending processes prevents Auto Scaling from interfering with a stack update. For example, you can suspend alarming so that Amazon EC2 Auto Scaling doesn't execute scaling policies associated with an alarm. For valid values, see the `ScalingProcesses.member.N` parameter for the SuspendProcesses action in the *Amazon EC2 Auto Scaling API Reference*.

Default: Not specified

Type: List of Auto Scaling processes

Required: No

`WaitOnResourceSignals`

Specifies whether the Auto Scaling group waits on signals from new instances during an update. Use this property to ensure that instances have completed installing and configuring applications before the Auto Scaling group update proceeds. AWS CloudFormation suspends the update of an Auto Scaling group after new EC2 instances are launched into the group. AWS CloudFormation must receive a signal from each new instance within the specified `PauseTime` before continuing the update. To signal the Auto Scaling group, use the cfn-signal helper script or `SignalResource` API.

To have instances wait for an Elastic Load Balancing health check before they signal success, add a health-check verification by using the cfn-init helper script. For an example, see the `verify_instance_health` command in the Auto Scaling rolling updates sample template.

Default: `false`

Type: Boolean

Required: Conditional. If you specify the `MinSuccessfulInstancesPercent` property, you must also enable the `WaitOnResourceSignals` and `PauseTime` properties.

AutoScalingScheduledAction Policy

To specify how AWS CloudFormation handles updates for the `MinSize`, `MaxSize`, and `DesiredCapacity` properties when the `AWS::AutoScaling::AutoScalingGroup` resource has an associated scheduled action, use the `AutoScalingScheduledAction` policy.

With scheduled actions, the group size properties of an Auto Scaling group can change at any time. When you update a stack with an Auto Scaling group and scheduled action, AWS CloudFormation always sets the group size property values of your Auto Scaling group to the values that are defined in the `AWS::AutoScaling::AutoScalingGroup` resource of your template, even if a scheduled action is in effect.

If you do not want AWS CloudFormation to change any of the group size property values when you have a scheduled action in effect, use the `AutoScalingScheduledAction` update policy to prevent AWS CloudFormation from changing the `MinSize`, `MaxSize`, or `DesiredCapacity` properties unless you have modified these values in your template.

Syntax

JSON

```
"UpdatePolicy" : {
  "AutoScalingScheduledAction (p. 2284)" : {
    "IgnoreUnmodifiedGroupSizeProperties" : Boolean
  }
}
```

YAML

```
UpdatePolicy:
  AutoScalingScheduledAction (p. 2284):
    IgnoreUnmodifiedGroupSizeProperties: Boolean
```

Properties

`IgnoreUnmodifiedGroupSizeProperties`

Specifies whether AWS CloudFormation ignores differences in group size properties between your current Auto Scaling group and the Auto Scaling group described in the `AWS::AutoScaling::AutoScalingGroup` resource of your template during a stack update. If you modify any of the group size property values in your template, AWS CloudFormation uses the modified values and updates your Auto Scaling group.

Default: `false`

Type: Boolean

Required: No

CodeDeployLambdaAliasUpdate Policy

To perform an AWS CodeDeploy deployment when the version changes on an `AWS::Lambda::Alias` resource, use the `CodeDeployLambdaAliasUpdate` update policy.

Syntax

JSON

```
"UpdatePolicy" : {
  "CodeDeployLambdaAliasUpdate (p. 2285)" : {
    "AfterAllowTrafficHook" : String,
    "ApplicationName" : String,
    "BeforeAllowTrafficHook" : String,
```

```
    "DeploymentGroupName" : String
  }
}
```

YAML

```
UpdatePolicy:
  CodeDeployLambdaAliasUpdate (p. 2285):
    AfterAllowTrafficHook: String
    ApplicationName: String
    BeforeAllowTrafficHook: String
    DeploymentGroupName: String
```

Properties

`AfterAllowTrafficHook`

The name of the Lambda function to run after traffic routing completes.

Required: No

Type: String

`ApplicationName`

The name of the AWS CodeDeploy application.

Required: Yes

Type: String

`BeforeAllowTrafficHook`

The name of the Lambda function to run before traffic routing starts.

Required: No

Type: String

`DeploymentGroupName`

The name of the AWS CodeDeploy deployment group. This is where the traffic-shifting policy is set.

Required: Yes

Type: String

For an example that specifies the `UpdatePolicy` attribute for an `AWS::Lambda::Alias` resource, see Lambda Alias Update Policy (p. 2290).

UseOnlineResharding Policy

To modify a replication group's shards by adding or removing shards, rather than replacing the entire AWS::ElastiCache::ReplicationGroup (p. 1395) resource, use the `UseOnlineResharding` update policy.

If `UseOnlineResharding` is set to `true`, you can update the `NumNodeGroups` and `NodeGroupConfiguration` properties of the `AWS::ElastiCache::ReplicationGroup` resource, and CloudFormation will update those properties without interruption. When `UseOnlineResharding` is set to `false`, or not specified, updating the `NumNodeGroups` and `NodeGroupConfiguration` properties results in CloudFormation replacing the entire `AWS::ElastiCache::ReplicationGroup` resource.

The `UseOnlineResharding` update policy has no properties.

Things to consider when setting the `UseOnlineResharding` update policy to `true`:

- We strongly recommend you perform updates to the `NumNodeGroups` and `NodeGroupConfiguration` properties as the only updates in a given stack update operation.

  Updating the node group configuration of a replication group is a resource-intensive operation. If a stack update fails, CloudFormation does not roll back changes to the node group configuration of a replication group. However, CloudFormation will roll back any other properties that were changed as part of the failed update operation.
- Any node group updates require identifying all node groups

  If you specify the `NodeGroupConfiguration` property, you must also specify the NodeGroupId for each node group configuration in order for CloudFormation to update the number of nodes without interruption.

  When creating a replication group, if you do not specify an ID for each node group, ElastiCache automatically generates an ID for each node group. To update the replication group without interruption, use the ElastiCache console (https://console.aws.amazon.com/elasticache/) or DescribeReplicationGroups to retrieve the IDs for all node groups in the replication group. Then specify the ID for each node group in your stack template before attempting to add or remove shards.

  > **Note**
  > As a best practice, when you create a replication group in a stack template, include an ID for each node group you specify.

  In addition, updating the number of nodes without interruption requires that you have accurately specified the `PrimaryAvailabilityZone`, `ReplicaAvailabilityZones`, and `ReplicaCount` properties for each `NodeGroupConfiguration` as well. Again, you can use the ElastiCache console (https://console.aws.amazon.com/elasticache/) or DescribeReplicationGroups to retrieve the actual values for each node group and compare them to the values in your stack template. You can update the property values of the node groups as a separate stack update, or as part of the same stack update that changes the number of node groups.

  When you use an `UseOnlineResharding` update policy to update the number of node groups without interruption, ElastiCache evenly distributes the keyspaces between the specified number of slots. This cannot be updated later. Therefore, after updating the number of node groups in this way, you should remove the value specified for the `Slots` property of each `NodeGroupConfiguration` from the stack template, as it no longer reflects the actual values in each node group.
- Actual node group removal results may vary

  When you specify a `NumNodeGroups` value that is less than the current number of node groups, CloudFormation instructs ElastiCache to remove as many node groups as necessary to reach the specified number of nodes. However, ElastiCache may not always be able to remove the desired number of node groups. In the event ElastiCache cannot remove the desired number of node groups, CloudFormation generates a stack event alerting you to this. In cases where ElastiCache cannot remove *any* node groups, the CloudFormation resource update fails.

For more information on modifying replication groups, see ModifyReplicationGroupShardConfiguration.html in the *Amazon ElastiCache API Reference*.

Syntax

JSON

```
"UpdatePolicy" : {
```

```
  "UseOnlineResharding (p. 2286)" : Boolean
}
```

YAML

```
UpdatePolicy:
  UseOnlineResharding (p. 2286): Boolean
```

Examples

The following examples show how to add an update policy to an Auto Scaling group and how to maintain availability when updating metadata.

Add an UpdatePolicy to an Auto Scaling Group

The following example shows how to add an update policy. During an update, the Auto Scaling group updates instances in batches of two and keeps a minimum of one instance in service. Because the `WaitOnResourceSignals` flag is set, the Auto Scaling group waits for new instances that are added to the group. The new instances must signal the Auto Scaling group before it updates the next batch of instances.

JSON

```
"ASG" : {
   "Type" : "AWS::AutoScaling::AutoScalingGroup",
   "Properties" : {
      "AvailabilityZones" : [
         "us-east-1a",
         "us-east-1b"
      ],
      "DesiredCapacity" : "1",
      "LaunchConfigurationName" : {
         "Ref" : "LaunchConfig"
      },
      "MaxSize" : "4",
      "MinSize" : "1"
   },
   "UpdatePolicy" : {
      "AutoScalingScheduledAction" : {
         "IgnoreUnmodifiedGroupSizeProperties" : "true"
      },
      "AutoScalingRollingUpdate" : {
         "MinInstancesInService" : "1",
         "MaxBatchSize" : "2",
         "WaitOnResourceSignals" : "true",
         "PauseTime" : "PT10M"
      }
   }
 },
"ScheduledAction" : {
   "Type" : "AWS::AutoScaling::ScheduledAction",
   "Properties" : {
      "AutoScalingGroupName" : {
         "Ref" : "ASG"
      },
      "DesiredCapacity" : "2",
      "StartTime" : "2017-06-02T20 : 00 : 00Z"
   }
}
```

YAML

```
ASG:
  Type: 'AWS::AutoScaling::AutoScalingGroup'
  Properties:
    AvailabilityZones:
    - us-east-1a
    - us-east-1b
    DesiredCapacity: '1'
    LaunchConfigurationName:
      Ref: LaunchConfig
    MaxSize: '4'
    MinSize: '1'
  UpdatePolicy:
    AutoScalingScheduledAction:
      IgnoreUnmodifiedGroupSizeProperties: 'true'
    AutoScalingRollingUpdate:
      MinInstancesInService: '1'
      MaxBatchSize: '2'
      WaitOnResourceSignals: 'true'
      PauseTime: PT10M
ScheduledAction:
  Type: 'AWS::AutoScaling::ScheduledAction'
  Properties:
    AutoScalingGroupName:
      Ref: ASG
    DesiredCapacity: '2'
    StartTime: '2017-06-02T20 : 00 : 00Z'
```

AutoScalingReplacingUpdate Policy

The following example declares a policy that forces an associated Auto Scaling group to be replaced during an update. For the update to succeed, a percentage of instances (specified by the `MinSuccessfulPercentParameter` parameter) must signal success within the `Timeout` period.

JSON

```
"UpdatePolicy" : {
  "AutoScalingReplacingUpdate" : {
    "WillReplace" : "true"
  }
},
"CreationPolicy" : {
  "ResourceSignal" : {
    "Count" : { "Ref" : "ResourceSignalsOnCreate"},
    "Timeout" : "PT10M"
  },
  "AutoScalingCreationPolicy" : {
    "MinSuccessfulInstancesPercent" : { "Ref" : "MinSuccessfulPercentParameter" }
  }
}
```

YAML

```
UpdatePolicy:
  AutoScalingReplacingUpdate:
    WillReplace: 'true'
CreationPolicy:
  ResourceSignal:
    Count: !Ref 'ResourceSignalsOnCreate'
    Timeout: PT10M
```

```
  AutoScalingCreationPolicy:
    MinSuccessfulInstancesPercent: !Ref 'MinSuccessfulPercentParameter'
```

Maintain Availability When Updating the Metadata for the cfn-init Helper Script

When you install software applications on your instances, you might use the `AWS::CloudFormation::Init` metadata key and the `cfn-init` helper script to bootstrap the instances in your Auto Scaling group. AWS CloudFormation installs the packages, runs the commands, and performs other bootstrapping actions described in the metadata.

When you update only the metadata (for example, when updating a package to another version), you can use the `cfn-hup` helper daemon to detect and apply the updates. However, the `cfn-hup` daemon runs independently on each instance. If the daemon happens to runs at the same time on all instances, your application or service might be unavailable during the update. To guarantee availability, you can force a rolling update so that AWS CloudFormation updates your instances one batch at a time.

> **Important**
> Forcing a rolling update requires AWS CloudFormation to create a new instance and then delete the old one. Any information stored on the old instance is lost.

To force a rolling update, change the logical ID of the launch configuration resource, and then update the stack and any references pointing to the original logic ID (such as the associated Auto Scaling group). AWS CloudFormation triggers a rolling update on the Auto Scaling group, replacing all instances.

Original Template

```
"LaunchConfig": {
  "Type" : "AWS::AutoScaling::LaunchConfiguration",
  "Metadata" : {
    "Comment" : "Install a simple PHP application",
    "AWS::CloudFormation::Init" : {
    ...
    }
  }
}
```

Updated Logical ID

```
"LaunchConfigUpdateRubygemsPkg": {
  "Type" : "AWS::AutoScaling::LaunchConfiguration",
  "Metadata" : {
    "Comment" : "Install a simple PHP application",
    "AWS::CloudFormation::Init" : {
    ...
    }
  }
}
```

Lambda Alias Update Policy

The following example specifies the `UpdatePolicy` attribute for an `AWS::Lambda::Alias` resource. All the details for the deployment are defined by the application and deployment group that are passed into the policy.

JSON

```
"Alias": {
```

```
  "Type": "AWS::Lambda::Alias",
  "Properties": {
    "FunctionName": {
      "Ref": "LambdaFunction"
    },
    "FunctionVersion": {
      "Fn::GetAtt": [
        "FunctionVersionTwo",
        "Version"
      ]
    },
    "Name": "MyAlias"
  },
  "UpdatePolicy": {
    "CodeDeployLambdaAliasUpdate": {
      "ApplicationName": {
        "Ref": "CodeDeployApplication"
      },
      "DeploymentGroupName": {
        "Ref": "CodeDeployDeploymentGroup"
      },
      "BeforeAllowTrafficHook": {
        "Ref": "PreHookLambdaFunction"
      },
      "AfterAllowTrafficHook": {
        "Ref": "PreHookLambdaFunction"
      }
    }
  }
}
```

YAML

```
Alias:
  Type: 'AWS::Lambda::Alias'
  Properties:
    FunctionName: !Ref LambdaFunction
    FunctionVersion: !GetAtt FunctionVersionTwo.Version
    Name: MyAlias
  UpdatePolicy:
    CodeDeployLambdaAliasUpdate:
      ApplicationName: !Ref CodeDeployApplication
      DeploymentGroupName: !Ref CodeDeployDeploymentGroup
      BeforeAllowTrafficHook: !Ref PreHookLambdaFunction
      AfterAllowTrafficHook: !Ref PreHookLambdaFunction
```

Intrinsic Function Reference

AWS CloudFormation provides several built-in functions that help you manage your stacks. Use intrinsic functions in your templates to assign values to properties that are not available until runtime.

> **Note**
> You can use intrinsic functions only in specific parts of a template. Currently, you can use intrinsic functions in resource properties, outputs, metadata attributes, and update policy attributes. You can also use intrinsic functions to conditionally create stack resources.

Topics

- Fn::Base64 (p. 2292)
- Fn::Cidr (p. 2293)

- Condition Functions (p. 2295)
- Fn::FindInMap (p. 2311)
- Fn::GetAtt (p. 2313)
- Fn::GetAZs (p. 2326)
- Fn::ImportValue (p. 2328)
- Fn::Join (p. 2331)
- Fn::Select (p. 2332)
- Fn::Split (p. 2335)
- Fn::Sub (p. 2337)
- Fn::Transform (p. 2340)
- Ref (p. 2341)

Fn::Base64

The intrinsic function `Fn::Base64` returns the Base64 representation of the input string. This function is typically used to pass encoded data to Amazon EC2 instances by way of the `UserData` property.

Declaration

JSON

```
{ "Fn::Base64" : valueToEncode }
```

YAML

Syntax for the full function name:

```
Fn::Base64: valueToEncode
```

Syntax for the short form:

```
!Base64 valueToEncode
```

Note
If you use the short form and immediately include another function in the `valueToEncode` parameter, use the full function name for at least one of the functions. For example, the following syntax is invalid:

```
!Base64 !Sub string
!Base64 !Ref logical_ID
```

Instead, use the full function name for at least one of the functions, as shown in the following examples:

```
!Base64
  "Fn::Sub": string

Fn::Base64:
```

```
!Sub string
```

Parameters

valueToEncode

The string value you want to convert to Base64.

Return Value:

The original string, in Base64 representation.

Example

JSON

```
{ "Fn::Base64" : "AWS CloudFormation" }
```

YAML

```
Fn::Base64: AWS CloudFormation
```

Supported Functions

You can use any function that returns a string inside the `Fn::Base64` function.

See Also

- Intrinsic Function Reference (p. 2291)

Fn::Cidr

The intrinsic function `Fn::Cidr` returns an array of CIDR address blocks. The number of CIDR blocks returned is dependent on the `count` parameter.

Declaration

JSON

```
{ "Fn::Cidr" : [ipBlock, count, cidrBits]}
```

YAML

Syntax for the full function name:

```
Fn::Cidr:
  - ipBlock
  - count
```

```
  - cidrBits
```

Syntax for the short form:

```
!Cidr [ ipBlock, count, cidrBits ]
```

Parameters

ipBlock

The user-specified CIDR address block to be split into smaller CIDR blocks.

count

The number of CIDRs to generate. Valid range is between 1 and 256.

cidrBits

The number of subnet bits for the CIDR. For example, specifying a value "8" for this parameter will create a CIDR with a mask of "/24".

> **Note**
> Subnet bits is the inverse of subnet mask. To calculate the required host bits for a given subnet bits, subtract the subnet bits from 32 for IPv4 or 128 for IPv6.

Return Value

An array of CIDR address blocks.

Example

Basic Usage

This example create 6 CIDRs with a subnet mask "/27" inside from a CIDR with a mask of "/24".

JSON

```
{ "Fn::Cidr" : [ "192.168.0.0/24", "6", "5"] }
```

YAML

```
!Cidr [ "192.168.0.0/24", 6, 5 ]
```

Creating an IPv6 enabled VPC

This example template creates an IPv6 enabled subnet.

JSON

```
{
  "Resources" : {
    "ExampleVpc" : {
      "Type" : "AWS::EC2::VPC",
```

```
      "Properties" : {
        "CidrBlock" : "10.0.0.0/16"
      }
    },
    "IPv6CidrBlock" : {
      "Type" : "AWS::EC2::VPCCidrBlock",
      "Properties" : {
        "AmazonProvidedIpv6CidrBlock" : true,
        "VpcId" : { "Ref" : "ExampleVpc" }
      }
    },
    "ExampleSubnet" : {
      "Type" : "AWS::EC2::Subnet",
      "DependsOn" : "IPv6CidrBlock",
      "Properties" : {
        "AssignIpv6AddressOnCreation" : true,
        "CidrBlock" : { "Fn::Select" : [ 0, { "Fn::Cidr" : [{ "Fn::GetAtt" :
 [ "ExampleVpc", "CidrBlock" ]}, 1, 8 ]}]},
        "Ipv6CidrBlock" : { "Fn::Select" : [ 0, { "Fn::Cidr" : [{ "Fn::Select" : [ 0,
 { "Fn::GetAtt" : [ "ExampleVpc", "Ipv6CidrBlocks" ]}]}, 1, 64 ]}]},
        "VpcId" : { "Ref" : "ExampleVpc" }
      }
    }
  }
}
```

YAML

```
Resources:
    ExampleVpc:
        Type: AWS::EC2::VPC
        Properties:
            CidrBlock: "10.0.0.0/16"
     IPv6CidrBlock:
        Type: AWS::EC2::VPCCidrBlock
        Properties:
            AmazonProvidedIpv6CidrBlock: true
            VpcId: !Ref ExampleVpc
     ExampleSubnet:
        Type: AWS::EC2::Subnet
        DependsOn: IPv6CidrBlock
        Properties:
            AssignIpv6AddressOnCreation: true
            CidrBlock: !Select [ 0, !Cidr [ !GetAtt ExampleVpc.CidrBlock, 1, 8 ]]
            Ipv6CidrBlock: !Select [ 0, !Cidr [ !Select [ 0, !GetAtt
 ExampleVpc.Ipv6CidrBlocks], 1, 64 ]]
            VpcId: !Ref ExampleVpc
```

Supported Functions

You can use the following functions in a `Fn::Cidr` function:

- `Fn::Select` (p. 2332)
- `Ref` (p. 2341)

Condition Functions

You can use intrinsic functions, such as `Fn::If`, `Fn::Equals`, and `Fn::Not`, to conditionally create stack resources. These conditions are evaluated based on input parameters that you declare when you

create or update a stack. After you define all your conditions, you can associate them with resources or resource properties in the Resources and Outputs sections of a template.

You define all conditions in the Conditions section of a template except for `Fn::If` conditions. You can use the `Fn::If` condition in the metadata attribute, update policy attribute, and property values in the Resources section and Outputs sections of a template.

You might use conditions when you want to reuse a template that can create resources in different contexts, such as a test environment versus a production environment. In your template, you can add an `EnvironmentType` input parameter, which accepts either **`prod`** or **`test`** as inputs. For the production environment, you might include Amazon EC2 instances with certain capabilities; however, for the test environment, you want to use less capabilities to save costs. With conditions, you can define which resources are created and how they're configured for each environment type.

For more information about the Conditions section, see Conditions (p. 189).

> **Note**
> You can only reference other conditions and values from the Parameters and Mappings sections of a template. For example, you can reference a value from an input parameter, but you cannot reference the logical ID of a resource in a condition.

Topics

- Fn::And (p. 2297)
- Fn::Equals (p. 2298)
- Fn::If (p. 2299)
- Fn::Not (p. 2302)
- Fn::Or (p. 2303)
- Supported Functions (p. 2304)
- Sample Templates (p. 2304)

Associating a Condition

To conditionally create resources, resource properties, or outputs, you must associate a condition with them. Add the `Condition:` key and the logical ID of the condition as an attribute to associate a condition, as shown in the following snippet. AWS CloudFormation creates the `NewVolume` resource only when the `CreateProdResources` condition evaluates to true.

Example JSON

```
"NewVolume" : {
  "Type" : "AWS::EC2::Volume",
  "Condition" : "CreateProdResources",
  "Properties" : {
     "Size" : "100",
     "AvailabilityZone" : { "Fn::GetAtt" : [ "EC2Instance", "AvailabilityZone" ]}
}
```

Example YAML

```
NewVolume:
  Type: "AWS::EC2::Volume"
  Condition: CreateProdResources
  Properties:
    Size: 100
```

```
    AvailabilityZone: !GetAtt EC2Instance.AvailabilityZone
```

For the `Fn::If` function, you only need to specify the condition name. The following snippet shows how to use `Fn::If` to conditionally specify a resource property. If the `CreateLargeSize` condition is true, AWS CloudFormation sets the volume size to `100`. If the condition is false, AWS CloudFormation sets the volume size to `10`.

Example JSON

```
"NewVolume" : {
  "Type" : "AWS::EC2::Volume",
  "Properties" : {
    "Size" : {
      "Fn::If" : [
        "CreateLargeSize",
        "100",
        "10"
      ]},
    "AvailabilityZone" : { "Fn::GetAtt" : [ "Ec2Instance", "AvailabilityZone" ]}
  },
  "DeletionPolicy" : "Snapshot"
}
```

Example YAML

```
NewVolume:
  Type: "AWS::EC2::Volume"
  Properties:
    Size:
      !If [CreateLargeSize, 100, 10]
    AvailabilityZone: !GetAtt: Ec2Instance.AvailabilityZone
  DeletionPolicy: Snapshot
```

You can also use conditions inside other conditions. The following snippet is from the `Conditions` section of a template. The `MyAndCondition` condition includes the `SomeOtherCondition` condition:

Example JSON

```
"MyAndCondition": {
   "Fn::And": [
      {"Fn::Equals": ["sg-mysggroup", {"Ref": "ASecurityGroup"}]},
      {"Condition": "SomeOtherCondition"}
   ]
}
```

Example YAML

```
MyAndCondition: !And
  - !Equals ["sg-mysggroup", !Ref "ASecurityGroup"]
  - !Condition SomeOtherCondition
```

Fn::And

Returns `true` if all the specified conditions evaluate to true, or returns `false` if any one of the conditions evaluates to false. `Fn::And` acts as an AND operator. The minimum number of conditions that you can include is 2, and the maximum is 10.

Declaration

JSON

```
"Fn::And": [{condition}, {...}]
```

YAML

Syntax for the full function name:

```
Fn::And: [condition]
```

Syntax for the short form:

```
!And [condition]
```

Parameters

`condition`

A condition that evaluates to `true` or `false`.

Example

The following `MyAndCondition` evaluates to true if the referenced security group name is equal to `sg-mysggroup` and if `SomeOtherCondition` evaluates to true:

JSON

```
"MyAndCondition": {
   "Fn::And": [
      {"Fn::Equals": ["sg-mysggroup", {"Ref": "ASecurityGroup"}]},
      {"Condition": "SomeOtherCondition"}
   ]
}
```

YAML

```
MyAndCondition: !And
  - !Equals ["sg-mysggroup", !Ref ASecurityGroup]
  - !Condition SomeOtherCondition
```

Fn::Equals

Compares if two values are equal. Returns `true` if the two values are equal or `false` if they aren't.

Declaration

JSON

```
"Fn::Equals" : ["value_1", "value_2"]
```

YAML

Syntax for the full function name:

```
Fn::Equals: [value_1, value_2]
```

Syntax for the short form:

```
!Equals [value_1, value_2]
```

Parameters

`value`

A value of any type that you want to compare.

Example

The following `UseProdCondition` condition evaluates to true if the value for the `EnvironmentType` parameter is equal to `prod`:

JSON

```
"UseProdCondition" : {
   "Fn::Equals": [
      {"Ref": "EnvironmentType"},
      "prod"
   ]
}
```

YAML

```
UseProdCondition:
  !Equals [!Ref EnvironmentType, prod]
```

Fn::If

Returns one value if the specified condition evaluates to `true` and another value if the specified condition evaluates to `false`. Currently, AWS CloudFormation supports the `Fn::If` intrinsic function in the metadata attribute, update policy attribute, and property values in the Resources section and Outputs sections of a template. You can use the `AWS::NoValue` pseudo parameter as a return value to remove the corresponding property.

Declaration

JSON

```
"Fn::If": [condition_name, value_if_true, value_if_false]
```

YAML

Syntax for the full function name:

```
Fn::If: [condition_name, value_if_true, value_if_false]
```

Syntax for the short form:

```
!If [condition_name, value_if_true, value_if_false]
```

Parameters

`condition_name`

A reference to a condition in the Conditions section. Use the condition's name to reference it.

`value_if_true`

A value to be returned if the specified condition evaluates to `true`.

`value_if_false`

A value to be returned if the specified condition evaluates to `false`.

Examples

To view additional samples, see Sample Templates (p. 2304).

Example 1

The following snippet uses an `Fn::If` function in the `SecurityGroups` property for an Amazon EC2 resource. If the `CreateNewSecurityGroup` condition evaluates to true, AWS CloudFormation uses the referenced value of `NewSecurityGroup` to specify the `SecurityGroups` property; otherwise, AWS CloudFormation uses the referenced value of `ExistingSecurityGroup`.

JSON

```
"SecurityGroups" : [{
  "Fn::If" : [
    "CreateNewSecurityGroup",
    {"Ref" : "NewSecurityGroup"},
    {"Ref" : "ExistingSecurityGroup"}
  ]
}]
```

YAML

```
SecurityGroups:
  - !If [CreateNewSecurityGroup, !Ref NewSecurityGroup, !Ref ExistingSecurityGroup]
```

Example 2

In the Output section of a template, you can use the `Fn::If` function to conditionally output information. In the following snippet, if the `CreateNewSecurityGroup` condition evaluates to true, AWS CloudFormation outputs the security group ID of the `NewSecurityGroup` resource. If the condition is false, AWS CloudFormation outputs the security group ID of the `ExistingSecurityGroup` resource.

JSON

```
"Outputs" : {
```

```
  "SecurityGroupId" : {
    "Description" : "Group ID of the security group used.",
    "Value" : {
      "Fn::If" : [
        "CreateNewSecurityGroup",
        {"Ref" : "NewSecurityGroup"},
        {"Ref" : "ExistingSecurityGroup"}
      ]
    }
  }
}
```

YAML

```
Outputs:
  SecurityGroupId:
    Description: Group ID of the security group used.
    Value: !If [CreateNewSecurityGroup, !Ref NewSecurityGroup, !Ref ExistingSecurityGroup]
```

Example 3

The following snippet uses the `AWS::NoValue` pseudo parameter in an `Fn::If` function. The condition uses a snapshot for an Amazon RDS DB instance only if a snapshot ID is provided. If the `UseDBSnapshot` condition evaluates to true, AWS CloudFormation uses the `DBSnapshotName` parameter value for the `DBSnapshotIdentifier` property. If the condition evaluates to false, AWS CloudFormation removes the `DBSnapshotIdentifier` property.

JSON

```
"MyDB" : {
  "Type" : "AWS::RDS::DBInstance",
  "Properties" : {
    "AllocatedStorage" : "5",
    "DBInstanceClass" : "db.m1.small",
    "Engine" : "MySQL",
    "EngineVersion" : "5.5",
    "MasterUsername" : { "Ref" : "DBUser" },
    "MasterUserPassword" : { "Ref" : "DBPassword" },
    "DBParameterGroupName" : { "Ref" : "MyRDSParamGroup" },
    "DBSnapshotIdentifier" : {
      "Fn::If" : [
        "UseDBSnapshot",
        {"Ref" : "DBSnapshotName"},
        {"Ref" : "AWS::NoValue"}
      ]
    }
  }
}
```

YAML

```
MyDB:
  Type: "AWS::RDS::DBInstance"
  Properties:
    AllocatedStorage: 5
    DBInstanceClass: db.m1.small
    Engine: MySQL
    EngineVersion: 5.5
    MasterUsername: !Ref DBUser
    MasterUserPassword: !Ref DBPassword
```

```
    DBParameterGroupName: !Ref MyRDSParamGroup
    DBSnapshotIdentifier:
      !If [UseDBSnapshot, !Ref DBSnapshotName, !Ref "AWS::NoValue"]
```

Example 4

The following snippet provides an auto scaling update policy only if the `RollingUpdates` condition evaluates to true. If the condition evaluates to false, AWS CloudFormation removes the `AutoScalingRollingUpdate` update policy.

JSON

```
"UpdatePolicy": {
  "AutoScalingRollingUpdate": {
    "Fn::If": [
      "RollingUpdates",
      {
        "MaxBatchSize": "2",
        "MinInstancesInService": "2",
        "PauseTime": "PT0M30S"
      },
      {
        "Ref" : "AWS::NoValue"
      }
    ]
  }
}
```

YAML

```
UpdatePolicy:
  AutoScalingRollingUpdate:
    !If
      - RollingUpdates
      -
        MaxBatchSize: 2
        MinInstancesInService: 2
        PauseTime: PT0M30S
      - !Ref "AWS::NoValue"
```

Fn::Not

Returns `true` for a condition that evaluates to `false` or returns `false` for a condition that evaluates to `true`. `Fn::Not` acts as a NOT operator.

Declaration

JSON

```
"Fn::Not": [{condition}]
```

YAML

Syntax for the full function name:

```
Fn::Not: [condition]
```

Syntax for the short form:

```
!Not [condition]
```

Parameters

`condition`

A condition such as `Fn::Equals` that evaluates to `true` or `false`.

Example

The following `EnvCondition` condition evaluates to true if the value for the `EnvironmentType` parameter is not equal to `prod`:

JSON

```
"MyNotCondition" : {
   "Fn::Not" : [{
      "Fn::Equals" : [
         {"Ref" : "EnvironmentType"},
         "prod"
      ]
   }]
}
```

YAML

```
MyNotCondition:
  !Not [!Equals [!Ref EnvironmentType, prod]]
```

Fn::Or

Returns `true` if any one of the specified conditions evaluate to true, or returns `false` if all of the conditions evaluates to false. `Fn::Or` acts as an OR operator. The minimum number of conditions that you can include is 2, and the maximum is 10.

Declaration

JSON

```
"Fn::Or": [{condition}, {...}]
```

YAML

Syntax for the full function name:

```
Fn::Or: [condition, ...]
```

Syntax for the short form:

```
!Or [condition, ...]
```

Parameters

`condition`

A condition that evaluates to `true` or `false`.

Example

The following `MyOrCondition` evaluates to true if the referenced security group name is equal to `sg-mysggroup` or if `SomeOtherCondition` evaluates to true:

JSON

```
"MyOrCondition" : {
   "Fn::Or" : [
      {"Fn::Equals" : ["sg-mysggroup", {"Ref" : "ASecurityGroup"}]},
      {"Condition" : "SomeOtherCondition"}
   ]
}
```

YAML

```
MyOrCondition:
  !Or [!Equals [sg-mysggroup, !Ref ASecurityGroup], Condition: SomeOtherCondition]
```

Supported Functions

You can use the following functions in the `Fn::If` condition:

- `Fn::Base64`
- `Fn::FindInMap`
- `Fn::GetAtt`
- `Fn::GetAZs`
- `Fn::If`
- `Fn::Join`
- `Fn::Select`
- `Fn::Sub`
- `Ref`

You can use the following functions in all other condition functions, such as `Fn::Equals` and `Fn::Or`:

- `Fn::FindInMap`
- `Ref`
- Other condition functions

Sample Templates

Conditionally create resources for a production, development, or test stack

In some cases, you might want to create stacks that are similar but with minor tweaks. For example, you might have a template that you use for production applications. You want to create the same production stack so that you can use it for development or testing. However, for development and testing, you might not require all the extra capacity that's included in a production-level stack. Instead, you can use

an environment type input parameter in order to conditionally create stack resources that are specific to production, development, or testing, as shown in the following sample:

Example JSON

```
{
  "AWSTemplateFormatVersion" : "2010-09-09",

  "Mappings" : {
    "RegionMap" : {
      "us-east-1"      : { "AMI" : "ami-0ff8a91507f77f867"},
      "us-west-1"      : { "AMI" : "ami-0bdb828fd58c52235"},
      "us-west-2"      : { "AMI" : "ami-a0cfeed8"},
      "eu-west-1"      : { "AMI" : "ami-047bb4163c506cd98"},
      "sa-east-1"      : { "AMI" : "ami-07b14488da8ea02a0"},
      "ap-southeast-1" : { "AMI" : "ami-08569b978cc4dfa10"},
      "ap-southeast-2" : { "AMI" : "ami-09b42976632b27e9b"},
      "ap-northeast-1" : { "AMI" : "ami-06cd52961ce9f0d85"}
    }
  },

  "Parameters" : {
    "EnvType" : {
      "Description" : "Environment type.",
      "Default" : "test",
      "Type" : "String",
      "AllowedValues" : ["prod", "dev", "test"],
      "ConstraintDescription" : "must specify prod, dev, or test."
    }
  },

  "Conditions" : {
    "CreateProdResources" : {"Fn::Equals" : [{"Ref" : "EnvType"}, "prod"]},
    "CreateDevResources" : {"Fn::Equals" : [{"Ref" : "EnvType"}, "dev"]}
  },

  "Resources" : {
    "EC2Instance" : {
      "Type" : "AWS::EC2::Instance",
      "Properties" : {
        "ImageId" : { "Fn::FindInMap" : [ "RegionMap", { "Ref" : "AWS::Region" }, "AMI" ]},
        "InstanceType" : { "Fn::If" : [
          "CreateProdResources",
          "c1.xlarge",
          {"Fn::If" : [
            "CreateDevResources",
            "m1.large",
            "m1.small"
          ]}
        ]}
      }
    },

    "MountPoint" : {
      "Type" : "AWS::EC2::VolumeAttachment",
      "Condition" : "CreateProdResources",
      "Properties" : {
        "InstanceId" : { "Ref" : "EC2Instance" },
        "VolumeId"  : { "Ref" : "NewVolume" },
        "Device" : "/dev/sdh"
      }
    },

    "NewVolume" : {
      "Type" : "AWS::EC2::Volume",
```

```
      "Condition" : "CreateProdResources",
      "Properties" : {
        "Size" : "100",
        "AvailabilityZone" : { "Fn::GetAtt" : [ "EC2Instance", "AvailabilityZone" ]}
      }
    }
  }
}
```

Example YAML

```
AWSTemplateFormatVersion: "2010-09-09"

Mappings:
  RegionMap:
    us-east-1:
      AMI: "ami-0ff8a91507f77f867"
    us-west-1:
      AMI: "ami-0bdb828fd58c52235"
    us-west-2:
      AMI: "ami-a0cfeed8"
    eu-west-1:
      AMI: "ami-047bb4163c506cd98"
    sa-east-1:
      AMI: "ami-07b14488da8ea02a0"
    ap-southeast-1:
      AMI: "ami-08569b978cc4dfa10"
    ap-southeast-2:
      AMI: "ami-09b42976632b27e9b"
    ap-northeast-1:
      AMI: "ami-06cd52961ce9f0d85"

Parameters:
  EnvType:
    Description: Environment type.
    Default: test
    Type: String
    AllowedValues: [prod, dev, test]
    ConstraintDescription: must specify prod, dev, or test.

Conditions:
  CreateProdResources: !Equals [!Ref EnvType, prod]
  CreateDevResources: !Equals [!Ref EnvType, "dev"]

Resources:
  EC2Instance:
    Type: "AWS::EC2::Instance"
    Properties:
      ImageId: !FindInMap [RegionMap, !Ref "AWS::Region", AMI]
      InstanceType: !If [CreateProdResources, c1.xlarge, !If [CreateDevResources, m1.large,
 m1.small]]
  MountPoint:
    Type: "AWS::EC2::VolumeAttachment"
    Condition: CreateProdResources
    Properties:
      InstanceId: !Ref EC2Instance
      VolumeId: !Ref NewVolume
      Device: /dev/sdh
  NewVolume:
    Type: "AWS::EC2::Volume"
    Condition: CreateProdResources
    Properties:
      Size: 100
      AvailabilityZone: !GetAtt EC2Instance.AvailabilityZone
```

You can specify `prod`, `dev`, or `test` for the `EnvType` parameter. For each environment type, the template specifies a different instance type. The instance types can range from a large, compute-optimized instance type to a small general purpose instance type. In order to conditionally specify the instance type, the template defines two conditions in the Conditions section of the template: `CreateProdResources`, which evaluates to true if the `EnvType` parameter value is equal to `prod` and `CreateDevResources`, which evaluates to true if the parameter value is equal to `dev`.

In the `InstanceType` property, the template nests two `Fn::If` intrinsic functions to determine which instance type to use. If the `CreateProdResources` condition is true, the instance type is `c1.xlarge`. If the condition is false, the `CreateDevResources` condition is evaluated. If the `CreateDevResources` condition is true, the instance type is `m1.large` or else the instance type is `m1.small`.

In addition to the instance type, the production environment creates and attaches an Amazon EC2 volume to the instance. The `MountPoint` and `NewVolume` resources are associated with the `CreateProdResources` condition so that the resources are created only if the condition evaluates to true.

Conditionally assign a resource property

In this example, you can create an Amazon RDS DB instance from a snapshot. If you specify the `DBSnapshotName` parameter, AWS CloudFormation uses the parameter value as the snapshot name when creating the DB instance. If you keep the default value (empty string), AWS CloudFormation removes the `DBSnapshotIdentifier` property and creates a DB instance from scratch.

Example JSON

```
{
  "AWSTemplateFormatVersion" : "2010-09-09",

  "Parameters": {
    "DBUser": {
      "NoEcho": "true",
      "Description" : "The database admin account username",
      "Type": "String",
      "MinLength": "1",
      "MaxLength": "16",
      "AllowedPattern" : "[a-zA-Z][a-zA-Z0-9]*",
      "ConstraintDescription" : "must begin with a letter and contain only alphanumeric
 characters."
    },
    "DBPassword": {
      "NoEcho": "true",
      "Description" : "The database admin account password",
      "Type": "String",
      "MinLength": "1",
      "MaxLength": "41",
      "AllowedPattern" : "[a-zA-Z0-9]*",
      "ConstraintDescription" : "must contain only alphanumeric characters."
    },
    "DBSnapshotName": {
      "Description": "The name of a DB snapshot (optional)",
      "Default": "",
      "Type": "String"
    }
  },

  "Conditions": {
    "UseDBSnapshot": {"Fn::Not": [{"Fn::Equals" : [{"Ref" : "DBSnapshotName"}, ""]}]}
  },

  "Resources" : {
    "MyDB" : {
```

```
      "Type" : "AWS::RDS::DBInstance",
      "Properties" : {
        "AllocatedStorage" : "5",
        "DBInstanceClass" : "db.m1.small",
        "Engine" : "MySQL",
        "EngineVersion" : "5.5",
        "MasterUsername" : { "Ref" : "DBUser" },
        "MasterUserPassword" : { "Ref" : "DBPassword" },
        "DBParameterGroupName" : { "Ref" : "MyRDSParamGroup" },
        "DBSnapshotIdentifier" : {
          "Fn::If" : [
            "UseDBSnapshot",
            {"Ref" : "DBSnapshotName"},
            {"Ref" : "AWS::NoValue"}
          ]
        }
      }
    },

    "MyRDSParamGroup" : {
      "Type": "AWS::RDS::DBParameterGroup",
      "Properties" : {
        "Family" : "MySQL5.5",
        "Description" : "CloudFormation Sample Database Parameter Group",
          "Parameters" : {
            "autocommit" : "1" ,
            "general_log" : "1",
            "old_passwords" : "0"
        }
      }
    }
  }
}
```

Example YAML

```
AWSTemplateFormatVersion: "2010-09-09"
Parameters:
  DBUser:
    NoEcho: true
    Description: The database admin account username
    Type: String
    MinLength: 1
    MaxLength: 16
    AllowedPattern: "[a-zA-Z][a-zA-Z0-9]*"
    ConstraintDescription: must begin with a letter and contain only alphanumeric
 characters.
  DBPassword:
    NoEcho: true
    Description: The database admin account password
    Type: String
    MinLength: 1
    MaxLength: 41
    AllowedPattern: "[a-zA-Z0-9]*"
    ConstraintDescription: must contain only alphanumeric characters.
  DBSnapshotName:
    Description: The name of a DB snapshot (optional)
    Default: ""
    Type: String
Conditions:
  UseDBSnapshot: !Not [!Equals [!Ref DBSnapshotName, ""]]
Resources:
  MyDB:
    Type: "AWS::RDS::DBInstance"
```

```
    Properties:
      AllocatedStorage: 5
      DBInstanceClass: db.m1.small
      Engine: MySQL
      EngineVersion: 5.5
      MasterUsername: !Ref DBUser
      MasterUserPassword: !Ref DBPassword
      DBParameterGroupName: !Ref MyRDSParamGroup
      DBSnapshotIdentifier: !If [UseDBSnapshot, !Ref DBSnapshotName, !Ref "AWS::NoValue"]
  MyRDSParamGroup:
    Type: "AWS::RDS::DBParameterGroup"
    Properties:
      Family: MySQL5.5
      Description: CloudFormation Sample Database Parameter Group
      Parameters:
        autocommit: 1
        general_log: 1
        old_passwords: 0
```

The `UseDBSnapshot` condition evaluates to true only if the `DBSnapshotName` is not an empty string. If the `UseDBSnapshot` condition evaluates to true, AWS CloudFormation uses the `DBSnapshotName` parameter value for the `DBSnapshotIdentifier` property. If the condition evaluates to false, AWS CloudFormation removes the `DBSnapshotIdentifier` property. The `AWS::NoValue` pseudo parameter removes the corresponding resource property when it is used as a return value.

Conditionally use an existing resource

In this example, you can use an Amazon EC2 security group that has already been created or you can create a new security group, which is specified in the template. For the `ExistingSecurityGroup` parameter, you can specify the `default` security group name or `NONE`. If you specify `default`, AWS CloudFormation uses a security group that has already been created and is named `default`. If you specify `NONE`, AWS CloudFormation creates the security group that's defined in the template.

Example JSON

```
{
  "Parameters" : {
    "ExistingSecurityGroup" : {
      "Description" : "An existing security group ID (optional).",
      "Default" : "NONE",
      "Type" : "String",
      "AllowedValues" : ["default", "NONE"]
    }
  },

  "Conditions" : {
    "CreateNewSecurityGroup" : {"Fn::Equals" : [{"Ref" : "ExistingSecurityGroup"},
 "NONE"] }
  },

  "Resources" : {
    "MyInstance" : {
      "Type" : "AWS::EC2::Instance",
        "Properties" : {
          "ImageId" : "ami-0ff8a91507f77f867",
          "SecurityGroups" : [{
            "Fn::If" : [
              "CreateNewSecurityGroup",
              {"Ref" : "NewSecurityGroup"},
              {"Ref" : "ExistingSecurityGroup"}
            ]
          }]
        }
```

```
    },

    "NewSecurityGroup" : {
      "Type" : "AWS::EC2::SecurityGroup",
      "Condition" : "CreateNewSecurityGroup",
      "Properties" : {
        "GroupDescription" : "Enable HTTP access via port 80",
        "SecurityGroupIngress" : [ {
          "IpProtocol" : "tcp",
          "FromPort" : "80",
          "ToPort" : "80",
          "CidrIp" : "0.0.0.0/0"
        } ]
      }
    }
  },

  "Outputs" : {
    "SecurityGroupId" : {
      "Description" : "Group ID of the security group used.",
      "Value" : {
        "Fn::If" : [
          "CreateNewSecurityGroup",
          {"Ref" : "NewSecurityGroup"},
          {"Ref" : "ExistingSecurityGroup"}
        ]
      }
    }
  }
}
```

Example YAML

```
Parameters:
  ExistingSecurityGroup:
    Description: An existing security group ID (optional).
    Default: NONE
    Type: String
    AllowedValues:
      - default
      - NONE
Conditions:
  CreateNewSecurityGroup: !Equals [!Ref ExistingSecurityGroup, NONE]
Resources:
  MyInstance:
    Type: "AWS::EC2::Instance"
    Properties:
      ImageId: "ami-0ff8a91507f77f867"
      SecurityGroups: !If [CreateNewSecurityGroup, !Ref NewSecurityGroup, !Ref
 ExistingSecurityGroup]
  NewSecurityGroup:
    Type: "AWS::EC2::SecurityGroup"
    Condition: CreateNewSecurityGroup
    Properties:
      GroupDescription: Enable HTTP access via port 80
      SecurityGroupIngress:
        -
          IpProtocol: tcp
          FromPort: 80
          ToPort: 80
          CidrIp: 0.0.0.0/0
Outputs:
  SecurityGroupId:
```

```
    Description: Group ID of the security group used.
    Value: !If [CreateNewSecurityGroup, !Ref NewSecurityGroup, !Ref ExistingSecurityGroup]
```

To determine whether to create the `NewSecurityGroup` resource, the resource is associated with the `CreateNewSecurityGroup` condition. The resource is created only when the condition is true (when the `ExistingSecurityGroup` parameter is equal to `NONE`).

In the `SecurityGroups` property, the template uses the `Fn::If` intrinsic function to determine which security group to use. If the `CreateNewSecurityGroup` condition evaluates to true, the security group property references the `NewSecurityGroup` resource. If the `CreateNewSecurityGroup` condition evaluates to false, the security group property references the `ExistingSecurityGroup` parameter (the `default` security group).

Lastly, the template conditionally outputs the security group ID. If the `CreateNewSecurityGroup` condition evaluates to true, AWS CloudFormation outputs the security group ID of the `NewSecurityGroup` resource. If the condition is false, AWS CloudFormation outputs the security group ID of the `ExistingSecurityGroup` resource.

Fn::FindInMap

The intrinsic function `Fn::FindInMap` returns the value corresponding to keys in a two-level map that is declared in the `Mappings` section.

Declaration

JSON

```
{ "Fn::FindInMap" : [ "MapName", "TopLevelKey", "SecondLevelKey"] }
```

YAML

Syntax for the full function name:

```
Fn::FindInMap: [ MapName, TopLevelKey, SecondLevelKey ]
```

Syntax for the short form:

```
!FindInMap [ MapName, TopLevelKey, SecondLevelKey ]
```

> **Note**
> You can't nest two instances of two functions in short form.

Parameters

MapName

The logical name of a mapping declared in the Mappings section that contains the keys and values.

TopLevelKey

The top-level key name. Its value is a list of key-value pairs.

SecondLevelKey

The second-level key name, which is set to one of the keys from the list assigned to `TopLevelKey`.

Return Value:

The value that is assigned to `SecondLevelKey`.

Example

The following example shows how to use `Fn::FindInMap` for a template with a `Mappings` section that contains a single map, `RegionMap`, that associates AMIs with AWS regions.

- The map has 5 top-level keys that correspond to various AWS regions.
- Each top-level key is assigned a list with two second level keys, `"HVM64"` and `"HVMG2"`, that correspond to the AMI's architecture.
- Each of the second-level keys is assigned an appropriate AMI name.

The example template contains an `AWS::EC2::Instance` resource whose `ImageId` property is set by the `FindInMap` function.

`MapName` is set to the map of interest, `"RegionMap"` in this example. `TopLevelKey` is set to the region where the stack is created, which is determined by using the `"AWS::Region"` pseudo parameter. `SecondLevelKey` is set to the desired architecture, `"HVM64"` for this example.

`FindInMap` returns the AMI assigned to `FindInMap`. For a HVM64 instance in us-east-1, `FindInMap` would return `"ami-0ff8a91507f77f867"`.

JSON

```
{
  ...
  "Mappings" : {
    "RegionMap" : {
      "us-east-1" : {
        "HVM64" : "ami-0ff8a91507f77f867", "HVMG2" : "ami-0a584ac55a7631c0c"
      },
      "us-west-1" : {
        "HVM64" : "ami-0bdb828fd58c52235", "HVMG2" : "ami-066ee5fd4a9ef77f1"
      },
      "eu-west-1" : {
        "HVM64" : "ami-047bb4163c506cd98", "HVMG2" : "ami-0a7c483d527806435"
      },
      "ap-southeast-1" : {
        "HVM64" : "ami-08569b978cc4dfa10", "HVMG2" : "ami-0be9df32ae9f92309"
      },
      "ap-northeast-1" : {
        "HVM64" : "ami-06cd52961ce9f0d85", "HVMG2" : "ami-053cdd503598e4a9d"
      }
    }
  },

  "Resources" : {
    "myEC2Instance" : {
      "Type" : "AWS::EC2::Instance",
      "Properties" : {
        "ImageId" : {
          "Fn::FindInMap" : [
            "RegionMap",
            {
              "Ref" : "AWS::Region"
            },
            "HVM64"
          ]
        },
```

```
        "InstanceType" : "m1.small"
      }
    }
  }
}
```

YAML

```
Mappings:
  RegionMap:
    us-east-1:
      HVM64: "ami-0ff8a91507f77f867"

      HVM64: "ami-08569b978cc4dfa10"
      HVMG2: "ami-0be9df32ae9f92309"
    ap-northeast-1:
      HVM64: "ami-06cd52961ce9f0d85"
      HVMG2: "ami-053cdd503598e4a9d"
Resources:
  myEC2Instance:
    Type: "AWS::EC2::Instance"
    Properties:
      ImageId: !FindInMap
        - RegionMap
        - !Ref 'AWS::Region'
        - HVM64
      InstanceType: m1.small
```

Supported Functions

You can use the following functions in a `Fn::FindInMap` function:

- `Fn::FindInMap`
- `Ref`

`Fn::GetAtt`

The `Fn::GetAtt` intrinsic function returns the value of an attribute from a resource in the template.

Declaration

JSON

```
{ "Fn::GetAtt" : [ "logicalNameOfResource", "attributeName" ] }
```

YAML

Syntax for the full function name:

```
Fn::GetAtt: [ logicalNameOfResource, attributeName ]
```

Syntax for the short form:

```
!GetAtt logicalNameOfResource.attributeName
```

Parameters

`logicalNameOfResource`

The logical name (also called *logical ID*) of the resource that contains the attribute that you want.

`attributeName`

The name of the resource-specific attribute whose value you want. See the resource's reference page for details about the attributes available for that resource type.

Return Value

The attribute value.

Examples

Return a String

This example snippet returns a string containing the DNS name of the load balancer with the logical name `myELB`.

JSON

```
"Fn::GetAtt" : [ "myELB" , "DNSName" ]
```

YAML

```
!GetAtt myELB.DNSName
```

Return Multiple Strings

The following example template returns the `SourceSecurityGroup.OwnerAlias` and `SourceSecurityGroup.GroupName` of the load balancer with the logical name `myELB`.

JSON

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "myELB": {
            "Type": "AWS::ElasticLoadBalancing::LoadBalancer",
            "Properties": {
                "AvailabilityZones": [
                    "eu-west-1a"
                ],
                "Listeners": [
                    {
                        "LoadBalancerPort": "80",
                        "InstancePort": "80",
                        "Protocol": "HTTP"
                    }
```

```
                ]
            }
        },
        "myELBIngressGroup": {
            "Type": "AWS::EC2::SecurityGroup",
            "Properties": {
                "GroupDescription": "ELB ingress group",
                "SecurityGroupIngress": [
                    {
                        "IpProtocol": "tcp",
                        "FromPort": "80",
                        "ToPort": "80",
                        "SourceSecurityGroupOwnerId": {
                            "Fn::GetAtt": [
                                "myELB",
                                "SourceSecurityGroup",
                                "OwnerAlias"
                            ]
                        },
                        "SourceSecurityGroupName": {
                            "Fn::GetAtt": [
                                "myELB",
                                "SourceSecurityGroup",
                                "GroupName"
                            ]
                        }
                    }
                ]
            }
        }
    }
}
```

YAML

```
AWSTemplateFormatVersion: 2010-09-09
Resources:
  myELB:
    Type: AWS::ElasticLoadBalancing::LoadBalancer
    Properties:
      AvailabilityZones:
        - eu-west-1a
      Listeners:
        - LoadBalancerPort: '80'
          InstancePort: '80'
          Protocol: HTTP
  myELBIngressGroup:
    Type: AWS::EC2::SecurityGroup
    Properties:

      SecurityGroupIngress:
        - IpProtocol: tcp
          FromPort: '80'
          ToPort: '80'
          SourceSecurityGroupOwnerId: !GetAtt myELB.SourceSecurityGroup.OwnerAlias
          SourceSecurityGroupName: !GetAtt myELB.SourceSecurityGroup.GroupName
```

Supported Functions

For the `Fn::GetAtt` logical resource name, you cannot use functions. You must specify a string that is a resource's logical ID.

For the `Fn::GetAtt` attribute name, you can use the `Ref` function.

Attributes

You can retrieve the following attributes using `Fn::GetAtt`.

Resource TypeName	Attribute	Description
AWS::AmazonMQ::Broker (p. 520)	`Arn`	The Amazon Resource Name (ARN) of the Amazon MQ broker. Example: `arn:aws:mq:us-east-2:123456789012:broker:MyBroker:b-1234a5b6-78cd-901`
AWS::AmazonMQ::Broker (p. 520)	`ConfigurationId`	The unique ID that Amazon MQ generates for the configuration. Example: `c-1234a5b6-78cd-901e-2fgh-3i45j6k178l9`
AWS::AmazonMQ::Broker (p. 520)	`ConfigurationRevision`	The revision number of the Amazon MQ configuration. Example: `1`
AWS::AmazonMQ::Configuration (p. 530)	`Arn`	The Amazon Resource Name (ARN) of the Amazon MQ configuration. Example: `arn:aws:mq:us-east-2:123456789012:configuration:MyConfigurationDevelo`
AWS::AmazonMQ::Configuration (p. 530)	`Revision`	The revision number of the Amazon MQ configuration. Example: `1`
AWS::ApiGateway::DomainName (p. 566)	`DistributionDomainName`	The Amazon CloudFront distribution domain name that is mapped to the custom domain name. Example: `d111111abcdef8.cloudfront.net`
AWS::ApiGateway::RestApi (p. 588)	`RootResourceId`	The root resource ID for a `RestApi` resource. Example: `a0bc123d4e`
AWS::AppStream::ImageBuilder (p. 660)	`StreamingURL`	The URL to start an Amazon AppStream 2.0 image builder streaming session
AWS::Cloud9::EnvironmentEC2 (p. 791)	`Arn`	The Amazon Resource Name (ARN) of the AWS Cloud9 development environment. Example: `arn:aws:cloud9:us-east-2:123456789012:environment:2bc3642873c342e485f7e0c`
AWS::Cloud9::EnvironmentEC2 (p. 791)	`Name`	The name of the AWS Cloud9 development environment. Example: `my-demo-environment`
AWS::CloudFormation::WaitCondition (p. 827)	`Data`	A JSON-format string containing the `UniqueId` and `Data` values from the wait condition signal(s) for the specified wait condition. For more information about wait condition signals, see Wait Condition Signal JSON Format (p. 283). Example of a wait condition with two signals: `{"Signal1":"Step 1 complete.","Signal2":"Step 2 complete."}`

Resource TypeName	Attribute	Description
AWS::CloudFormation::Stack (p. 827)	`Outputs.`*`NestedStackOutputName`	The output value from the nested stack that you specified, where *`NestedStackOutputName`* is the name of the output value.
AWS::CloudFront::Distribution (p. 871)	`DomainName`	Example: `d2fadu0nynjpfn.cloudfront.net`
AWS::CloudTrail::Trail (p. 865)	`Arn`	Example: `arn:aws:cloudtrail:us-east-2:123456789012:trail/myCloudTrail`
AWS::CloudTrail::Trail (p. 865)	`SnsTopicArn`	The Amazon Resource Name (ARN) of the Amazon SNS topic that is associated with the CloudTrail trail. Example: `arn:aws:sns:us-east-2:123456789012:mySNSTopic`
AWS::CloudWatch::Alarm (p. 874)	`Arn`	Example: `arn:aws:cloudwatch:us-east-2:123456789012:alarm:myCloudWatchAlarm-CPUAlarm-UXMMZK36R55Z`
AWS::CodeBuild::Project (p. 911)	`Arn`	Example: `arn:aws:codebuild:us-west-2:123456789012:project/myProjectName`
AWS::CodeCommit::Repository (p. 931)	`Arn`	Example: `arn:aws:codecommit:us-east-2:123456789012:MyDemoRepo`
AWS::CodeCommit::Repository (p. 931)	`CloneUrlHttp`	Example: `https://codecommit.us-east-2.amazonaws.com/v1/repos/MyDemoRepo`
AWS::CodeCommit::Repository (p. 931)	`CloneUrlSsh`	Example: `ssh://git-codecommit.us-east-2.amazonaws.com/v1/repos//v1/repos/MyDemoRepo`
AWS::CodeCommit::Repository (p. 931)	`Name`	Example: `MyDemoRepo`
AWS::CodePipeline::Pipeline (p. 979)	`Version`	The pipeline version. Example: `1`
AWS::CodePipeline::Webhook (p. 991)	`Url`	Example: `https://eu-central-1.webhooks.aws/trigger123456`
AWS::Config::ConfigRule (p. 1037)	`Arn`	Example: `arn:aws:config:us-east-2:123456789012:config-rule/config-rule-a1bzhi`
AWS::Config::ConfigRule (p. 1037)	`ConfigRuleId`	Example: `config-rule-a1bzhi`
AWS::Config::ConfigRule (p. 1037)	`Compliance.Type`	Example: `COMPLIANT`
AWS::DAX::Cluster (p. 1070)	`Arn`	Example: `arn:aws:dax:us-east-1:111122223333:cache/MyDAXCluster`
AWS::DAX::Cluster (p. 1070)	`ClusterDiscoveryEndpoint`	Example: `mydaxcluster.0h3d6x.clustercfg.dax.use1.cache.amazonaws`
AWS::DirectoryService::MicrosoftAD (p. 1083) and AWS::DirectoryService::SimpleAD (p. 1087)	`Alias`	The alias for a directory. Examples: `d-12373a053a` or `alias4-mydirectory-12345abcgmzsk` (if you have the `CreateAlias` property set to true)

Resource TypeName	Attribute	Description
AWS::DirectoryService::MicrosoftAD (p. 1083) and AWS::DirectoryService::SimpleAD (p. 1087)	`DnsIpAddresses`	The IP addresses of the DNS servers for the directory. Example: `[ "192.0.2.1", "192.0.2.2" ]`
AWS::DynamoDB::Table (p. 1115)	`Arn`	Example: `arn:aws:dynamodb:us-east-2:123456789012:table/myDynamoDBTable`
AWS::DynamoDB::Table (p. 1115)	`StreamArn`	The Amazon Resource Name (ARN) of the DynamoDB table stream. To use this attribute, you must specify the DynamoDB table `StreamSpecification` property. Example: `arn:aws:dynamodb:us-east-2:123456789012:table/testddbstack-myDynamoDBTable-012A1SL7SMP5Q/stream/2015-11-30T20:10:00.000`
AWS::EC2::EIP (p. 1144)	`AllocationId`	The ID that AWS assigns to represent the allocation of the address for use with Amazon VPC. It is returned only for VPC Elastic IP addresses. Example: `eipalloc-5723d13e`
AWS::EC2::Instance (p. 1155)	`AvailabilityZone`	The Availability Zone where the instance that you specified is launched. Example: `us-east-1b`
AWS::EC2::Instance (p. 1155)	`PrivateDnsName`	The private DNS name of the instance that you specified. Example: `ip-10-24-34-0.ec2.internal`
AWS::EC2::Instance (p. 1155)	`PublicDnsName`	The public DNS name of the instance that you specified. Example: `ec2-107-20-50-45.compute-1.amazonaws.com`
AWS::EC2::Instance (p. 1155)	`PrivateIp`	The private IP address of the instance that you specified. Example: `10.24.34.0`
AWS::EC2::Instance (p. 1155)	`PublicIp`	The public IP address of the instance that you specified. Example: `192.0.2.0`
AWS::EC2::NetworkInterface (p. 1298)	`PrimaryPrivateIpAddress`	The primary private IP address of the network interface that you specified. Example: `10.0.0.192`
AWS::EC2::NetworkInterface (p. 1298)	`SecondaryPrivateIpAddresses`	The secondary private IP addresses of the network interface that you specified. Example: `["10.0.0.161", "10.0.0.162", "10.0.0.163"]`
AWS::EC2::SecurityGroup (p. 1325)	`GroupId`	The group ID of the specified security group. Example: `sg-94b3a1f6`

Resource TypeName	Attribute	Description
AWS::EC2::Subnet (p. 1270)	`AvailabilityZone`	The Availability Zone of the subnet. Example: `us-east-1a`
AWS::EC2::Subnet (p. 1270)	`Ipv6CidrBlocks`	A list of IPv6 CIDR blocks that are associated with the subnet. Example: `[ 2001:db8:1234:1a00::/64 ]`
AWS::EC2::Subnet (p. 1270)	`NetworkAclAssociationId`	The ID of the network ACL that is associated with the subnet's VPC. Example: `acl-5fb85d36`
AWS::EC2::Subnet (p. 1270)	`VpcId`	The ID of the subnet's VPC. Example: `vpc-11ad4878`
AWS::EC2::SubnetNetworkAclAssociation (p. 1275)	`AssociationId`	The `NetworkAcl associationId` that is attached to a subnet.
AWS::EC2::VPC (p. 1285)	`CidrBlock`	The set of IP addresses for the VPC. Example: `10.0.0.0/16`
AWS::EC2::VPC (p. 1285)	`CidrBlockAssociations`	A list of IPv4 CIDR block association IDs for the VPC. Example: `[ vpc-cidr-assoc-0280ab6b ]`
AWS::EC2::VPC (p. 1285)	`DefaultNetworkAcl`	The default network ACL ID that is associated with the VPC, which AWS creates when you create a VPC. Example: `acl-814dafe3`
AWS::EC2::VPC (p. 1285)	`DefaultSecurityGroup`	The default security group ID that is associated with the VPC, which AWS creates when you create a VPC. Example: `sg-b178e0d3`
AWS::EC2::VPC (p. 1285)	`Ipv6CidrBlocks`	A list of IPv6 CIDR blocks that are associated with the VPC. Example: `[ 2001:db8:1234:1a00::/56 ]`
AWS::ECR::Repository (p. 1322)	`Arn`	Example: `arn:aws:ecr:us-east-2:123456789012:repository/test-repository`
AWS::ECS::Cluster (p. 1327)	`Arn`	Example: `arn:aws:ecs:us-east-2:123456789012:cluster/MyECSCluster`
AWS::ECS::Service (p. 1330)	`Name`	The name of an Amazon Elastic Container Service service. Example: `sample-webapp`
AWS::EKS::Cluster (p. 1332)	`Arn`	The ARN of the cluster. Example: `arn:aws:eks:us-east-2:123456789012:cluster/MyECSCluster`

Resource TypeName	Attribute	Description
AWS::EKS::Cluster (p. 1382)	`CertificateAuthorityData`	The `certificate-authority-data` for your cluster.
AWS::EKS::Cluster (p. 1382)	`Endpoint`	The endpoint for your Kubernetes API server. Example: `https://EXAMPLEFBBB3BA591B746AFC5AB30262.yl4.us-west-2.eks.amazonaws.com`
AWS::ElastiCache::CacheCluster (p. 1386)	`ConfigurationEndpoint.Address`	The DNS address of the configuration endpoint for the Memcached cache cluster. Example: `test.abc12a.cfg.use1.cache.amazonaws.com:11111`
AWS::ElastiCache::CacheCluster (p. 1386)	`ConfigurationEndpoint.Port`	The port number of the configuration endpoint for the Memcached cache cluster.
AWS::ElastiCache::CacheCluster (p. 1386)	`RedisEndpoint.Address`	The DNS address of the configuration endpoint for the Redis cache cluster. Example: `test.abc12a.cfg.use1.cache.amazonaws.com:11111`
AWS::ElastiCache::CacheCluster (p. 1386)	`RedisEndpoint.Port`	The port number of the configuration endpoint for the Redis cache cluster.
AWS::ElastiCache::ReplicationGroup (p. 1395)	`ConfigurationEndpoint.Address`	The DNS hostname of the cache node.
AWS::ElastiCache::ReplicationGroup (p. 1395)	`ConfigurationEndpoint.Port`	The port number that the cache engine is listening on.
AWS::ElastiCache::ReplicationGroup (p. 1395)	`PrimaryEndPoint.Address`	The DNS address of the primary read-write cache node.
AWS::ElastiCache::ReplicationGroup (p. 1395)	`PrimaryEndPoint.Port`	The port number that the primary read-write cache engine is listening on.
AWS::ElastiCache::ReplicationGroup (p. 1395)	`ReadEndPoint.Addresses`	A string with a list of endpoints for the read-only replicas. The order of the addresses maps to the order of the ports from the `ReadEndPoint.Ports` attribute. Example: `"[abc12xmy3d1w3hv6-001.rep12a.0001.use1.cache.amazonaws abc12xmy3d1w3hv6-002.rep12a.0001.use1.cache.amazonaws.c abc12xmy3d1w3hv6-003.rep12a.0001.use1.cache.amazonaws.c`
AWS::ElastiCache::ReplicationGroup (p. 1395)	`ReadEndPoint.Ports`	A string with a list of ports for the read-only replicas. The order of the ports maps to the order of the addresses from the `ReadEndPoint.Addresses` attribute. Example: `"[6379, 6379, 6379]"`
AWS::ElastiCache::ReplicationGroup (p. 1395)	`ReadEndPoint.Addresses.List`	A list of endpoints for the read-only replicas. Example: `["abc12xmy3d1w3hv6-001.rep12a.0001.use1.cache.amazonaws "abc12xmy3d1w3hv6-002.rep12a.0001.use1.cache.amazonaws. "abc12xmy3d1w3hv6-003.rep12a.0001.use1.cache.amazonaws.`

Resource TypeName	Attribute	Description
AWS::ElastiCache::ReplicationGroup (p. 1395)	`ReadEndPoint.Port`	A list of ports for the read-only replicas. Example: `["6379","6379","6379"]`
AWS::ElasticBeanstalk::Environment (p. 1438)	`EndpointURL`	The URL to the load balancer for this environment. Example: `awseb-myst-myen-132MQC4KRLAMD-1371280482.us-east-2.elb.amazonaws.com`
AWS::ElasticLoadBalancingLoadBalancer (p. 1452)	`CanonicalHostedZoneName`	The name of the Route 53-hosted zone that is associated with the load balancer. Example: `mystack-myelb-15HMABG9ZCN57-1013119603.us-east-2.elb.amazonaws.com`
AWS::ElasticLoadBalancingLoadBalancer (p. 1452)	`CanonicalHostedZoneNameID`	The ID of the Route 53 hosted zone name that is associated with the l oad balancer. Example: `Z3DZXE0Q79N41H`
AWS::ElasticLoadBalancingLoadBalancer (p. 1452)	`DNSName`	The DNS name for the load balancer. Example: `mystack-myelb-15HMABG9ZCN57-1013119603.us-east-2.elb.amazonaws.com`
AWS::ElasticLoadBalancingLoadBalancer (p. 1452)	`SourceSecurityGroup.GroupName`	The security group that you can use as part of your inbound rules for your load balancer's back-end Amazon EC2 application instances. Example: `amazon-elb`
AWS::ElasticLoadBalancingLoadBalancer (p. 1452)	`SourceSecurityGroup.OwnerAlias`	The owner of the source security group. Example: `amazon-elb-sg`
AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484)	`DNSName`	The DNS name for the application load balancer. Example: `my-load-balancer-424835706.us-west-2.elb.amazonaws.com`
AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484)	`CanonicalHostedZoneID`	The ID of the Amazon Route 53-hosted zone name that is associated with the load balancer. Example: `Z2P70J7EXAMPLE`
AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484)	`LoadBalancerFullName`	The full name of the application load balancer. Example: `app/my-load-balancer/50dc6c495c0c9188`
AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484)	`LoadBalancerName`	The name of the application load balancer. Example: `my-load-balancer`

Resource TypeName	Attribute	Description
AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1384)	`SecurityGroups`	The IDs of the security groups for the application load balancer. Example: `sg-123456a`
AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491)	`LoadBalancerArns`	The Amazon Resource Names (ARNs) of the load balancers that route traffic to this target group. Example: `[ "arn:aws:elasticloadbalancing:us-west-2:123456789012:loadbalancer/app/my-load-balancer/50dc6c495c0c9188" ]`
AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491)	`TargetGroupFullName`	The full name of the target group. Example: `targetgroup/my-target-group/cbf133c568e0d028`
AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491)	`TargetGroupName`	The name of the target group. Example: `my-target-group`
AWS::Elasticsearch::Domain (p. 1412)	`DomainArn`	The Amazon Resource Name (ARN) of the domain. Example: `arn:aws:es:us-west-2:123456789012:domain/mystack-elasti-1ab2cdefghij`
AWS::Elasticsearch::Domain (p. 1412)	`DomainEndpoint`	The domain-specific endpoint that is used to submit index, search, and data upload requests to an Amazon Elasticsearch Service domain. Example: `search-mystack-elasti-1ab2cdefghij-ab1c2deckoyb3hofw7wpqa3cm.us-west-2.es.amazonaws.com`
AWS::EMR::Cluster (p. 1501)	`MasterPublicDNS`	The public DNS name of the master node (instance). Example: `ec2-12-123-123-123.us-west-2.compute.amazonaws.com`
AWS::Events::Rule (p. 882)	`Arn`	Example: `arn:aws:events:us-east-2:123456789012:rule/example`
AWS::IAM::AccessKey (p. 1657)	`SecretAccessKey`	The secret access key for the specified `Access Key`. Example: `wJalrXUtnFEMI/K7MDENG/bPxRfiCYzEXAMPLEKEY`
AWS::IAM::Group (p. 1658)	`Arn`	Example: `arn:aws:iam::123456789012:group/mystack-mygroup-1DZETITOWEKVO`
AWS::IAM::InstanceProfile (p. 1660)	`Arn`	Example: `arn:aws:iam::1234567890:instance-profile/MyProfile-ASDNSDLKJ`
AWS::IAM::Role (p. 1670)	`Arn`	Example: `arn:aws:iam::1234567890:role/MyRole-AJJHDSKSDF`

Resource TypeName	Attribute	Description
AWS::IAM::User (p. 1678)	Arn	Example: `arn:aws:iam::123456789012:user/mystack-myuser-1CCXAFG2H2U4D`
AWS::IoT::Certificate (p. 1689)	Arn	Example: `arn:aws:iot:ap-southeast-2:123456789012:cert/a1234567b89c012d3e4fg567hij8k9l01mno1p23q45678901rs2345`
AWS::IoT::Policy (p. 1691)	Arn	Example: `arn:aws:iot:us-east-2:123456789012:policy/MyIoTPolicy`
AWS::IoT::TopicRule (p. 1699)	Arn	Example: `arn:aws:iot:us-east-2:123456789012:rule/MyIoTRule`
AWS::IoT1Click::Device (p. 1718)	Arn	The ARN of the AWS IoT 1-Click compatible device. Example: `arn:aws:iot1click:us-west-2:123456789012:devices/G030PX0312744DWM`
AWS::IoT1Click::Device (p. 1718)	DeviceId	The user specified device ID. Example: `G030PX0312744DWM`
AWS::IoT1Click::Device (p. 1718)	Enabled	A Boolean value indicating if the device is enabled (`true`) or disabled (`false`). Example: `true`
AWS::IoT1Click::Placement (p. 1720)	PlacementName	The placement name associated with a project. Example: `region27`
AWS::IoT1Click::Placement (p. 1720)	ProjectName	The name of the project for a given placement. Example: `seattle-region`
AWS::IoT1Click::Project (p. 1723)	ProjectName	The name of the project. Example: `seattle-region`
AWS::IoT1Click::Project (p. 1723)	Arn	The ARN of the project. Example: `arn:aws:iot1click:us-east-1:123456789012:projects/seattle-region`
AWS::Kinesis::Stream (p. 1727)	Arn	Example: `arn:aws:kinesis:us-east-2:123456789012:stream/stream-name`
AWS::KinesisFirehose::DeliveryStream (p. 1730)	Arn	Example: `arn:aws:firehose:us-east-2:123456789012:deliverystream/delivery-stream-name`
AWS::KMS::Key (p. 1788)	Arn	Example: `arn:aws:kms:us-west-2:123456789012:key/12a34567-8c90-1defg-af84-0bf06c1747f3`
AWS::Lambda::Function (p. 1800)	Arn	Example: `arn:aws:lambda:us-west-2:123456789012:MyStack-AMILookUp-NT5EUXTNTXXD`

Resource TypeName	Attribute	Description
AWS::Lambda::Version (p. 1816)	`Version`	The version of a Lambda function. Example: `1`
AWS::Logs::Destination (p. 899)	`Arn`	Example: `arn:aws:logs:us-east-2:123456789012:destination:MyDestination`
AWS::Logs::LogGroup (p. 902)	`Arn`	Example: `arn:aws:logs:us-east-2:123456789012:log-group:/mystack-testgroup-12ABC1AB12A1:*`
AWS::OpsWorks::Instance (p. 1841)	`AvailabilityZone`	The Availability Zone of an AWS OpsWorks instance. Example: `us-east-2a`.
AWS::OpsWorks::Instance (p. 1841)	`PrivateDnsName`	The private DNS name of an AWS OpsWorks instance.
AWS::OpsWorks::Instance (p. 1841)	`PrivateIp`	The private IP address of an AWS OpsWorks instance.
AWS::OpsWorks::Instance (p. 1841)	`PublicDnsName`	The public DNS name of an AWS OpsWorks instance.
AWS::OpsWorks::Instance (p. 1841)	`PublicIp`	The public IP address of an AWS OpsWorks instance. **Note** To use this attribute, the AWS OpsWorks instance must be in an AWS OpsWorks layer that auto-assigns public IP addresses. Example: `192.0.2.0`
AWS::OpsWorks::UserProfile (p. 1882)	`SshUserName`	The SSH user name of an AWS OpsWorks instance.
AWS::Redshift::Cluster (p. 1935)	`Endpoint.Address`	The connection endpoint for the cluster. Example: `examplecluster.cg034hpkmmjt.us-east-2.redshift.amazonaws.com`
AWS::Redshift::Cluster (p. 1935)	`Endpoint.Port`	The connection port for the cluster. Example: `5439`
AWS::RDS::DBCluster (p. 1987)	`Endpoint.Address`	The connection endpoint for the DB cluster. Example: `mystack-mydbcluster-1apw1j4phylrk.cg034hpkmmjt.us-east-2.rds.amazonaws.com`
AWS::RDS::DBCluster (p. 1987)	`Endpoint.Port`	The port number on which the DB cluster accepts connections. Example: `3306`
AWS::RDS::DBCluster (p. 1987)	`ReadEndpoint.Address`	The reader endpoint for the DB cluster. Example: `mystack-mydbcluster-ro-1apw1j4phylrk.cg034hpkmmjt.us-east-2.rds.amazonaws.com`

Resource TypeName	Attribute	Description
AWS::RDS::DBInstance (p. 1998)	`Endpoint.Address`	The connection endpoint for the database. Example: `mystack-mydb-1apw1j4phylrk.cg034hpkmmjt.us-east-2.rds.amazonaws.com`
AWS::RDS::DBInstance (p. 1998)	`Endpoint.Port`	The port number on which the database accepts connections. Example: `3306`
AWS::Route53::HostedZone (p. 1960)	`NameServers`	The set of name servers for the specific hosted zone. Example: `ns1.example.com` This attribute is not supported for private hosted zones.
AWS::S3::Bucket (p. 1985)	`Arn`	Example: `arn:aws:s3:::mybucket`
AWS::S3::Bucket (p. 1985)	`DomainName`	The DNS name of the specified bucket. Example: `mystack-mybucket-kdwwxmddtr2g.s3.amazonaws.com`
AWS::S3::Bucket (p. 1985)	`DualStackDomainName`	The IPv6 DNS name of the specified bucket. Example: `mystack-mybucket-kdwwxmddtr2g.s3.dualstack.us-east-2.amazonaws.com/`
AWS::S3::Bucket (p. 1985)	`WebsiteURL`	The Amazon S3 website endpoint for the specified bucket. Example: `http://mystack-mybucket-kdwwxmddtr2g.s3-website-us-east-2.amazonaws.com/`
AWS::Serverless::Function (p. 194)	`Arn`	The ARN of an `AWS::Serverless::Function` resource.
AWS::ServiceDiscovery::PrivateDnsNamespace (p. 1976)	`Id`	Example: `ns-t2kl4fs6xexample`
AWS::ServiceDiscovery::PrivateDnsNamespace (p. 1976)	`Arn`	Example: `arn:aws:servicediscovery:us-west-2:1234567890:namespace/ns-t2kl4fs6xexample`
AWS::ServiceDiscovery::PublicDnsNamespace (p. 1978)	`Id`	Example: `ns-d6wz3hq6kexample`
AWS::ServiceDiscovery::PublicDnsNamespace (p. 1978)	`Arn`	Example: `arn:aws:servicediscovery:us-west-2:1234567890:namespace/ns-d6wz3hq6kexample`
AWS::ServiceDiscovery::Service (p. 1979)	`Id`	Example: `srv-7dfj3r6cyexample`
AWS::ServiceDiscovery::Service (p. 1979)	`Arn`	Example: `arn:aws:servicediscovery:us-west-2:1234567890:service/srv-7dfj3r6cyexample`
AWS::ServiceDiscovery::Service (p. 1979)	`Name`	Example: `example`

Resource TypeName	Attribute	Description
AWS::SNS::Topic (p. 2128)	TopicName	The name of an Amazon SNS topic. Example: my-sns-topic
AWS::StepFunctions::Activity (p. 2142)	Name	The name of the AWS Step Functions activity.
AWS::StepFunctions::StateMachine (p. 2144)	Name	The name of the Step Functions state machine.
AWS::SQS::Queue (p. 2133)	Arn	Example: arn:aws:sqs:us-east-2:123456789012:mystack-myqueue-15PG5C2FC1CW8
AWS::SQS::Queue (p. 2133)	QueueName	The name of an Amazon SQS queue. Example: mystack-myqueue-1VF9BKQH5BJVI

Fn::GetAZs

The intrinsic function Fn::GetAZs returns an array that lists Availability Zones for a specified region. Because customers have access to different Availability Zones, the intrinsic function Fn::GetAZs enables template authors to write templates that adapt to the calling user's access. That way you don't have to hard-code a full list of Availability Zones for a specified region.

> **Important**
> For the EC2-Classic platform, the Fn::GetAZs function returns all Availability Zones for a region. For the EC2-VPC platform, the Fn::GetAZs function returns only Availability Zones that have a default subnet unless none of the Availability Zones has a default subnet; in that case, all Availability Zones are returned.
> Similarly to the response from the describe-availability-zones AWS CLI command, the order of the results from the Fn::GetAZs function is not guaranteed and can change when new Availability Zones are added.

IAM permissions

The permissions that you need in order to use the Fn::GetAZs function depend on the platform in which you're launching Amazon EC2 instances. For both platforms, you need permissions to the Amazon EC2 DescribeAvailabilityZones and DescribeAccountAttributes actions. For EC2-VPC, you also need permissions to the Amazon EC2 DescribeSubnets action.

Declaration

JSON

```
{ "Fn::GetAZs" : "region" }
```

YAML

Syntax for the full function name:

```
Fn::GetAZs: region
```

Syntax for the short form:

```
!GetAZs region
```

Parameters

region

The name of the region for which you want to get the Availability Zones.

You can use the `AWS::Region` pseudo parameter to specify the region in which the stack is created. Specifying an empty string is equivalent to specifying `AWS::Region`.

Return Value

The list of Availability Zones for the region.

Examples

Evaluate a Region

For these examples, AWS CloudFormation evaluates `Fn::GetAZs` to the following array—assuming that the user has created the stack in the `us-east-1` region:

```
[ "us-east-1a", "us-east-1b", "us-east-1c", "us-east-1d" ]
```

JSON

```
{ "Fn::GetAZs" : "" }
{ "Fn::GetAZs" : { "Ref" : "AWS::Region" } }
{ "Fn::GetAZs" : "us-east-1" }
```

YAML

```
Fn::GetAZs: ""
Fn::GetAZs:
  Ref: "AWS::Region"
Fn::GetAZs: us-east-1
```

Specify a Subnet's Availability Zone

The following example uses `Fn::GetAZs` to specify a subnet's Availability Zone:

JSON

```
"mySubnet" : {
  "Type" : "AWS::EC2::Subnet",
  "Properties" : {
    "VpcId" : {
      "Ref" : "VPC"
    },
    "CidrBlock" : "10.0.0.0/24",
    "AvailabilityZone" : {
      "Fn::Select" : [
        "0",
        {
          "Fn::GetAZs" : ""
```

```
        }
      ]
    }
  }
}
```

YAML

```
mySubnet:
  Type: "AWS::EC2::Subnet"
  Properties:
    VpcId:
      !Ref VPC
    CidrBlock: 10.0.0.0/24
    AvailabilityZone:
      Fn::Select:
        - 0
        - Fn::GetAZs: ""
```

Nested Functions with Short Form YAML

The following examples show valid patterns for using nested intrinsic functions using short form YAML. You can't nest short form functions consecutively, so a pattern like `!GetAZs !Ref` is invalid.

YAML

```
AvailabilityZone: !Select
  - 0
  - !GetAZs
    Ref: 'AWS::Region'
```

YAML

```
AvailabilityZone: !Select
  - 0
  - Fn::GetAZs: !Ref 'AWS::Region'
```

Supported Functions

You can use the `Ref` function in the `Fn::GetAZs` function.

`Fn::ImportValue`

The intrinsic function `Fn::ImportValue` returns the value of an output exported (p. 200) by another stack. You typically use this function to create cross-stack references (p. 250). In the following example template snippets, Stack A exports VPC security group values and Stack B imports them.

> **Note**
> The following restrictions apply to cross-stack references:
>
> - For each AWS account, `Export` names must be unique within a region.
> - You can't create cross-stack references across regions. You can use the intrinsic function `Fn::ImportValue` to import only values that have been exported within the same region.

- For outputs, the value of the `Name` property of an `Export` can't use `Ref` or `GetAtt` functions that depend on a resource.

  Similarly, the `ImportValue` function can't include `Ref` or `GetAtt` functions that depend on a resource.
- You can't delete a stack if another stack references one of its outputs.
- You can't modify or remove an output value that is referenced by another stack.

Stack A Export

```
"Outputs" : {
  "PublicSubnet" : {
    "Description" : "The subnet ID to use for public web servers",
    "Value" :  { "Ref" : "PublicSubnet" },
    "Export" : { "Name" : {"Fn::Sub": "${AWS::StackName}-SubnetID" }}
  },
  "WebServerSecurityGroup" : {
    "Description" : "The security group ID to use for public web servers",
    "Value" :  { "Fn::GetAtt" : ["WebServerSecurityGroup", "GroupId"] },
    "Export" : { "Name" : {"Fn::Sub": "${AWS::StackName}-SecurityGroupID" }}
  }
}
```

Stack B Import

```
"Resources" : {
  "WebServerInstance" : {
    "Type" : "AWS::EC2::Instance",
    "Properties" : {
      "InstanceType" : "t2.micro",
      "ImageId" : "ami-a1b23456",
      "NetworkInterfaces" : [{
        "GroupSet" : [{"Fn::ImportValue" : {"Fn::Sub" : "${NetworkStackNameParameter}-
SecurityGroupID"}}],
        "AssociatePublicIpAddress" : "true",
        "DeviceIndex" : "0",
        "DeleteOnTermination" : "true",
        "SubnetId" : {"Fn::ImportValue" : {"Fn::Sub" : "${NetworkStackNameParameter}-
SubnetID"}}
      }]
    }
  }
}
```

Declaration

JSON

```
{ "Fn::ImportValue" : sharedValueToImport }
```

YAML

You can use the full function name:

```
Fn::ImportValue: sharedValueToImport
```

Alternatively, you can use the short form:

```
!ImportValue sharedValueToImport
```

Important
You can't use the short form of `!ImportValue` when it contains a `!Sub`. The following example is valid for AWS CloudFormation, but *not* valid for YAML:

```
!ImportValue
  !Sub "${NetworkStack}-SubnetID"
```

Instead, you must use the full function name, for example:

```
Fn::ImportValue:
  !Sub "${NetworkStack}-SubnetID"
```

Parameters

sharedValueToImport

The stack output value that you want to import.

Return Value

The stack output value.

Example

JSON

```
{ "Fn::ImportValue" : {"Fn::Sub": "${NetworkStackNameParameter}-SubnetID" } }
```

YAML

```
Fn::ImportValue:
  !Sub "${NetworkStackName}-SecurityGroupID"
```

Supported Functions

You can use the following functions in the `Fn::ImportValue` function. The value of these functions can't depend on a resource.

- `Fn::Base64`
- `Fn::FindInMap`
- `Fn::If`
- `Fn::Join`
- `Fn::Select`
- `Fn::Split`
- `Fn::Sub`
- `Ref`

Fn::Join

The intrinsic function `Fn::Join` appends a set of values into a single value, separated by the specified delimiter. If a delimiter is the empty string, the set of values are concatenated with no delimiter.

Declaration

JSON

```
{ "Fn::Join" : [ "delimiter", [ comma-delimited list of values ] ] }
```

YAML

Syntax for the full function name:

```
Fn::Join: [ delimiter, [ comma-delimited list of values ] ]
```

Syntax for the short form:

```
!Join [ delimiter, [ comma-delimited list of values ] ]
```

Parameters

delimiter

The value you want to occur between fragments. The delimiter will occur between fragments only. It will not terminate the final value.

ListOfValues

The list of values you want combined.

Return Value

The combined string.

Examples

Join a Simple String Array

The following example returns: `"a:b:c"`.

JSON

```
"Fn::Join" : [ ":", [ "a", "b", "c" ] ]
```

YAML

```
!Join [ ":", [ a, b, c ] ]
```

Join Using the Ref Function with Parameters

The following example uses `Fn::Join` to construct a string value. It uses the `Ref` function with the `Partition` parameter and the `AWS::AccountId` pseudo parameter.

JSON

```
{
  "Fn::Join": [
    "", [
      "arn:",
      {
        "Ref": "Partition"
      },
      ":s3:::elasticbeanstalk-*-",
      {
        "Ref": "AWS::AccountId"
      }
    ]
  ]
}
```

YAML

```
!Join
  - ''
  - - 'arn:'
    - !Ref Partition
    - ':s3:::elasticbeanstalk-*-'
    - !Ref 'AWS::AccountId'
```

Note
Also see the `Fn::Sub` (p. 2337) function for similar functionality.

Supported Functions

For the `Fn::Join` delimiter, you cannot use any functions. You must specify a string value.

For the `Fn::Join` list of values, you can use the following functions:

- `Fn::Base64`
- `Fn::FindInMap`
- `Fn::GetAtt`
- `Fn::GetAZs`
- `Fn::If`
- `Fn::ImportValue`
- `Fn::Join`
- `Fn::Split`
- `Fn::Select`
- `Fn::Sub`
- `Ref`

Fn::Select

The intrinsic function `Fn::Select` returns a single object from a list of objects by index.

Important
Fn::Select does not check for null values or if the index is out of bounds of the array. Both conditions will result in a stack error, so you should be certain that the index you choose is valid, and that the list contains non-null values.

Declaration

JSON

```
{ "Fn::Select" : [ index, listOfObjects ] }
```

YAML

Syntax for the full function name:

```
Fn::Select: [ index, listOfObjects ]
```

Syntax for the short form:

```
!Select [ index, listOfObjects ]
```

Parameters

index

The index of the object to retrieve. This must be a value from zero to N-1, where N represents the number of elements in the array.

listOfObjects

The list of objects to select from. This list must not be null, nor can it have null entries.

Return Value

The selected object.

Examples

Basic Example

The following example returns: `"grapes"`.

JSON

```
{ "Fn::Select" : [ "1", [ "apples", "grapes", "oranges", "mangoes" ] ] }
```

YAML

```
!Select [ "1", [ "apples", "grapes", "oranges", "mangoes" ] ]
```

Comma-delimited List Parameter Type

You can use `Fn::Select` to select an object from a `CommaDelimitedList` parameter. You might use a `CommaDelimitedList` parameter to combine the values of related parameters, which reduces the total number of parameters in your template. For example, the following parameter specifies a comma-delimited list of three CIDR blocks:

JSON

```
"Parameters" : {
  "DbSubnetIpBlocks": {
    "Description": "Comma-delimited list of three CIDR blocks",
    "Type": "CommaDelimitedList",
      "Default": "10.0.48.0/24, 10.0.112.0/24, 10.0.176.0/24"
  }
}
```

YAML

```
Parameters:
  DbSubnetIpBlocks:
    Description: "Comma-delimited list of three CIDR blocks"
    Type: CommaDelimitedList
    Default: "10.0.48.0/24, 10.0.112.0/24, 10.0.176.0/24"
```

To specify one of the three CIDR blocks, use `Fn::Select` in the Resources section of the same template, as shown in the following sample snippet:

JSON

```
"Subnet0": {
  "Type": "AWS::EC2::Subnet",
    "Properties": {
      "VpcId": { "Ref": "VPC" },
      "CidrBlock": { "Fn::Select" : [ "0", {"Ref": "DbSubnetIpBlocks"} ] }
    }
}
```

YAML

```
Subnet0:
  Type: "AWS::EC2::Subnet"
  Properties:
    VpcId: !Ref VPC
    CidrBlock: !Select [ 0, !Ref DbSubnetIpBlocks ]
```

Nested Functions with Short Form YAML

The following examples show valid patterns for using nested intrinsic functions with the `!Select` short form. You can't nest short form functions consecutively, so a pattern like `!GetAZs !Ref` is invalid.

YAML

```
AvailabilityZone: !Select
  - 0
  - !GetAZs
    Ref: 'AWS::Region'
```

YAML

```
AvailabilityZone: !Select
  - 0
  - Fn::GetAZs: !Ref 'AWS::Region'
```

Supported Functions

For the `Fn::Select` index value, you can use the `Ref` and `Fn::FindInMap` functions.

For the `Fn::Select` list of objects, you can use the following functions:

- `Fn::FindInMap`
- `Fn::GetAtt`
- `Fn::GetAZs`
- `Fn::If`
- `Fn::Split`
- `Ref`

Fn::Split

To split a string into a list of string values so that you can select an element from the resulting string list, use the `Fn::Split` intrinsic function. Specify the location of splits with a delimiter, such as `,` (a comma). After you split a string, use the `Fn::Select` (p. 2332) function to pick a specific element.

For example, if a comma-delimited string of subnet IDs is imported to your stack template, you can split the string at each comma. From the list of subnet IDs, use the `Fn::Select` intrinsic function to specify a subnet ID for a resource.

Declaration

JSON

```
{ "Fn::Split" : [ "delimiter", "source string" ] }
```

YAML

Syntax for the full function name:

```
Fn::Split: [ delimiter, source string ]
```

Syntax for the short form:

```
!Split [ delimiter, source string ]
```

Parameters

You must specify both parameters.

delimiter

A string value that determines where the source string is divided.

source string

The string value that you want to split.

Return Value

A list of string values.

Examples

The following examples demonstrate the behavior of the `Fn::Split` function.

Simple List

The following example splits a string at each vertical bar (`|`). The function returns `["a", "b", "c"]`.

JSON

```
{ "Fn::Split" : [ "|" , "a|b|c" ] }
```

YAML

```
!Split [ "|" , "a|b|c" ]
```

List with Empty String Values

If you split a string with consecutive delimiters, the resulting list will include an empty string. The following example shows how a string with two consecutive delimiters and an appended delimiter is split. The function returns `["a", "", "c", ""]`.

JSON

```
{ "Fn::Split" : [ "|" , "a||c|" ] }
```

YAML

```
!Split [ "|" , "a||c|" ]
```

Split an Imported Output Value

The following example splits an imported output value, and then selects the third element from the resulting list of subnet IDs, as specified by the `Fn::Select` function.

JSON

```
{ "Fn::Select" : [ "2", { "Fn::Split": [",", {"Fn::ImportValue": "AccountSubnetIDs"}]}] }
```

YAML

```
!Select [2, !Split [",", !ImportValue AccountSubnetIDs]]
```

Supported Functions

For the `Fn::Split` delimiter, you cannot use any functions. You must specify a string value.

For the `Fn::Split` list of values, you can use the following functions:

- `Fn::Base64`
- `Fn::FindInMap`

- Fn::GetAtt
- Fn::GetAZs
- Fn::If
- Fn::ImportValue
- Fn::Join
- Fn::Select
- Fn::Sub
- Ref

Fn::Sub

The intrinsic function Fn::Sub substitutes variables in an input string with values that you specify. In your templates, you can use this function to construct commands or outputs that include values that aren't available until you create or update a stack.

Declaration

The following sections show the function's syntax.

JSON

```
{ "Fn::Sub" : [ String, { Var1Name: Var1Value, Var2Name: Var2Value } ] }
```

If you're substituting only template parameters, resource logical IDs, or resource attributes in the *String* parameter, don't specify a variable map.

```
{ "Fn::Sub" : String }
```

YAML

Syntax for the full function name:

```
Fn::Sub:
  - String
  - { Var1Name: Var1Value, Var2Name: Var2Value }
```

Syntax for the short form:

```
!Sub
  - String
  - { Var1Name: Var1Value, Var2Name: Var2Value }
```

If you're substituting only template parameters, resource logical IDs, or resource attributes in the *String* parameter, don't specify a variable map.

Syntax for the full function name:

```
Fn::Sub: String
```

Syntax for the short form:

```
!Sub String
```

Parameters

`String`

A string with variables that AWS CloudFormation substitutes with their associated values at runtime. Write variables as `${MyVarName}`. Variables can be template parameter names, resource logical IDs, resource attributes, or a variable in a key-value map. If you specify only template parameter names, resource logical IDs, and resource attributes, don't specify a key-value map.

If you specify template parameter names or resource logical IDs, such as `${InstanceTypeParameter}`, AWS CloudFormation returns the same values as if you used the `Ref` intrinsic function. If you specify resource attributes, such as `${MyInstance.PublicIp}`, AWS CloudFormation returns the same values as if you used the `Fn::GetAtt` intrinsic function.

To write a dollar sign and curly braces (`${}`) literally, add an exclamation point (`!`) after the open curly brace, such as `${!Literal}`. AWS CloudFormation resolves this text as `${Literal}`.

`VarName`

The name of a variable that you included in the `String` parameter.

`VarValue`

The value that AWS CloudFormation substitutes for the associated variable name at runtime.

Return Value

AWS CloudFormation returns the original string, substituting the values for all of the variables.

Examples

The following examples demonstrate how to use the `Fn::Sub` function.

Fn::Sub with a Mapping

The following example uses a mapping to substitute the `${Domain}` variable with the resulting value from the `Ref` function.

JSON

```
{ "Fn::Sub": [ "www.${Domain}", { "Domain": {"Ref" : "RootDomainName" }} ]}
```

YAML

```
Name: !Sub
  - www.${Domain}
  - { Domain: !Ref RootDomainName }
```

Fn::Sub without a Mapping

The following example uses Fn::Sub with the `AWS::Region` and `AWS::AccountId` pseudo parameters and the `vpc` resource logical ID to create an Amazon Resource Name (ARN) for a VPC.

JSON

```
{ "Fn::Sub": "arn:aws:ec2:${AWS::Region}:${AWS::AccountId}:vpc/${vpc}" }
```

YAML

```
!Sub 'arn:aws:ec2:${AWS::Region}:${AWS::AccountId}:vpc/${vpc}'
```

UserData Commands

The following example uses `Fn::Sub` to substitute the `AWS::StackName` and `AWS::Region` pseudo parameters for the actual stack name and region at runtime.

JSON

For readability, the JSON example uses the `Fn::Join` function to separate each command, instead of specifying the entire user data script in a single string value.

```
"UserData": { "Fn::Base64": { "Fn::Join": ["\n", [
  "#!/bin/bash -xe",
  "yum update -y aws-cfn-bootstrap",
  { "Fn::Sub": "/opt/aws/bin/cfn-init -v --stack ${AWS::StackName} --resource LaunchConfig
 --configsets wordpress_install --region ${AWS::Region}" },
  { "Fn::Sub": "/opt/aws/bin/cfn-signal -e $? --stack ${AWS::StackName} --resource
 WebServerGroup --region ${AWS::Region}" }]]
}}
```

YAML

The YAML example uses a literal block to specify the user data script.

```
UserData:
  Fn::Base64:
    !Sub |
      #!/bin/bash -xe
      yum update -y aws-cfn-bootstrap
      /opt/aws/bin/cfn-init -v --stack ${AWS::StackName} --resource LaunchConfig --
configsets wordpress_install --region ${AWS::Region}
      /opt/aws/bin/cfn-signal -e $? --stack ${AWS::StackName} --resource WebServerGroup --
region ${AWS::Region}
```

Supported Functions

For the `String` parameter, you cannot use any functions. You must specify a string value.

For the `VarName` and `VarValue` parameters, you can use the following functions:

- `Fn::Base64`
- `Fn::FindInMap`
- `Fn::GetAtt`
- `Fn::GetAZs`
- `Fn::If`
- `Fn::ImportValue`
- `Fn::Join`
- `Fn::Select`
- `Ref`

Fn::Transform

The intrinsic function `Fn::Transform` specifies a macro to perform custom processing on part of a stack template. Macros enable you to perform custom processing on templates, from simple actions like find-and-replace operations to extensive transformations of entire templates. For more information, see Using AWS CloudFormation Macros to Perform Custom Processing on Templates (p. 465).

You can also use `Fn::Transform` to call the `AWS::Include Transform` (p. 195) transform, which is a macro hosted by AWS CloudFormation.

Declaration

JSON

```
{ "Fn::Transform" : { "Name" : macro name, "Parameters" : {key : value, ... } } }
```

YAML

Syntax for the full function name:

```
Fn::Transform:
  Name : macro name
  Parameters :
          Key : value
```

Syntax for the short form:

```
!Transform { "Name" : macro name, "Parameters" : {key : value, ... } }
```

Parameters

Name

The name of the macro you want to perform the processing.

Parameters

The list parameters, specified as key-value pairs, to pass to the macro.

Return Value

The processed template snippet to be included in the processed stack template.

Examples

The following example calls the `AWS::Include` transform, specifying that the location to retrieve a template snippet from is passed in the `InputValue` parameter.

JSON

```
{
   "Fn::Transform" : {
       "Name" : "AWS::Include",
       "Parameters" : {
           "Location" : { "Ref" : "InputValue" }
        }
```

```
    }
}
```

YAML

```
'Fn::Transform':
    Name: 'AWS::Include'
    Parameters: {Location: {Ref: InputValue}}
```

The following example calls the `AWS::Include` transform, specifying that the location to retrieve a template snippet from is located in the `RegionMap` mapping, under the key `us-east-1` and nested key `s3Location`.

JSON

```
{
   "Fn::Transform" : {
       "Name" : "AWS::Include",
       "Parameters" : {
           "Location" : {"Fn::FindInMap" : ["RegionMap", "us-east-1", "s3Location"] }
        }
    }
}
```

YAML

```
'Fn::Transform':
    Name: 'AWS::Include'
    Parameters: {Location: {'Fn::FindInMap': [RegionMap, us-east-1, s3Location]}}
```

Supported Functions

None. AWS CloudFormation passes any intrinsic function calls included in `Fn::Transform` to the specified macro as literal strings. For more information, see AWS CloudFormation Macro Function Interface (p. 466).

Ref

The intrinsic function `Ref` returns the value of the specified *parameter* or *resource*.

- When you specify a parameter's logical name, it returns the value of the parameter.
- When you specify a resource's logical name, it returns a value that you can typically use to refer to that resource, such as a physical ID (p. 197).

When you are declaring a resource in a template and you need to specify another template resource by name, you can use the `Ref` to refer to that other resource. In general, `Ref` returns the name of the resource. For example, a reference to an AWS::AutoScaling::AutoScalingGroup (p. 699) returns the name of that Auto Scaling group resource.

For some resources, an identifier is returned that has another significant meaning in the context of the resource. An AWS::EC2::EIP (p. 1144) resource, for instance, returns the IP address, and an AWS::EC2::Instance (p. 1155) returns the instance ID.

At the bottom of this topic, there is a table that lists the values returned for many common resource types. More information about `Ref` return values for a particular resource or property can be found in the documentation for that resource or property.

Tip
You can also use `Ref` to add values to Output messages.

Declaration

JSON

```
{ "Ref" : "logicalName" }
```

YAML

Syntax for the full function name:

```
Ref: logicalName
```

Syntax for the short form:

```
!Ref logicalName
```

Parameters

logicalName

The logical name of the resource or parameter you want to dereference.

Return Value

The physical ID of the resource or the value of the parameter.

Example

The following resource declaration for an Elastic IP address needs the instance ID of an EC2 instance and uses the `Ref` function to specify the instance ID of the MyEC2Instance resource:

JSON

```
"MyEIP" : {
   "Type" : "AWS::EC2::EIP",
   "Properties" : {
      "InstanceId" : { "Ref" : "MyEC2Instance" }
   }
}
```

YAML

```
MyEIP:
  Type: "AWS::EC2::EIP"
  Properties:
    InstanceId: !Ref MyEC2Instance
```

Supported Functions

You cannot use any functions in the `Ref` function. You must specify a string that is a resource logical ID.

Resource Return Examples

This section lists sample values returned by `Ref` for particular AWS CloudFormation resources. For more information about `Ref` return values for a particular resource or property, refer to the documentation for that resource or property.

Resource Type	Reference Value	Example Return Value
AWS::AmazonMQ::Broker (p. 520)	Amazon MQ broker ID	`b-1234a5b6-78cd-901e-2fgh-3i45j6k178l9`
AWS::AmazonMQ::Configuration (p. 530)	Amazon MQ configuration ID	`c-1234a5b6-78cd-901e-2fgh-3i45j6k178l9`
AWS::ApiGateway::Account (p. 534)	API Gateway account resource ID	`mysta-accou-01234b567890example`
AWS::ApiGateway::ApiKey (p. 536)	API key	`m2m1k7sybf`
AWS::ApiGateway::Authorizer (p. 540)	Authorizer resource ID	`abcde1`
AWS::ApiGateway::ClientCertificate (p. 545)	Client certificate name	`abc123`
AWS::ApiGateway::Deployment (p. 547)	Deployment resource ID	`abc123`
AWS::ApiGateway::DomainName (p. 566)	Domain name	`example.mydomain.com`
AWS::ApiGateway::Method (p. 573)	Method resource ID	`mysta-metho-01234b567890example`
AWS::ApiGateway::Model (p. 590)	Model name	`myModel`
AWS::ApiGateway::Resource (p. 596)	API Gateway resource ID	`abc123`
AWS::ApiGateway::RestApi (p. 598)	Rest API resource ID	`a1bcdef2gh`
AWS::ApiGateway::Stage (p. 606)	Stage name	`MyTestStage`
AWS::ApplicationAutoScaling::ScalableTarget (p. 624)	Scalable Target ID	`service/ecsStack-MyECSCluster-AB12CDE3F4GH/ecsStack-MyECSService-AB12CDE3F4GH|ecs:service:DesiredCount|ecs`
AWS::ApplicationAutoScaling::ScalingPolicy (p. 639)	Application Auto Scaling policy Amazon Resource Name (ARN)	`arn:aws:autoscaling:us-east-1:123456789012:scalingPolicy:12ab ecs/service/ecsStack-MyECSCluster-AB12CDE3F4GH/ecsStack-MyECSService-AB12CDE3F4GH:policyName/MyStepPolicy`
AWS::Athena::NamedQuery (p. 697)	Named query name	`abc123`
AWS::AutoScaling::AutoScalingGroup (p. 699)	Name	`mystack-myasgroup-NT5EUXTNTXXD`
AWS::AutoScaling::LaunchConfiguration (p. 715)	Name	`mystack-mylaunchconfig-1DDYF1E3B3I`
AWS::AutoScaling::LifecycleHook (p. 726)	Name	`mylifecyclehookname`

Resource Type	Reference Value	Example Return Value
AWS::AutoScaling::ScalingPolicy (p. 728)	Scaling policy Amazon Resource Name (ARN)	arn:aws:autoscaling:us-east-1:123456789012:scalingPolicy:ab12c a1b2-a1b2-a1b2-ab12c4d56789:autoScalingGroupName/myStack-AutoScalingGroup-AB12C4D5E6:policyName/myStack-myScalingPolicy-AB12C4D5E6
AWS::AutoScaling::ScheduledAction (p. 741)	Name	mystack-myscheduledaction-NT5EUXTNTXXD
AWS::Batch::ComputeEnvironment (p. 753)	AWS Batch Compute Environment Amazon Resource Name (ARN)	arn:aws:batch:*us-east-1*:*555555555555*:compute-environment/*M4OnDemand*
AWS::Batch::JobDefinition (p. 760)	AWS Batch Job Definition Amazon Resource Name (ARN)	arn:aws:batch:*us-east-1*:*111122223333*:job-definition/*test-gpu*:*2*
AWS::Batch::JobQueue (p. 763)	AWS Batch Job Queue Amazon Resource Name (ARN)	arn:aws:batch:*us-east-1*:*111122223333*:job-queue/*HighPriority*
AWS::CertificateManager::Certificate (p. 768)	Certificate Amazon Resource Name (ARN)	arn:aws:acm:us-east-1:123456789012:certificate/12ab3c
AWS::Cloud9::EnvironmentEC2 (p. 791)	Development environment ID	2bc3642873c342e485f7e0c56example
AWS::CloudFormation::Stack (p. 823)	Stack ID	arn:aws:cloudformation:us-east-2:803981987763:stack/mystack-mynestedstack-sggfrhxhum7w/f449b250-b969-11e0-a185-5081d0136786

AWS::CloudFormation::WaitConditionHandle (p. 830)	Wait Condition Signal URL	https://cloudformation-waitcondition-us-east-2.s3.amazonaws.com/arn%3Aaws%3Acloudformation%3Aus-east-2%3A803981987763%3Astack%2Fwaittest%2F054a33d0-bdee-11e0-8816-5081c490a786%2FmyWaitHa Expires=1312475488&AWSAccessKeyId=AKIA %3D
AWS::CloudFront::Distribution (p. 831)	Distribution ID	E27LVI50CSW06W
AWS::CloudTrail::Trail (p. 865)	Trail name	awscloudtrail-example

Resource Type	Reference Value	Example Return Value
AWS::CloudWatch::Alarm (p. 874)	Name	mystack-myalarm-3AOHFRGOXR5T
AWS::CodeBuild::Project (p. 911)	Project name	myProjectName
AWS::CodeCommit::Repository (p. 991)	Repository ID	12a345b6-bbb7-4bb6-90b0-8c9577a2d2b9
AWS::CodeDeploy::Application (p. 935)	Application name	myapplication-a123d0d1
AWS::CodeDeploy::DeploymentConfig (p. 937)	Deployment configuration name	mydeploymentconfig-a123d0d1
AWS::CodeDeploy::DeploymentGroup (p. 940)	Deployment group name	mydeploymentgroup-a123d0d1
AWS::CodePipeline::CustomActionType (p. 973)	Custom action name	mysta-MyCus-A1BCDEFGHIJ2
AWS::CodePipeline::Pipeline (p. 979)	Pipeline name	mysta-MyPipeline-A1BCDEFGHIJ2
AWS::CodePipeline::Webhook (p. 991)	Webhook name	MyFirstPipeline-SourceAction1-Webhook-utb9LrOl24Kk
AWS::Config::ConfigRule (p. 1037)	Configuration rule name	mystack-MyConfigRule-12ABCFPXHV4OV
AWS::Config::ConfigurationRecorder (p. 1050)	Configuration recorder name	default
AWS::Config::DeliveryChannel (p. 1053)	Delivery channel name	default
AWS::DataPipeline::Pipeline (p. 1056)	Pipeline ID	df-sample322HVPGK130TOD
AWS::DAX::Cluster (p. 1070)	Name	MyDAXCluster
AWS::DirectoryService::MicrosoftAD (p. 1083)	Microsoft directory ID	d-12345ab592
AWS::DirectoryService::SimpleAD (p. 1087)	Directory ID	d-12345ab592
AWS::DynamoDB::Table (p. 1110)	Table Name	MyDDBTable
AWS::EC2::EIP (p. 1144)	Elastic IP Address	192.0.2.0
AWS::EC2::EIPAssociation (p. 1146)	Name	mystack-myeipa-1NU3IL8LJ313N
AWS::EC2::FlowLog (p. 1150)	Flow log ID	fl-1a23b456
AWS::EC2::Host (p. 1153)	Host ID	h-0ab123c45d67ef89
AWS::EC2::Instance (p. 1155)	Instance ID	i-1234567890abcdef0
AWS::EC2::NatGateway (p. 1199)	NAT gateway ID	nat-0a12bc456789de0fg
AWS::EC2::NetworkInterfacePermission (p. 1216)	Network interface permission ID	eni-perm-055663b682ea24b48
AWS::EC2::PlacementGroup (p. 1218)	Placement group name	mystack-myplacementgroup-CU6107MRVLR7
AWS::EC2::RouteTable (p. 1223)	Route table ID	rtb-12a34567

Resource Type	Reference Value	Example Return Value
AWS::EC2::SecurityGroup (p. 1235)	Name or security group ID (for VPC security groups that are not in a default VPC)	`mystack-mysecuritygroup-QQB406M8FISX or sg-94b3a1f6`
AWS::EC2::SecurityGroupIngress (p. 1238)	Name	`mysecuritygroupingress`
AWS::EC2::SpotFleet (p. 1246)	Name	`sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE`
AWS::EC2::Subnet (p. 1250)	Subnet ID	`subnet-e19f0178`
AWS::EC2::Volume (p. 1276)	Volume ID	`vol-3cdd3f56`
AWS::EC2::VolumeAttachment (p. 1283)	Name	`mystack-myvola-ERXHJITXMRLT`
AWS::EC2::VPC (p. 1285)	VPC ID	`vpc-18ac277d`
AWS::EC2::VPCPeeringConnection (p. 1292)	VPC peering connection ID	`pcx-75de3e1d`
AWS::EC2::VPCEndpoint (p. 1293)	Endpoint ID	`vpce-a123d0d1`
AWS::ECR::Repository (p. 1326)	Repository name	`test-repository`
AWS::ECS::Cluster (p. 1337)	Name	`MyStack-MyECSCluster-NT5EUXTNTXXD`
AWS::ECS::Service (p. 1352)	Service ARN	`arn:aws:ecs:us-west-2:123456789012:service/sample-webapp`
AWS::ECS::TaskDefinition (p. 1365)	Task definition ARN	`arn:aws:ecs:us-west-2:123456789012:task-definition/TaskDefinitionFamily:1`
AWS::EFS::FileSystem (p. 1375)	File system ID	`fs-47a2c22e`
AWS::EFS::MountTarget (p. 1378)	Mount target ID	`fsmt-55a4413c`
AWS::EKS::Cluster (p. 1383)	Name	`EKSCluster-NT5EUXTNTXXD`
AWS::ElastiCache::ReplicationGroup (p. 1395)	Name	`abc12xmy3d1w3hv6`
AWS::ElastiCache::SubnetGroup (p. 1410)	Name	`myCachesubnetgroup`
AWS::ElasticLoadBalancingV2::Listener (p. 1433)	Listener's Amazon Resource Name (ARN)	`arn:aws:elasticloadbalancing:us-west-2:123456789012:listener/app/my-load-balancer/50dc6c495c0c9188/f2f7dc8efc522ab2`
AWS::ElasticLoadBalancingV2::ListenerRule (p. 1480)	Listener rule's Amazon Resource Name (ARN)	`arn:aws:elasticloadbalancing:us-west-2:123456789012:listener-rule/app/my-load-balancer/50dc6c495c0c9188/f2f7dc8efc522ab2/9683b2d02a6cabee`

Resource Type	Reference Value	Example Return Value
AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484)	Application load balancer's Amazon Resource Name (ARN)	`arn:aws:elasticloadbalancing:us-west-2:123456789012:loadbalancer/app/my-internal-load-balancer/50dc6c495c0c9188`
AWS::ElasticLoadBalancingV2::TargetGroup (p. 1493)	Target group's Amazon Resource Name (ARN)	`arn:aws:elasticloadbalancing:us-west-2:123456789012:targetgroup/my-targets/73e2d6bc24d8a067`
AWS::Elasticsearch::Domain (p. 1412)	Domain name	`mystack-elasticsea-abc1d2efg3h4`
AWS::EMR::Cluster (p. 1510)	Cluster ID	`j-1ABCD123AB1A`
AWS::EMR::InstanceGroupConfig (p. 1550)	Instance group ID	`ig-ABC12DEF3456`
AWS::EMR::SecurityConfiguration (p. 1565)	Name	`mySecurityConfiguration`
AWS::EMR::Step (p. 1568)	Step ID	`s-1A2BC3D4EFG56`
AWS::ElasticBeanstalk::Application (p. 1425)	Name	`mystack-myapplication-FM6BIXY7U8PK`
AWS::ElasticBeanstalk::ApplicationVersion (p. 1430)	Name	`mystack-myapplicationversion-iy8ptveuxjly`
AWS::ElasticBeanstalk::ConfigurationTemplate (p. 1433)	Name	`mystack-myconfigurationtemplate-108RPH64J195`
AWS::ElasticBeanstalk::Environment (p. 1438)	Name	`mystack-myenv-LKGNQSFHO1DB`
AWS::ElasticLoadBalancing::LoadBalancer (p. 1452)	Name	`mystack-myelb-1WQN7BJGDB5YQ`
AWS::Events::EventBusPolicy (p. 896)	Event bus policy ID	`EventBusPolicy-1aBCdeFGh2J3`
AWS::Events::Rule (p. 882)	Event rule ID	`mystack-ScheduledRule-ABCDEFGHIJK`
AWS::GameLift::Alias (p. 1572)	Alias ID	`myalias-a01234b56-7890-1de2-f345-g67h8i901j2k`
AWS::GameLift::Build (p. 1575)	Build ID	`mybuild-a01234b56-7890-1de2-f345-g67h8i901j2k`
AWS::GameLift::Fleet (p. 1578)	Fleet ID	`myfleet-a01234b56-7890-1de2-f345-g67h8i901j2k`
AWS::Glue::Classifier (p. 1584)	Name	`abc123`
AWS::Glue::Connection (p. 1588)	`ConnectionInput` name	`abc123`
AWS::Glue::Crawler (p. 1593)	Name	`abc123`
AWS::Glue::Database (p. 1603)	`DatabaseInput` name	`abc123`

Resource Type	Reference Value	Example Return Value
AWS::Glue::Job (p. 1606)	Name	abc123
AWS::Glue::Table (p. 1621)	TableInput name	abc123
AWS::Glue::Trigger (p. 1632)	Name	abc123
AWS::GuardDuty::Detector (p. 1640)	Detector ID	12abc34d567e8fa901bc2d34e56789f0
AWS::GuardDuty::IPSet (p. 1645)	IPSet ID	0cb0141ab9fbde177613ab9436212e90
AWS::GuardDuty::Master (p. 1649)	Master ID	012345678901
AWS::GuardDuty::Member (p. 1654)	Member ID	012345678901
AWS::GuardDuty::ThreatIntelSet (p. 1659)	ThreatIntel Set ID	12a34567890bc1de2345f67ab8901234
AWS::IAM::AccessKey (p. 1657)	AccessKeyId	AKIAIOSFODNN7EXAMPLE
AWS::IAM::Group (p. 1658)	Group name	mystack-mygroup-1DZETITOWEKVO
AWS::IAM::ManagedPolicy (p. 1663)	Policy ARN	arn:aws:iam::123456789012:policy/teststack-CreateTestDBPolicy-16M23YE3CS700
AWS::IAM::Role (p. 1670)	Name	MyRole
AWS::IAM::User (p. 1678)	User name	mystack-myuser-1CCXAFG2H2U4D
AWS::IoT::Certificate (p. 1686)	Certificate ID	a1234567b89c012d3e4fg567hij8k9l01mno1p
AWS::IoT::Policy (p. 1691)	Policy name	MyPolicyName
AWS::IoT::Thing (p. 1694)	Thing name	MyStack-MyThing-AB1CDEFGHIJK
AWS::IoT::TopicRule (p. 1698)	Topic rule name	MyStackMyTopicRule12ABC3D456EFG
AWS::IoT1Click::Placement (p. 1720)	The placement name (associated with a project).	region3
AWS::IoT1Click::Project (p. 1723)	The project ARN.	arn:aws:iot1click:us-west-2:0123456789012:projects/seattle-region
AWS::IoT1Click::Device (p. 1718)	The device ARN.	arn:aws:iot1click:us-west-2:123456789012:devices/G030PX0312744DWM
AWS::Kinesis::Stream (p. 1727)	Name	mystack-mystream-1NAOH4L1RIQ7I
AWS::KinesisFirehose::DeliveryStream (p. 1730)	Delivery stream name	mystack-deliverystream-1ABCD2EF3GHIJ
AWS::KMS::Alias (p. 1786)	Alias name	alias/myAlias
AWS::KMS::Key (p. 1788)	Key ID	123ab456-a4c2-44cb-95fd-b781f32fbb37

Resource Type	Reference Value	Example Return Value
AWS::Lambda::Alias (p. 1795)	Amazon Resource Name of the AWS Lambda alias	arn:aws:lambda:us-west-2:123456789012:function:helloworl
AWS::Lambda::EventSourceMapping (p. 1793)	Name	MyStack-lambdaeventsourcemapping-CU6107MRVLR7
AWS::Lambda::Function (p. 1800)	Name	MyStack-AMILookUp-NT5EUXTNTXXD
AWS::Lambda::Version (p. 1816)	Amazon Resource Name of the AWS Lambda version	arn:aws:lambda:us-west-2:123456789012:function:helloworl
AWS::Logs::Destination (p. 899)	Destination name	TestDestination
AWS::Logs::LogGroup (p. 903)	Name	mystack-myLogGroup-1341JS4M96031
AWS::Logs::LogStream (p. 904)	Log stream name	MyAppLogStream
AWS::OpsWorks::App (p. 1917)	AWS OpsWorks Application ID	4fee5b96-0d10-4af1-bcc5-25f92e3c6acf
AWS::OpsWorks::Instance (p. 1919)	AWS OpsWorks Instance ID	aa2e9ae2-2b4b-491c-aeb6-8bf3ce9400fe
AWS::OpsWorks::Layer (p. 1935)	AWS OpsWorks Layer ID	730b238b-f7c4-461d-b7c0-3feb7ef1152a
AWS::OpsWorks::Stack (p. 1966)	AWS OpsWorks Stack ID	5c9f04e8-370e-4bd3-ae09-a4bbcc2998bb
AWS::OpsWorks::UserProfile (p. 1982)	IAM user Amazon Resource Name	arn:aws:iam::123456789012:user/opsworksuser
AWS::OpsWorks::Volume (p. 1985)	AWS OpsWorks Volume ID	1ab23cd4-92ff-4501-b37c-example
AWS::RDS::DBCluster (p. 1985)	Cluster name	test-rdscluster-pdedtss0mfqr
AWS::RDS::DBClusterParameterGroup (p. 1996)	Parameter group name	test-dbparamgroup-4l8qqx46vjby
AWS::RDS::DBInstance (p. 1998)	Name	mystack-mydb-ea5ugmfvuaxg
AWS::RDS::DBSecurityGroup (p. 1918)	Name	mystack-mydbsecuritygroup-1k5u5dxjb0nxs
AWS::RDS::DBSubnetGroup (p. 1924)	DB subnet group name	mystack-mydbsubnetgroup-1k5u5dxjb0nxs
AWS::RDS::OptionGroup (p. 1929)	Name	mystack-myoptiongroup-1qmfawfea4vmz
AWS::Redshift::Cluster (p. 1935)	Name	mystack-myredshiftcluster-ranmiv3f0mad
AWS::Redshift::ClusterParameterGroup (p. 1944)	Name	mysta-mypar-1AJYM1FL3WQBW

Resource Type	Reference Value	Example Return Value
AWS::Redshift::ClusterSecurityGroup (p. 1947)	Name	`mystack-myredshiftclustersecuritygroup-bjy2afmhy3ee`
AWS::Redshift::ClusterSubnetGroup (p. 1951)	Name	`mystack-myredshiftclustersubnetgroup-aq6rsdq8rp71`
AWS::Route53::HealthCheck (p. 1953)	Amazon Route 53 health check ID	`e0a123b4-4dba-4650-935e-example`
AWS::Route53::HostedZone (p. 1960)	Hosted zone ID	`Z23ABC4XYZL05B`
AWS::S3::Bucket (p. 1981)	Name	`mystack-mys3bucket-1hbsmonr9mytq`
AWS::SES::ReciptRule (p. 2102)	Name	`my-receipt-rule`
AWS::SES::ReciptRuleSet (p. 2118)	Name	`my-receipt-rule-set`
AWS::SDB::Domain (p. 2123)	Name	`mystack-mysdbdomain-IVNAOZTDFVXL`
AWS::SNS::Topic (p. 2128)	Topic ARN	`arn:aws:sns:us-east-2:123456789012:mystack-mytopic-NZJ5JSMVGFIE`
AWS::SQS::Queue (p. 2133)	Queue URL	`https://sqs.us-east-2.amazonaws.com/803981987763/aa4-MyQueue-Z5NOSZO2PZE9`
AWS::SSM::Document (p. 2150)	SSM document name	`ssm-myinstanceconfig-ABCNPH3XCAO6`
AWS::SSM::MaintenanceWindow (p. 2156)	Maintenance window ID	`mw-abcde1234567890yz`
AWS::SSM::MaintenanceWindowTarget (p. 2159)	Maintenance window target ID	`12a345b6-bbb7-4bb6-90b0-8c9577a2d2b9`
AWS::SSM::MaintenanceWindowTask (p. 2161)	Maintenance window task ID	`12a345b6-bbb7-4bb6-90b0-8c9577a2d2b9`
AWS::SSM::PatchBaseline (p. 2177)	Patch baseline ID	`pb-abcde1234567890yz` The ID of the default patch baseline provided by AWS is an ARN—for example `arn:aws:ssm:us-west-2:123456789012:patchbaseline/abcde1234567890yz`.
AWS::StepFunctions::Activity (p. 2213)	Amazon Resource Name (ARN) of the AWS Step Functions activity	`arn:aws:states:us-east-1:111122223333:activity:myActivit`
AWS::StepFunctions::StateMachine (p. 2245)	ARN of the created Step Functions state machine	`arn:aws:states:us-east-1:111122223333:stateMachine:MySta ABCDEFGHIJ1K`

Resource Type	Reference Value	Example Return Value
AWS::WAF::ByteMatchSet (p. 2188)	Byte match ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAF::IPSet (p. 2198)	IP set ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAF::Rule (p. 2197)	Rule ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAF::SizeConstraintSet (p. 2208)	Size constraint set ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAF::SqlInjectionMatchSet (p. 2205)	SQL match set ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAF::WebACL (p. 2209)	Web ACL ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAF::XssMatchSet (p. 2215)	XSS match set ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAFRegional::ByteMatchSet (p. 2220)	Byte match ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAFRegional::IPSet (p. 2225)	IP set ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAFRegional::Rule (p. 2229)	Rule ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAFRegional::SizeConstraintSet (p. 2232)	Size constraint set ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAFRegional::SqlInjectionMatchSet (p. 2237)	SQL match set ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAFRegional::WebACL (p. 2241)	Web ACL ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WAFRegional::XssMatchSet (p. 2248)	XSS match set ID	`aabc123a-fb4f-4fc6-becb-2b00831cadcf`
AWS::WorkSpaces::Workspace (p. 2253)	Workspace ID	`ws-cdd1gggh7`
Pseudo Parameter (p. 2352)	AWS::AccountId	`123456789012`
Pseudo Parameter (p. 2352)	AWS::NotificationARNs	`[arn:aws:sns:us-east-1:123456789012:MyTopic]`
Pseudo Parameter (p. 2352)	AWS::NoValue	Does not return a value.
Pseudo Parameter (p. 2352)	AWS::Partition	`aws`
Pseudo Parameter (p. 2352)	AWS::Region	`us-east-2`

Resource Type	Reference Value	Example Return Value
Pseudo Parameter (p. 2352)	AWS::StackId	`arn:aws:cloudformation:us-east-1:123456789012:stack/MyStack/1c2fa620-982a-11e3-aff7-50e2416294e0`
Pseudo Parameter (p. 2352)	AWS::StackName	`MyStack`

Pseudo Parameters Reference

Pseudo parameters are parameters that are predefined by AWS CloudFormation. You do not declare them in your template. Use them the same way as you would a parameter, as the argument for the `Ref` function.

Example

The following snippet assigns the value of the `AWS::Region` pseudo parameter to an output value:

JSON

```
"Outputs" : {
   "MyStacksRegion" : { "Value" : { "Ref" : "AWS::Region" } }
}
```

YAML

```
Outputs:
  MyStacksRegion:
    Value: !Ref "AWS::Region"
```

AWS::AccountId

Returns the AWS account ID of the account in which the stack is being created, such as `123456789012`.

AWS::NotificationARNs

Returns the list of notification Amazon Resource Names (ARNs) for the current stack.

To get a single ARN from the list, use Fn::Select (p. 2332).

JSON

```
"myASGrpOne" : {
   "Type" : "AWS::AutoScaling::AutoScalingGroup",
   "Version" : "2009-05-15",
   "Properties" : {
      "AvailabilityZones" : [ "us-east-1a" ],
      "LaunchConfigurationName" : { "Ref" : "MyLaunchConfiguration" },
      "MinSize" : "0",
      "MaxSize" : "0",
```

```
      "NotificationConfigurations" : [{
         "TopicARN" : { "Fn::Select" : [ "0", { "Ref" : "AWS::NotificationARNs" } ] },
         "NotificationTypes" : [ "autoscaling:EC2_INSTANCE_LAUNCH",
 "autoscaling:EC2_INSTANCE_LAUNCH_ERROR" ]
      }]
   }
}
```

YAML

```
myASGrpOne:

        Fn::Select:
        - '0'
        - Ref: AWS::NotificationARNs
      NotificationTypes:
      - autoscaling:EC2_INSTANCE_LAUNCH
      - autoscaling:EC2_INSTANCE_LAUNCH_ERROR
```

AWS::NoValue

Removes the corresponding resource property when specified as a return value in the `Fn::If` intrinsic function.

For example, you can use the `AWS::NoValue` parameter when you want to use a snapshot for an Amazon RDS DB instance only if a snapshot ID is provided. If the `UseDBSnapshot` condition evaluates to true, AWS CloudFormation uses the `DBSnapshotName` parameter value for the `DBSnapshotIdentifier` property. If the condition evaluates to false, AWS CloudFormation removes the `DBSnapshotIdentifier` property.

JSON

```
"MyDB" : {
  "Type" : "AWS::RDS::DBInstance",
  "Properties" : {
    "AllocatedStorage" : "5",
    "DBInstanceClass" : "db.m1.small",
    "Engine" : "MySQL",
    "EngineVersion" : "5.5",
    "MasterUsername" : { "Ref" : "DBUser" },
    "MasterUserPassword" : { "Ref" : "DBPassword" },
    "DBParameterGroupName" : { "Ref" : "MyRDSParamGroup" },
    "DBSnapshotIdentifier" : {
      "Fn::If" : [
        "UseDBSnapshot",
        {"Ref" : "DBSnapshotName"},
        {"Ref" : "AWS::NoValue"}
      ]
    }
  }
```

```
}
```

YAML

```
MyDB:
  Type: AWS::RDS::DBInstance
  Properties:
    AllocatedStorage: '5'
    DBInstanceClass: db.m1.small
    Engine: MySQL
    EngineVersion: '5.5'
    MasterUsername:
      Ref: DBUser
    MasterUserPassword:
      Ref: DBPassword
    DBParameterGroupName:
      Ref: MyRDSParamGroup
    DBSnapshotIdentifier:
      Fn::If:
      - UseDBSnapshot
      - Ref: DBSnapshotName
      - Ref: AWS::NoValue
```

AWS::Partition

Returns the partition that the resource is in. For standard AWS regions, the partition is `aws`. For resources in other partitions, the partition is `aws-`*`partitionname`*. For example, the partition for resources in the China (Beijing and Ningxia) region is `aws-cn` and the partition for resources in the AWS GovCloud (US) region is `aws-us-gov`.

AWS::Region

Returns a string representing the AWS Region in which the encompassing resource is being created, such as `us-west-2`.

AWS::StackId

Returns the ID of the stack as specified with the `aws cloudformation create-stack` command, such as `arn:aws:cloudformation:us-west-2:123456789012:stack/teststack/51af3dc0-da77-11e4-872e-1234567db123`.

AWS::StackName

Returns the name of the stack as specified with the `aws cloudformation create-stack` command, such as `teststack`.

AWS::URLSuffix

Returns the suffix for a domain. The suffix is typically `amazonaws.com`, but might differ by region. For example, the suffix for the China (Beijing) region is `amazonaws.com.cn`.

CloudFormation Helper Scripts Reference

AWS CloudFormation provides the following Python helper scripts that you can use to install software and start services on an Amazon EC2 instance that you create as part of your stack:

- cfn-init (p. 2358): Use to retrieve and interpret resource metadata, install packages, create files, and start services.
- cfn-signal (p. 2361): Use to signal with a CreationPolicy or WaitCondition, so you can synchronize other resources in the stack when the prerequisite resource or application is ready.
- cfn-get-metadata (p. 2365): Use to retrieve metadata for a resource or path to a specific key.
- cfn-hup (p. 2367): Use to check for updates to metadata and execute custom hooks when changes are detected.

You call the scripts directly from your template. The scripts work in conjunction with resource metadata that's defined in the same template. The scripts run on the Amazon EC2 instance during the stack creation process.

> **Note**
> The scripts are not executed by default. You must include calls in your template to execute specific helper scripts.

Amazon Linux AMI Images

The AWS CloudFormation helper scripts are preinstalled on Amazon Linux AMI images.

- On the latest Amazon Linux AMI version, the scripts are installed in `/opt/aws/bin`.
- On previous Amazon Linux AMI versions, the aws-cfn-bootstrap package that contains the scripts is located in the Yum repository.

Downloading Packages for Other Platforms

For Linux/Unix distributions other than Amazon Linux AMI images and for Microsoft Windows (2008 or later), you can download the aws-cfn-bootstrap package.

File Format	Download URL
RPM	https://s3.amazonaws.com/cloudformation-examples/aws-cfn-bootstrap-latest.amzn1.noarch.rpm Source files: https://s3.amazonaws.com/cloudformation-examples/aws-cfn-bootstrap-latest.src.rpm
TAR.GZ	https://s3.amazonaws.com/cloudformation-examples/aws-cfn-

File Format	Download URL
	bootstrap-latest.tar.gz Uses the Python easy-install tools. To complete the installation for Ubuntu, you must create a symlink: `ln -s /root/aws-cfn-bootstrap-latest/init/ubuntu/cfn-hup /etc/init.d/cfn-hup`
ZIP	https://s3.amazonaws.com/cloudformation-examples/aws-cfn-bootstrap-latest.zip
MSI	32-bit Windows: https://s3.amazonaws.com/cloudformation-examples/aws-cfn-bootstrap-latest.msi 64-bit Windows: https://s3.amazonaws.com/cloudformation-examples/aws-cfn-bootstrap-win64-latest.msi

Permissions for helper scripts

By default, helper scripts do not require credentials, so you do not need to use the `--access-key`, `--secret-key`, `--role`, or `--credential-file` options. However, if no credentials are specified, AWS CloudFormation checks for stack membership and limits the scope of the call to the stack that the instance belongs to.

If you choose to specify an option, we recommend that you specify only one of the following:

- `--role`
- `--credential-file`
- `--access-key` together with `--secret-key`

If you do specify an option, keep in mind which permissions the various helper scripts require:

- `cfn-signal` requires `cloudformation:SignalResource`
- All other helper scripts require `cloudformation:DescribeStackResource`

For more information on using AWS CloudFormation-specific actions and condition context keys in IAM policies, see Controlling Access with AWS Identity and Access Management (p. 9).

Using the Latest Version

The helper scripts are updated periodically. If you use the helper scripts, ensure that your launched instances are using the latest version of the scripts:

- Include the following command in the `UserData` property of your template before you call the scripts. This command ensures that you get the latest version:

  ```
  yum install -y aws-cfn-bootstrap
  ```
- If you don't include the `yum install` command and you use the `cfn-init`, `cfn-signal`, or `cfn-get-metadata` scripts, then you'll need to manually update the scripts in each Amazon EC2 Linux instance using this command:

  ```
  sudo yum install -y aws-cfn-bootstrap
  ```
- If you don't include the `yum install` command and you use the `cfn-hup` script, then you'll need to manually update the script in each Amazon EC2 Linux instance using these commands:

  ```
  sudo yum install -y aws-cfn-bootstrap

  sudo /sbin/service cfn-hup restart
  ```
- If you use the source code for the scripts to work with another version of Linux or a different platform, and you have created your own certificate trust store, you'll also need to keep the trust store updated.

For the version history of the aws-cfn-bootstrap package, see Release History for AWS CloudFormation Helper Scripts (p. 2492).

Topics

- cfn-init (p. 2358)
- cfn-signal (p. 2361)
- cfn-get-metadata (p. 2365)
- cfn-hup (p. 2367)

cfn-init

Description

The cfn-init helper script reads template metadata from the AWS::CloudFormation::Init key and acts accordingly to:

- Fetch and parse metadata from AWS CloudFormation
- Install packages
- Write files to disk
- Enable/disable and start/stop services

> **Note**
> If you use cfn-init to update an existing file, it creates a backup copy of the original file in the same directory with a .bak extension. For example, if you update `/path/to/file_name`, the action produces two files: `/path/to/file_name.bak` contains the original file's contents and `/path/to/file_name` contains the updated contents.

For information about the template metadata, see AWS::CloudFormation::Init (p. 803).

> **Note**
> cfn-init does not require credentials, so you do not need to use the `--access-key`, `--secret-key`, `--role`, or `--credential-file` options. However, if no credentials are specified, AWS CloudFormation checks for stack membership and limits the scope of the call to the stack that the instance belongs to.

Syntax

```
cfn-init --stack|-s stack.name.or.id \
         --resource|-r logical.resource.id \
         --region region
         --access-key access.key \
         --secret-key secret.key \
         --role rolename\
         --credential-file|-f credential.file \
         --configsets|-c config.sets \
         --url|-u service.url \
         --http-proxy HTTP.proxy \
         --https-proxy HTTPS.proxy \
         --verbose|-v
```

Options

Name	Description	Required
`-s, --stack`	Name of the Stack. *Type*: String *Default*: None *Example*: `-s { "Ref" : "AWS::StackName" },`	Yes
`-r, --resource`	The logical resource ID of the resource that contains the metadata.	Yes

Name	Description	Required
	Type: String *Example*: `-r WebServerHost`	
`--region`	The AWS CloudFormation regional endpoint to use. *Type*: String *Default*: `us-east-1` *Example*: `--region ", { "Ref" : "AWS::Region" },`	No
`--access-key`	AWS access key for an account with permission to call DescribeStackResource on AWS CloudFormation. The credential file parameter supersedes this parameter. *Type*: String	No
`--secret-key`	AWS secret access key that corresponds to the specified AWS access key. *Type*: String	No
`--role`	The name of an IAM role that is associated with the instance. *Type*: String Condition: The credential file parameter supersedes this parameter.	No
`-f, --credential-file`	A file that contains both a secret access key and an access key. The credential file parameter supersedes the --role, --access-key, and --secret-key parameters. *Type*: String	No
`-c, --configsets`	A comma-separated list of configsets to run (in order). *Type*: String *Default*: `default`	No
`-u, --url`	The AWS CloudFormation endpoint to use. *Type*: String	No
`--http-proxy`	An HTTP proxy (non-SSL). Use the following format: `http://user:password@host:port` *Type*: String	No
`--https-proxy`	An HTTPS proxy. Use the following format: `https://user:password@host:port` *Type*: String	No

Name	Description	Required
`-v`	Verbose output. This is useful for debugging cases where cfn-init is failing to initialize. **Note** To debug initialization events, you should turn DisableRollback on. You can do this by using the AWS CloudFormation console, selecting *Show Advanced Options*, and then setting "Rollback on failure" to "No". You can then SSH into the console and read the logs at /var/log/cfn-init.log.	No

Example

Amazon Linux Example

The following snippet shows the `UserData` property of an EC2 instance, which runs the `InstallAndRun` configset that is associated with the `WebServerInstance` resource.

For a complete example template, see Deploying Applications on Amazon EC2 with AWS CloudFormation (p. 262).

JSON

```
"UserData" : { "Fn::Base64" :
  { "Fn::Join" : ["", [
     "#!/bin/bash -xe\n",
     "# Install the files and packages from the metadata\n",
     "/opt/aws/bin/cfn-init -v ",
     "         --stack ", { "Ref" : "AWS::StackName" },
     "         --resource WebServerInstance ",
     "         --configsets InstallAndRun ",
     "         --region ", { "Ref" : "AWS::Region" }, "\n"
  ]]}
}
```

YAML

```
UserData: !Base64
  'Fn::Join':
    - ''
    - - |
        #!/bin/bash -xe
      - |
        # Install the files and packages from the metadata
      - '/opt/aws/bin/cfn-init -v '
      - '         --stack '
      - !Ref 'AWS::StackName'
      - '         --resource WebServerInstance '
      - '         --configsets InstallAndRun '
      - '         --region '
      - !Ref 'AWS::Region'
      - |+
```

cfn-signal

Description

The cfn-signal helper script signals AWS CloudFormation to indicate whether Amazon EC2 instances have been successfully created or updated. If you install and configure software applications on instances, you can signal AWS CloudFormation when those software applications are ready.

You use the cfn-signal script in conjunction with a CreationPolicy (p. 2270) or an Auto Scaling group with a `WaitOnResourceSignals` (p. 2281) update policy. When AWS CloudFormation creates or updates resources with those policies, it suspends work on the stack until the resource receives the requisite number of signals or until the timeout period is exceeded. For each valid signal that AWS CloudFormation receives, AWS CloudFormation publishes the signals to the stack events so that you track each signal. For a walkthrough that uses a creation policy and cfn-signal, see Deploying Applications on Amazon EC2 with AWS CloudFormation (p. 262).

> **Note**
> cfn-signal does not require credentials, so you do not need to use the `--access-key`, `--secret-key`, `--role`, or `--credential-file` options. However, if no credentials are specified, AWS CloudFormation checks for stack membership and limits the scope of the call to the stack that the instance belongs to.

Syntax for Resource Signaling (Recommended)

If you want to signal AWS CloudFormation resources, use the following syntax.

```
cfn-signal --success|-s signal.to.send \
        --access-key access.key \
        --credential-file|-f credential.file \
        --exit-code|-e exit.code \
        --http-proxy HTTP.proxy \
        --https-proxy HTTPS.proxy \
        --id|-i unique.id \
        --region AWS.region \
        --resource resource.logical.ID \
        --role IAM.role.name \
        --secret-key secret.key \
        --stack stack.name.or.stack.ID \
        --url AWS CloudFormation.endpoint
```

Syntax for Use with Wait Condition Handle

If you want to signal a wait condition handle, use the following syntax.

```
cfn-signal --success|-s signal.to.send \
        --reason|-r resource.status.reason \
        --data|-d data \
        --id|-i unique.id \
        --exit-code|-e exit.code \
        waitconditionhandle.url
```

Options

The options that you can use depend on whether you're signaling a creation policy or a wait condition handle. Some options that apply to a creation policy might not apply to a wait condition handle.

Name	Description	Required
`--access-key` (resource signaling only)	AWS access key for an account with permission to call the AWS CloudFormation `SignalResource` API. The credential file parameter supersedes this parameter. *Type*: String	No
`-d, --data` (wait condition handle only)	Data to send back with the `waitConditionHandle`. Defaults to blank. *Type*: String *Default*: blank	No
`-e, --exit-code`	The error code from a process that can be used to determine success or failure. If specified, the `--success` option is ignored. *Type*: String *Examples*: `-e $?` (for Linux), `-e %ERRORLEVEL%` (for Windows cmd.exe), and `-e $lastexitcode` (for Windows PowerShell).	No
`-f, --credential-file` (resource signaling only)	A file that contains both a secret access key and an access key. The credential file parameter supersedes the --role, --access-key, and --secret-key parameters. *Type*: String	No
`--http-proxy`	An HTTP proxy (non-SSL). Use the following format: `http://user:password@host:port` *Type*: String	No
`--https-proxy`	An HTTPS proxy. Use the following format: `https://user:password@host:port` *Type*: String	No
`-i, --id`	The unique ID to send. *Type*: String *Default*: The ID of the Amazon EC2 instance. If the ID cannot be resolved, the machine's Fully Qualified Domain Name (FQDN) is returned.	No
`-r, --reason` (wait condition handle only)	A status reason for the resource event (currently only used on failure) - defaults to 'Configuration failed' if success is false. *Type*: String	No
`--region` (resource signaling only)	The AWS CloudFormation regional endpoint to use. *Type*: String	No

Name	Description	Required
	Default: `us-east-1`	
`--resource` (resource signaling only)	The logical ID (p. 197) of the resource that contains the creations policy you want to signal. *Type*: String	Yes
`--role` (resource signaling only)	The name of an IAM role that is associated with the instance. *Type*: String Condition: The credential file parameter supersedes this parameter.	No
`-s, --success`	if true, signal SUCCESS, else FAILURE. *Type*: Boolean *Default*: `true`	No
`--secret-key` (resource signaling only)	AWS secret access key that corresponds to the specified AWS access key. *Type*: String	No
`--stack` (resource signaling only)	The stack name or stack ID that contains the resource you want to signal. *Type*: String	Yes
`-u, --url` (resource signaling only)	The AWS CloudFormation endpoint to use. *Type*: String	No
`waitconditionhandle.url` (wait condition handle only)	A presigned URL that you can use to signal success or failure to an associated `WaitCondition` *Type*: String	Yes

Example

Amazon Linux Example

A common usage pattern is to use cfn-init and cfn-signal together. The cfn-signal call uses the return status of the call to cfn-init (using the $? shell construct). If the application fails to install, the instance will fail to create and the stack will rollback. For Windows stacks, see Bootstrapping AWS CloudFormation Windows Stacks (p. 159).

            - '         --resource MyInstance '
            - '         --region '
            - !Ref 'AWS::Region'
            - |+

    CreationPolicy:
      ResourceSignal:
        Timeout: PT5M
```

Examples

Several AWS CloudFormation sample templates use cfn-signal, including the following templates.

- LAMP: Single EC2 Instance with local MySQL database
- WordPress: Single EC2 Instance with local MySQL database

cfn-get-metadata

Description

You can use the cfn-get-metadata helper script to fetch a metadata block from AWS CloudFormation and print it to standard out. You can also print a sub-tree of the metadata block if you specify a key. However, only top-level keys are supported.

Note
cfn-get-metadata does not require credentials, so you do not need to use the `--access-key`, `--secret-key`, `--role`, or `--credential-file` options. However, if no credentials are specified, AWS CloudFormation checks for stack membership and limits the scope of the call to the stack that the instance belongs to.

Syntax

```
cfn-get-metadata --access-key access.key \
                 --secret-key secret.key \
                 --credential-file|f credential.file \
                 --key|k key \
                 --stack|-s stack.name.or.id \
                 --resource|-r logical.resource.id \
                 --role IAM.role.name \
                 --url|-u service.url \
                 --region region
```

Options

Name	Description	Required
`-k, --key`	For a key-value pair, returns the name of the key for the value that you specified. *Type*: String *Example*: For `{ "SampleKey1" : "Key1", "SampleKey2" : "Key2" }`, `cfn-get-metadata -k Key2` returns `SampleKey2`.	No
`-s, --stack`	Name of the Stack. *Type*: String *Default*: None *Example*: `-s { "Ref" : "AWS::StackName" },`	Yes
`-r, --resource`	The logical resource ID of the resource that contains the metadata. *Type*: String *Example*: `-r WebServerHost`	Yes
`--role` (resource signaling only)	The name of an IAM role that is associated with the instance. *Type*: String Condition: The credential file parameter supersedes this parameter.	No
`--region`	The region to derive the AWS CloudFormation URL from. *Type*: String	No

Name	Description	Required
	Default: None *Example*: `--region ", { "Ref" : "AWS::Region" },`	
`--access-key`	AWS Access Key for an account with permission to call DescribeStackResource on AWS CloudFormation. *Type*: String Condition: The credential file parameter supersedes this parameter.	Conditional
`--secret-key`	AWS Secret Key that corresponds to the specified AWS Access Key. *Type*: String Condition: The credential file parameter supersedes this parameter.	Conditional
`-f, --credential-file`	A file that contains both a secret key and an access key. *Type*: String Condition: The credential file parameter supersedes the --access-key and --secret-key parameters.	Conditional

cfn-hup

Description

The cfn-hup helper is a daemon that detects changes in resource metadata and runs user-specified actions when a change is detected. This allows you to make configuration updates on your running Amazon EC2 instances through the UpdateStack API action.

Syntax

```
cfn-hup --config|-c config.dir \
        --no-daemon \
        --verbose|-v
```

Options

Name	Description	Required
`--config|-c config.dir`	Specifies the path that the cfn-hup script looks for the `cfn-hup.conf` and the `hooks.d` directories. On Windows, the default path is *`system_drive`*`\cfn`. On Linux, the default path is `/etc/cfn`.	No
`--no-daemon`	Specify this option to run the cfn-hup script once and exit.	No

Name	Description	Required
`-v, --verbose`	Specify this option to use verbose mode.	No

cfn-hup.conf Configuration File

The cfn-hup.conf file stores the name of the stack and the AWS credentials that the cfn-hup daemon targets.

The cfn-hup.conf file uses the following format:

```
[main]
stack=<stack-name-or-id>
```

Name	Description	Required
`stack`	A stack name or ID. *Type*: String	Yes
`credential-file`	An owner-only credential file, in the same format used for the command line tools. *Type*: String *Condition*: The `role` parameter supersedes this parameter.	No
`role`	The name of an IAM role that is associated with the instance. *Type*: String	No
`region`	The name of the AWS region containing the stack. *Example*: `us-east-2`	No
`umask`	The umask used by the cfn-hup daemon. This value can be specified with or without a leading 0. In both cases, it is interpreted as an octal number (very similar to the Linux `umask` command). This parameter has no effect on Windows. *Type*: Octal integer between `0` and `0777` *Default*: `022`, version 1.4-22 and higher. The default value of `022` masks group and world write permissions, so files created by the cfn-hup daemon are not group or world writable by default. The default value for versions 1.4-21 and earlier is `0`, which masks nothing.	No
`interval`	The interval used to check for changes to the resource metadata in minutes *Type*: Number	No

Name	Description	Required
	Default: `15`	
`verbose`	Specifies whether to use verbose logging. *Type*: Boolean *Default*: `false`	No

hooks.conf Configuration File

The user actions that the cfn-hup daemon calls periodically are defined in the hooks.conf configuration file. The hooks.conf file uses the following *format*:

```
[hookname]
triggers=post.add or post.update or post.remove
path=Resources.<logicalResourceId> (.Metadata or .PhysicalResourceId)
(.<optionalMetadatapath>)
action=<arbitrary shell command>
runas=<runas user>
```

When the action is run, it is run in a copy of the current environment (that cfn-hup is in), with CFN_OLD_METADATA set to the previous value of path, and CFN_NEW_METADATA set to the current value.

The hooks configuration file is loaded at cfn-hup daemon startup only, so new hooks will require the daemon to be restarted. A cache of previous metadata values is stored at /var/lib/cfn-hup/data/metadata_db—you can delete this cache to force cfn-hup to run all post.add actions again.

Name	Description	Required
`hookname`	A unique name for this hook *Type*: String	Yes
`triggers`	A comma-delimited list of conditions to detect. *Valid values*: `post.add`, `post.update`, or `post.remove` *Example*: `post.add, post.update`	Yes
`path`	The path to the metadata object. Supports an arbitrarily deep path within the Metadata block. **Path format options** • Resources.*<LogicalResourceId>*—monitor the last updated time of the resource, triggering on any change to the resource. • Resources.*<LogicalResourceId>*.PhysicalResourceId—monitor the physical ID of the resource, triggering only when the associated resource identity changes (such as a new EC2 instance). • Resources.*<LogicalResourceId>*.Metadata(*.optional path*)—monitor the metadata of a resource for	Yes

Name	Description	Required
	changes (a metadata subpath may be specified to an arbitrarily deep level to monitor specific values).	
`action`	An arbitrary shell command that is run as given.	Yes
`runas`	A user to run the commands as. Cfn-hup uses the su command to switch to the user.	Yes

hooks.d Directory

To support composition of several applications deploying change notification hooks, cfn-hup supports a directory named hooks.d that is located in the hooks configuration directory. You can place one or more additional hooks configuration files in the hooks.d directory. The additional hooks files must use the same layout as the hooks.conf file.

The cfn-hup daemon parses and loads each file in this directory. If any hooks in the hooks.d directory have the same name as a hook in hooks.conf, the hooks will be merged (meaning hooks.d will overwrite hooks.conf for any values that both files specify).

Example

In the following template snippet, AWS CloudFormation triggers the `cfn-auto-reloader.conf` hooks file when you change the `AWS::CloudFormation::Init` resource that is associated with the `LaunchConfig` resource.

JSON

```
...
    "LaunchConfig": {
      "Type" : "AWS::AutoScaling::LaunchConfiguration",
      "Metadata" : {
        "QBVersion": {"Ref": "paramQBVersion"},
        "AWS::CloudFormation::Init" : {
...
              "/etc/cfn/hooks.d/cfn-auto-reloader.conf": {
                "content": { "Fn::Join": [ "", [
                  "[cfn-auto-reloader-hook]\n",
                  "triggers=post.update\n",
                  "path=Resources.LaunchConfig.Metadata.AWS::CloudFormation::Init\n",
                  "action=/opt/aws/bin/cfn-init -v ",
                          "         --stack ", { "Ref" : "AWS::StackName" },
                          "         --resource LaunchConfig ",
                          "         --configsets wordpress_install ",
                          "         --region ", { "Ref" : "AWS::Region" }, "\n",
                  "runas=root\n"
                ]]},
                "mode"  : "000400",
                "owner" : "root",
                "group" : "root"
              }
...
```

YAML

```
...
  LaunchConfig:
```

```
    Type: "AWS::AutoScaling::LaunchConfiguration"
    Metadata:
      QBVersion: !Ref paramQBVersion
      AWS::CloudFormation::Init:
...
            /etc/cfn/hooks.d/cfn-auto-reloader.conf:
              content: !Sub |
                [cfn-auto-reloader-hook]
                triggers=post.update
                path=Resources.LaunchConfig.Metadata.AWS::CloudFormation::Init
                action=/opt/aws/bin/cfn-init -v --stack ${AWS::StackName} --resource
 LaunchConfig --configsets wordpress_install --region ${AWS::Region}
                runas=root
              mode: "000400"
              owner: "root"
              group: "root"
...
```

Additional Example

For a sample template, see Deploying Applications on Amazon EC2 with AWS CloudFormation (p. 262).

Sample Templates

AWS CloudFormation sample templates demonstrate how you can create templates for various uses. For example, one sample template describes a load-balancing, auto scaling WordPress blog in an Amazon VPC. We recommend that you use these sample templates as a starting point for creating your own templates and not to launch production-level environments.

To view the sample templates, go to https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/cfn-sample-templates.html

> **Note**
> The AWS Quick Starts use AWS CloudFormation templates to automate software deployments, such as a Chef Server or MongoDB, on AWS. You can use these templates to learn how to deploy your own solution on AWS. For more information, see AWS Quick Start Reference Deployments.

Troubleshooting AWS CloudFormation

When you use AWS CloudFormation, you might encounter issues when you create, update, or delete AWS CloudFormation stacks. The following sections can help you troubleshoot some common issues that you might encounter.

For general questions about AWS CloudFormation, see the AWS CloudFormation FAQs. You can also search for answers and post questions in the AWS CloudFormation forums.

Topics

- Troubleshooting Guide (p. 2373)
- Troubleshooting Errors (p. 2373)
- Contacting Support (p. 2378)

Troubleshooting Guide

If AWS CloudFormation fails to create, update, or delete your stack, you can view error messages or logs to help you learn more about the issue. The following tasks describe general methods for troubleshooting a AWS CloudFormation issue. For information about specific errors and solutions, see the Troubleshooting Errors (p. 2373) section.

- Use the AWS CloudFormation console to view the status of your stack. In the console, you can view a list of stack events while your stack is being created, updated, or deleted. From this list, find the failure event and then view the status reason for that event. The status reason might contain an error message from AWS CloudFormation or from a particular service that can help you troubleshoot your problem. For more information about viewing stack events, see Viewing Stack Data and Resources (p. 101).
- For Amazon EC2 issues, view the cloud-init and cfn logs. These logs are published on the Amazon EC2 instance in the `/var/log/` directory. These logs capture processes and command outputs while AWS CloudFormation is setting up your instance. For Windows, view the EC2Configure service and cfn logs in `%ProgramFiles%\Amazon\EC2ConfigService` and `C:\cfn\log`.

  You can also configure your AWS CloudFormation template so that the logs are published to Amazon CloudWatch, which displays logs in the AWS Management Console so you don't have to connect to your Amazon EC2 instance. For more information, see View CloudFormation Logs in the Console in the Application Management Blog.

Troubleshooting Errors

When you come across the following errors with your AWS CloudFormation stack, you can use the following solutions to help you find the source of the problems and fix them.

Topics

- Delete Stack Fails (p. 2374)
- Dependency Error (p. 2374)

- Error Parsing Parameter When Passing a List (p. 2375)
- Insufficient IAM Permissions (p. 2375)
- Invalid Value or Unsupported Resource Property (p. 2375)
- Limit Exceeded (p. 2375)
- Nested Stacks are Stuck in UPDATE_COMPLETE_CLEANUP_IN_PROGRESS, UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS, or UPDATE_ROLLBACK_IN_PROGRESS (p. 2375)
- No Updates to Perform (p. 2376)
- Resource Failed to Stabilize During a Create, Update, or Delete Stack Operation (p. 2376)
- Security Group Does Not Exist in VPC (p. 2376)
- Update Rollback Failed (p. 2377)
- Wait Condition Didn't Receive the Required Number of Signals from an Amazon EC2 Instance (p. 2378)

Delete Stack Fails

To resolve this situation, try the following:

- Some resources must be empty before they can be deleted. For example, you must delete all objects in an Amazon S3 bucket or remove all instances in an Amazon EC2 security group before you can delete the bucket or security group.
- Ensure that you have the necessary IAM permissions to delete the resources in the stack. In addition to AWS CloudFormation permissions, you must be allowed to use the underlying services, such as Amazon S3 or Amazon EC2.
- When stacks are in the `DELETE_FAILED` state because AWS CloudFormation couldn't delete a resource, rerun the deletion with the `RetainResources` parameter and specify the resource that AWS CloudFormation can't delete. AWS CloudFormation deletes the stack without deleting the retained resource. Retaining resources is useful when you can't delete a resource, such as an S3 bucket that contains objects that you want to keep, but you still want to delete the stack.

  After you delete the stack, you can manually delete retained resources by using their associated AWS service.
- You cannot delete stacks that have termination protection enabled. If you attempt to delete a stack with termination protection enabled, the deletion fails and the stack--including its status--remains unchanged. Disable termination protection on the stack, then perform the delete operation again.

  This includes nested stacks (p. 157) whose root stacks have termination protection enabled. Disable termination protection on the root stack, then perform the delete operation again. It is strongly recommended that you do not delete nested stacks directly, but only delete them as part of deleting the root stack and all its resources.

  For more information, see Protecting a Stack From Being Deleted (p. 108).
- For all other issues, if you have AWS Premium Support, you can create a Technical Support case. See Contacting Support (p. 2378).

Dependency Error

To resolve a dependency error, add a `DependsOn` attribute to resources that depend on other resources in your template. In some cases, you must explicitly declare dependencies so that AWS CloudFormation can create or delete resources in the correct order. For example, if you create an Elastic IP and a VPC with an Internet gateway in the same stack, the Elastic IP must depend on the Internet gateway attachment. For additional information, see DependsOn Attribute (p. 2275).

Error Parsing Parameter When Passing a List

When you use the AWS Command Line Interface or AWS CloudFormation to pass in a list, add the escape character (\) before each comma. The following sample shows how you specify an input parameter when using the CLI.

```
ParameterKey=CIDR,ParameterValue='10.10.0.0/16\,10.10.0.0/24\,10.10.1.0/24'
```

Insufficient IAM Permissions

When you work with an AWS CloudFormation stack, you not only need permissions to use AWS CloudFormation, you must also have permission to use the underlying services that are described in your template. For example, if you're creating an Amazon S3 bucket or starting an Amazon EC2 instance, you need permissions to Amazon S3 or Amazon EC2. Review your IAM policy and verify that you have the necessary permissions before you work with AWS CloudFormation stacks. For more information see, Controlling Access with AWS Identity and Access Management (p. 9).

Invalid Value or Unsupported Resource Property

When you create or update an AWS CloudFormation stack, your stack can fail due to invalid input parameters, unsupported resource property names, or unsupported resource property values. For input parameters, verify that the resource exists. For example, when you specify an Amazon EC2 key pair or VPC ID, the resource must exist in your account and in the region in which you are creating or updating your stack. You can use AWS-specific parameter types (p. 171) to ensure that you use valid values.

For resource property names and values, update your template to use valid names and values. For a list of all the resources and their property names, see AWS Resource and Property Types Reference (p. 518).

Limit Exceeded

Verify that you didn't reach a resource limit. For example, the default number Amazon EC2 instances that you can launch is 20. If try to create more Amazon EC2 instances than your account limit, the instance creation fails and you receive the error `Status=start_failed`. To view the default AWS limits by service, see AWS Service Limits in the *AWS General Reference*.

For AWS CloudFormation limits and tweaking strategies, see AWS CloudFormation Limits (p. 21).

Also, during an update, if a resource is replaced, AWS CloudFormation creates new resource before it deletes the old one. This replacement might put your account over the resource limit, which would cause your update to fail. You can delete excess resources or request a limit increase.

Nested Stacks are Stuck in `UPDATE_COMPLETE_CLEANUP_IN_PROGRESS`, `UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS`, or `UPDATE_ROLLBACK_IN_PROGRESS`

A nested stack failed to roll back. Because of potential resource dependencies between nested stacks, AWS CloudFormation doesn't start cleaning up nested stack resources until all nested stacks have been updated or have rolled back. When a nested stack fails to roll back, AWS CloudFormation cancels all operations, regardless of the state that the other nested stacks are in. A nested stack that completed updating or rolling back but did not receive a signal from AWS CloudFormation to start cleaning up

because another nested failed to roll back is in an `UPDATE_COMPLETE_CLEANUP_IN_PROGRESS` or `UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS` state. A nested stack that failed to update but did not receive a signal to start rolling back is in an `UPDATE_ROLLBACK_IN_PROGRESS` state.

A nested stack might fail to roll back because of changes that were made outside of AWS CloudFormation, when the stack template doesn't accurately reflect the state of the stack. A nested stack might also fail if an Auto Scaling group in a nested stack had an insufficient resource signal timeout period when the group was created or updated.

To fix the stack, contact AWS customer support (p. 2378).

No Updates to Perform

To update an AWS CloudFormation stack, you must submit template or parameter value changes to AWS CloudFormation. However, AWS CloudFormation won't recognize some template changes as an update, such as changes to a deletion policy, update policy, condition declaration, or output declaration. If you need to make such changes without making any other change, you can add or modify a metadata (p. 2280) attribute for any of your resources.

For more information about modifying templates during an update, see Modifying a Stack Template (p. 121).

Resource Failed to Stabilize During a Create, Update, or Delete Stack Operation

A resource did not respond because the operation exceeded the AWS CloudFormation timeout period or an AWS service was interrupted. For service interruptions, check that the relevant AWS service is running, and then retry the stack operation.

If the AWS services have been running successfully, check if your stack contains one of the following resources:

- `AWS::AutoScaling::AutoScalingGroup` for create, update, and delete operations
- `AWS::CertificateManager::Certificate` for create operations
- `AWS::CloudFormation::Stack` for create, update, and delete operations
- `AWS::ElasticSearch::Domain` for update operations
- `AWS::RDS::DBCluster` for create and update operations
- `AWS::RDS::DBInstance` for create, update, and delete operations
- `AWS::Redshift::Cluster` for update operations

Operations for these resources might take longer than the default timeout period. The timeout period depends on the resource and credentials that you use. To extend the timeout period, specify a service role (p. 17) when you perform the stack operation. If you're already using a service role, or if your stack contains a resource that isn't listed, contact AWS customer support (p. 2378).

If your stack is in the `UPDATE_ROLLBACK_FAILED` state, see Update Rollback Failed (p. 2377).

Security Group Does Not Exist in VPC

Verify that the security group exists in the VPC that you specified. If the security group exists, ensure that you specify the security group ID and not the security group name. For example, the `AWS::EC2::SecurityGroupIngress` resource has a `SourceSecurityGroupName` and `SourceSecurityGroupId` properties. For VPC security groups, you must use the `SourceSecurityGroupId` property and specify the security group ID.

Update Rollback Failed

A dependent resource cannot return to its original state, causing the rollback to fail (`UPDATE_ROLLBACK_FAILED` state). For example, you might have a stack that is rolling back to an old database instance that was deleted outside of AWS CloudFormation. Because AWS CloudFormation doesn't know the database was deleted, it assumes that the database instance still exists and attempts to roll back to it, causing the update rollback to fail.

Depending on the cause of the failure, you can manually fix the error and continue the rollback. By continuing the rollback, you can return your stack to a working state (the `UPDATE_ROLLBACK_COMPLETE` state), and then try to update the stack again. The following list describes solutions to common errors that cause update rollback failures:

- Failed to receive the required number of signals

  Use the signal-resource command to manually send the required number of successful signals to the resource that is waiting for them, and then continue rolling back the update. For example, during an update rollback, instances in an Auto Scaling group might fail to signal success within the specified timeout duration. Manually send success signals to the Auto Scaling group. When you continue the update rollback, AWS CloudFormation sees your signals and proceeds with the rollback.
- Changes to a resource were made outside of AWS CloudFormation

  Manually sync resources so that they match the original stack's template, and then continue rolling back the update. For example, if you manually deleted a resource that AWS CloudFormation is attempting to roll back to, you must manually create that resource with the same name and properties it had in the original stack.
- Insufficient permissions

  Check that you have sufficient IAM permissions to modify resources, and then continue the update rollback. For example, your IAM policy might allow you to create an S3 bucket, but not modify the bucket. Add the modify actions to your policy.
- Invalid security token

  AWS CloudFormation requires a new set of credentials. No change is required. Continue rolling back the update, which refreshes the credentials.
- Limitation error

  Delete resources that you don't need or request a limit increase, and then continue rolling back the update. For example, if your account limit for the number of EC2 instances is 20 and the update rollback exceeds that limit, it will fail.
- Resource did not stabilize

  A resource did not respond because the operation might have exceeded the AWS CloudFormation timeout period or an AWS service might have been interrupted. No change is required. After the resource operation is complete or the AWS service is back in operation, continue rolling back the update.

To continue rolling back an update, you can use the AWS CloudFormation console or AWS command line interface (CLI). For more information, see Continue Rolling Back an Update (p. 152).

If none of these solutions work, you can skip the resources that AWS CloudFormation can't successfully roll back. For more information, see the `ResourcesToSkip` parameter for the ContinueUpdateRollback action in the *AWS CloudFormation API Reference*. AWS CloudFormation sets the status of the specified resources to `UPDATE_COMPLETE` and continues to roll back the stack. After the rollback is complete, the state of the skipped resources will be inconsistent with the state of the resources in the stack template.

Before you perform another stack update, you must modify the resources or update the stack to be consistent with each other. If you don't, subsequent stack updates might fail and make your stack unrecoverable.

Wait Condition Didn't Receive the Required Number of Signals from an Amazon EC2 Instance

To resolve this situation, try the following:

- Ensure that the AMI you're using has the AWS CloudFormation helper scripts installed. If the AMI doesn't include the helper scripts, you can also download them to your instance. For more information, see CloudFormation Helper Scripts Reference (p. 2354).
- Verify that the `cfn-signal` command was successfully run on the instance. You can view logs, such as `/var/log/cloud-init.log` or `/var/log/cfn-init.log`, to help you debug the instance launch. You can retrieve the logs by logging in to your instance, but you must disable rollback on failure (p. 97) or else AWS CloudFormation deletes the instance after your stack fails to create. You can also publish the logs to Amazon CloudWatch. For Windows, you can view cfn logs in `C:\cfn\log` and EC2Config service logs in `%ProgramFiles%\Amazon\EC2ConfigService`.
- Verify that the instance has a connection to the Internet. If the instance is in a VPC, the instance should be able to connect to the Internet through a NAT device if it's is in a private subnet or through an Internet gateway if it's in a public subnet. To test the instance's Internet connection, try to access a public web page, such as `http://aws.amazon.com`. For example, you can run the following command on the instance. It should return an HTTP 200 status code.

  ```
  curl -I https://aws.amazon.com
  ```

  For information about configuring a NAT device, see NAT in the *Amazon VPC User Guide*.

Contacting Support

If you have AWS Premium Support, you can create a technical support case at https://console.aws.amazon.com/support/home#/. Before you contact support, gather the following information:

- The ID of the stack. You can find the stack ID in the **Overview** tab of the AWS CloudFormation console. For more information, see Viewing Stack Data and Resources (p. 101).

  Important
  Do not make changes to the stack outside of AWS CloudFormation. Making changes to your stack outside of AWS CloudFormation might put your stack in an unrecoverable state.
- Any stack error messages. For information about viewing stack error messages, see the Troubleshooting Guide (p. 2373) section.
- For Amazon EC2 issues, gather the cloud-init and cfn logs. These logs are published on the Amazon EC2 instance in the `/var/log/` directory. These logs capture processes and command outputs while your instance is setting up. For Windows, gather the EC2Configure service and cfn logs in `%ProgramFiles%\Amazon\EC2ConfigService` and `C:\cfn\log`.

You can also search for answers and post questions in the AWS CloudFormation forums.

Release History

The following table describes important changes in each release of the AWS CloudFormation User Guide after May 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

update-history-change	update-history-description	update-history-date
Updated resource (p. 2379)	The following resource was updated: AWS::SSM:MaintenanceWindow AWS::SSM::MaintenanceWindow (p. 2156) Use the `StartDate` and `StartDate` property types to specivy when you want the Maintenance Window to become active or inactive. Use the `ScheduleTimezone` property type to specify the time zone to base scheduled Maintenance Window executions on, in Internet Assigned Numbers Authority (IANA) format.	November 1, 2018
New resources (p. 2379)	The following resources were added: AWS::AppStream::DirectoryConfig, AWS::AppStream::Fleet, AWS::AppStream::ImageBuilder, AWS::AppStream::Stack, AWS::AppStream::StackFleetAssociation, AWS::AppStream::StackUserAssociation, AWS::AppStream::User. AWS::AppStream::DirectoryConfig (p. 653) Use the `AWS::AppStream::DirectoryConfig` resource to describe the configuration information required to join Amazon AppStream 2.0 fleets and image builders to Microsoft Active Directory domains. AWS::AppStream::Fleet (p. 655) Use the `AWS::AppStream::Fleet` resource to create a fleet for Amazon AppStream 2.0. A fleet consists of	October 25, 2018

streaming instances that run a specified image.

AWS::AppStream::ImageBuilder (p. 660)

Use the `AWS::AppStream::ImageBuilder` resource to create an image builder for Amazon AppStream 2.0.

AWS::AppStream::Stack (p. 664)

Use the `AWS::AppStream::Stack` resource to create a stack to start streaming applications to Amazon AppStream 2.0 users.

AWS::AppStream::StackFleetAssociation (p. 669)

Use the `AWS::AppStream::StackFleetAssociation` resource to associate a fleet with a stack for Amazon AppStream 2.0.

AWS::AppStream::StackUserAssociation (p. 671)

Use the `AWS::AppStream::StackUserAssociation` resource to associate the specified stacks with the specified users for Amazon AppStream 2.0. Users in a user pool cannot be assigned to stacks with fleets that are joined to an Active Directory domain.

AWS::AppStream::User (p. 672)

Use the `AWS::AppStream::User` resource to create a new user in the user pool for Amazon AppStream 2.0.

Updated resources (p. 2379)	Updated the following resources: AWS::AmazonMQ::Broker, AWS::GuardDuty::Detector and AWS::SSM::PatchBaseline. AWS::AmazonMQ::Broker (p. 520) Amazon MQ now supports engine versions 5.15.6 and 5.15.0. Property changes include: • The `EngineVersion` property now requires some interruptions upon update. • The `AutoMinorVersionUpgrade` property now requires no interruption upon update. AWS::GuardDuty::Detector (p. 1641) Use the `FindingPublishingFrequency` property to specify the frequency of notifications sent about the subsequent finding occurrences. AWS::SSM::PatchBaseline (p. 2177) Use the `PatchSource` property type to provide information about the patches to use to update target instances.	October 18, 2018
New resource (p. 2379)	Added the AWS::Events::EventBusPolicy resource. AWS::Events::EventBusPolicy (p. 896) Use the `AWS::Events::EventBusPolicy` resource to grant permission to other AWS accounts that send events to your account.	October 18, 2018

UseOnlineResharding update policy now available. (p. 2379)	To modify a replication group's shards by adding or removing shards, rather than replacing the entire `AWS::ElastiCache::ReplicationGroup` resource, use the `UseOnlineResharding` update policy. For more information, see UseOnlineResharding Policy (p. 2286).	September 20, 2018

Updated resources (p. 2379)	The following resources have been updated: AWS::ApiGateway::Deployment, AWS::ApiGateway::Method, AWS::ApiGateway::Stage, AWS::ApiGateway::UsagePlan, AWS::CodeBuild::Project, AWS::CodeDeploy::DeploymentGroup, AWS::EC2::FlowLog, AWS::EC2::SpotFleet, AWS::EC2::VPCEndpoint, AWS::ECS::Service, AWS::ECS::TaskDefinition, and AWS::RDS::DBCluster. AWS::ApiGateway::Deployment (p. 547) Use the `DeploymentCanarySettings` property to specify settings for the canary deployment. In the StageDescription (p. 554) property type: • Use the `AccessLogSetting` property to specify settings for logging access in this stage. • Use the `CanarySetting` property to specify settings for the canary deployment in this stage. AWS::ApiGateway::Method (p. 577) Use the `AuthorizationScopes` property to specify a list of authorization scopes configured on the method. In the Integration (p. 584): • Use the `ConnectionId` property to specify the ID of the VpcLink used for the integration when `connectionType=VPC_LINK`. • Use the `ConnectionType` property to specify the type of the network connection to the integration endpoint. • Use the `TimeoutInMillis`	September 20, 2018

property to specify a custom timeout between 50 and 29,000 milliseconds.

AWS::ApiGateway::Stage (p. 606)

Use the `AccessLogSetting` property to specify settings for logging access in this stage.

Use the `CanarySetting` property to specify settings for the canary deployment in this stage.

AWS::ApiGateway::UsagePlan (p. 614)

In the Amazon API Gateway UsagePlan ApiStage (p. 616) property type, use the `Throttle` property to specify a map containing method-level throttling information for API stage in a usage plan.

AWS::CodeBuild::Project (p. 911)

Use the `LogsConfig` property specify logs for a project. Logs can be CloudWatch Logs, uploaded to a specified S3 bucket, or both.

In the AWS CodeBuild Project LogsConfig (p. 924) property type:

- Use the `CloudWatchLogs` property to specify details about CloudWatch Logs.
- Use the `S3Logs` property to specify details about logs that are uploaded to an S3 bucket.

AWS::CodeDeploy::DeploymentGroup (p. 940)

Use the `Ec2TagSet` property to specify information about groups of tags applied to EC2 instances. The deployment group will include only EC2 instances identified by all the tag groups.

Use the `OnPremisesInstanceTagSet` property to specify information about groups of tags applied to on-premises instances. The deployment group will include only on-premises instances identified by all the tag groups.

The `DeliverLogsPermissionArn` and `LogGroupName` properties are no longer required.

AWS::EC2::FlowLog (p. 1150)

Use the `LogDestination` property to specify the destination to which the flow log data is to be published.

Use the `LogDestinationType` property to specify the type of destination to which the flow log data is to be published. Flow log data can be published to CloudWatch Logs or Amazon S3.

AWS::EC2::SpotFleet (p. 1246)

In the `SpotFleetRequestConfigData` property type, use the `InstanceInterruptionBehavior` property to specify the behavior when a Spot Instance is interrupted.

In the `SpotFleetRequestConfigData` property type, use the `LoadBalancersConfig` property to specify one or more Classic Load Balancers and target groups to attach to the Spot Fleet request. Spot Fleet registers the running Spot Instances with the specified Classic Load Balancers and target groups.

In the `Placement` property type, use the `Tenancy`

property to specify the tenancy of the instance (if the instance is running in a VPC). An instance with a tenancy of dedicated runs on single-tenant hardware. The host tenancy is not supported for Spot Instances.

AWS::EC2::VPCEndpoint (p. 1293)

Use the following attributes with the `Fn::GetAtt` function to return attribute values.

- Use `CreationTimestamp` to return the date and time the VPC endpoint was created.
- Use `DnsEntries` to return the DNS entries for the endpoint.
- Use `NetworkInterfaceIds` to return the network interfaces for the endpoint.

AWS::ECS::Service (p. 1328)

The `ServiceRegistries` property now requires replacement upon update.

Use the `SchedulingStrategy` property to specify the scheduling strategy to use for the service.

In the ServiceRegistry (p. 1344) property type:

- Use the `ContainerName` property to specify the container name value, already specified in the task definition, to be used for your service discovery service.
- Use the `ContainerPort` property to specify the port value, already specified in the task definition, to be used for

	your service discovery service.
AWS::ECS::TaskDefinition (p. 1345)	
	In the LinuxParameters (p. 1365) property type: • Use the `Tmpfs` property to specify the container path, mount options, and size of the tmpfs mount. • Use the `SharedMemorySize` property to specify the size (in MiB) of the `/dev/shm` volume. In the Volumes (p. 1373) property type, use the `DockerVolumeConfiguration` property to specify the configuration of a Docker volume. In the ContainerDefinition (p. 1352) property type, use the `RepositoryCredentials` property to specify the repository credentials for private registry authentication.
AWS::ElastiCache::ReplicationGroup (p. 1395)	
	The `NodeGroupConfiguration` and `NumNodeGroups` properties are now conditional for some update operations. In the NodeGroupConfiguration (p. 1406) property type, use the `NodeGroupId` property to specify either the ElastiCache for Redis supplied 4-digit id or a user supplied id for the node group these configuration values apply to.
AWS::RDS::DBCluster (p. 1887)	
	Use the `EngineMode` property to specify the DB engine mode of the DB cluster.

	Use the `ScalingConfiguration` property to specify the scaling properties of the DB cluster, for DB clusters in `serverless` DB engine mode.	
New resources (p. 2379)	The following resources were added: AWS::IoT1Click::Device, AWS::IoT1Click::Placement, and AWS::IoT1Click::Project. AWS::IoT1Click::Device (p. 1718) Use the `AWS::IoT1Click::Device` resource to change the enabled state of an AWS IoT 1-Click compatible device. AWS::IoT1Click::Placement (p. 1720) Use the `AWS::IoT1Click::Placement` resource to create an empty AWS IoT 1-Click placement. AWS::IoT1Click::Project (p. 1723) Use the `AWS::IoT1Click::Project` resource to create an empty project with a placement template.	September 20, 2018
New resource (p. 2379)	Added the AWS::CloudFormation::Macro resource. AWS::CloudFormation::Macro (p. 821) Use the `AWS::CloudFormation::Macro` resource to create a template macro to perform custom processing on AWS CloudFormation templates.	September 6, 2018
Macros now available (p. 2379)	Use macros to to perform custom processing on templates, from simple actions like find-and-replace operations to extensive transformations of entire templates. See Using AWS CloudFormation Macros to Perform Custom Processing on Templates (p. 465) for more information.	September 6, 2018

Updated resources (p. 2379)	Added the Logs property to AWS::AmazonMQ::Broker. Added the SecondaryArtifacts and SecondarySources properties to AWS::CodeBuild::Project. AWS::AmazonMQ::Broker (p. 520) Use the `Logs` property to enable general or audit logging for an Amazon MQ broker. AWS::CodeBuild::Project (p. 911) In the AWS CodeBuild Project Artifacts (p. 919) property type, you can use the `SecondaryArtifacts` property to specify secondary artifacts for a build project. You can use the `SecondarySources` property to specify secondary inputs for a build project.	August 30, 2018
Updated resources (p. 2379)	Added the Configuration property to AWS::Glue::Crawler. Added the JsonClassifier and XMLClassifier properties to AWS::Glue::Classifier. AWS::Glue::Crawler (p. 1592) Use the `Configuration` property to specify crawler configuration information. This versioned JSON string allows users to specify aspects of a crawler's behavior. AWS::Glue::Classifier (p. 1584) Use the `JsonClassifier` property to specify AWS Glue classifier for JSON. Use the `XMLClassifier` property to specify AWS Glue classifier for XML content.	August 23, 2018

AWS CloudFormation now supports VPC endpoints powered by PrivateLink. (p. 2379)	You can use a VPC endpoint to create a private connection between your VPC and AWS CloudFormation without requiring access over the Internet, through a NAT instance, a VPN connection, or AWS Direct Connect. For more information, see Setting Up VPC Endpoints for AWS CloudFormation (p. 24).	August 22, 2018
Dynamic references support secure strings (p. 2379)	Use new dynamic references to specify values that are stored and managed in other services, including Systems Manager Parameter Store SecureString type parameters, in your stack templates. For more information, see Using Dynamic References to Specify Template Values (p. 181).	August 16, 2018

Updated resources (p. 2379)	The following resources were updated: AWS::ApiGateway::DomainName, AWS::CertificateManager::Certificate, AWS::EC2::VPCPeeringConnection, AWS::EFS::FileSystem, AWS::EMR::Cluster, AWS::RDS::DBClusterParameterGroup, AWS::SNS::Subscription, and AWS::SQS::Queue. AWS::ApiGateway::DomainName (p. 566) Use the following attributes with the `Fn::GetAtt` intrinsic function: • The `DistributionHostedZoneId` attribute returns the region-agnostic Amazon Route 53 Hosted Zone ID of the edge-optimized endpoint. • The `RegionalDomainName` attribute returns the domain name associated with the regional endpoint for this custom domain name. • The `RegionalHostedZoneId` attribute returns the region-specific Amazon Route 53 Hosted Zone ID of the regional endpoint. AWS::CertificateManager::Certificate (p. 788) Use the `ValidationMethod` property to specify the method you want to use if you are requesting a public certificate to validate that you own or control a domain. AWS::EC2::VPCPeeringConnection (p. 1303) Use the `PeerRegion` property to specify the region code for the accepter VPC, if the accepter VPC is located in a region other than the region in which you make the request.	August 15, 2018

AWS::EFS::FileSystem (p. 1375)	• Use the `ProvisionedThroughputInMibps` property to specify the throughput, measured in MiB/s, that you want to provision for a file system that you're creating. • Use the `ThroughputMode` property to specify the throughput mode for the file system to be created.
AWS::EMR::Cluster (p. 1501)	Use the `KerberosAttributes` property to specify attributes for Kerberos configuration when Kerberos authentication is enabled using a security configuration.
AWS::RDS::DBClusterParameterGroup (p. 1896)	The `Tags` property now requires no interruption to update.
AWS::SNS::Subscription (p. 2124)	• Use the `DeliveryPolicy` property to specify the JSON serialization of the subscription's delivery policy. • Use the `FilterPolicy` property to specify the filter policy JSON that is assigned to the subscription. • Use the `RawMessageDelivery` property to specify if raw message delivery is enabled for the subscription. • Use the `Region` property to specify the region in which the topic resides.
AWS::SQS::Queue (p. 2133)	Use the `Tags` property to specify the tags that you want to attach to this queue.

Updated resource (p. 2379)	Added the SSESpecification property to AWS::DAX::Cluster. AWS::DAX::Cluster (p. 1070) Use the `SSESpecification` property to specify the settings to enable server-side encryption.	August 9, 2018
New resource (p. 2379)	Added the AWS::EC2::VPCEndpointServicePermissions resource. AWS::EC2::VPCEndpointServicePermissions (p. 1299) Grant or revoke permissions for service consumers to connect the VPC endpoint service.	August 9, 2018
Updated resource (p. 2379)	Added the OverrideArtifactName property to AWS::CodeBuild::Project. AWS::CodeBuild::Project (p. 911) In the AWS CodeBuild Project Artifacts (p. 919) property type, set the `OverrideArtifactName` property to true to override the artifact name with a name specified in the buildspec file. The name specified in a buildspec file is calculated at build time and uses the Shell command language. For example, you can append a date and time to your artifact name so that it is always unique.	August 7, 2018

Updated resource (p. 2379)	Added the EncryptionDisabled property to AWS::CodeBuild::Project. AWS::CodeBuild::Project (p. 911) In the AWS CodeBuild Project Artifacts (p. 919) property type, set the `EncryptionDisabled` property to true to disable encryption for build output artifacts. This option is only valid if your artifact type is Amazon S3. If this is set to true with another artifact type, an invalidInputException will be thrown.	July 26, 2018
Updated resource (p. 2379)	Added the Timeout property to AWS::Batch::JobDefinition. AWS::Batch::JobDefinition (p. 760) Use the `Timeout` property type to specify a job timeout configuration.	July 19, 2018
New resource (p. 2379)	The following resource was added: AWS::IAM::ServiceLinkedRole. AWS::IAM::ServiceLinkedRole (p. 1676) Use the `AWS::IAM::ServiceLinkedRole` resource to create a service-linked role in IAM. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles are predefined by the service and include all the permissions that the service requires to call other AWS services on your behalf.	July 19, 2018

Updated resources (p. 2379)	Added the FieldLevelEncryptionId property to AWS::CloudFront::Distribution property types. AWS::CloudFront::Distribution (p. 831) In the CloudFront Distribution CacheBehavior (p. 834) and CloudFront Distribution DefaultCacheBehavior (p. 840) property types, use the `FieldLevelEncryptionId` property to specify the ID for the field-level encryption configuration that you want CloudFront to use for encrypting specific fields of data for a cache behavior or for the default cache behavior.	July 18, 2018
Updated resource (p. 2379)	Added the HttpConfig property to AWS::AppSync::DataSource. AWS::AppSync::DataSource (p. 676) Use the `HttpConfig` property type to specify HttpConfig for an AWS AppSync data source.	July 12, 2018
Updated resource (p. 2379)	Added the ReportBuildStatus property to AWS::CodeBuild::Project. AWS::CodeBuild::Project (p. 911) In the AWS CodeBuild Project Source (p. 927) property type, use the `ReportBuildStatus` property to specify whether to send your source provider the status of a build's start and completion.	July 10, 2018

New resource (p. 2379)	The following resource was added: AWS::CodePipeline::Webhook. AWS::CodePipeline::Webhook (p. 991) Use the `AWS::CodePipeline::Webhook` resource to create a webhook that connects your pipeline to an external event, such as a GitHub source repository change, which triggers your pipeline to start every time the external event occurs.	July 5, 2018
Updated resource (p. 2379)	Added the following properties to AWS::EC2::VPCEndpoint: PrivateDnsEnabled, SecurityGroupIds, SubnetIds, and VpcEndpointType. AWS::EC2::VPCEndpoint (p. 1293) Use the `PrivateDnsEnabled` property to indicate whether to associate a private hosted zone with the specified VPC. Use the `SecurityGroupIds` property to specify the ID of one or more security groups to associate with the endpoint network interface. Use the `SubnetIds` property to specify the ID of one or more subnets in which to create an endpoint network interface. Use the `VpcEndpointType` property to specify the type of endpoint.	June 21, 2018

New resources (p. 2379)	The following resources were added: AWS::EC2::VPCEndpointConnectionNotification and AWS::EC2::VPCEndpointService. AWS::EC2::VPCEndpointConnectionNotification (p. 1297) Use the `AWS::EC2::VPCEndpointConnectionNotification` resource to create a connection notification for the specified VPC endpoint or VPC endpoint service. AWS::EC2::VPCEndpointService (p. 1298) Use the `AWS::EC2::VPCEndpointService` resource to create a VPC endpoint service configuration to which service consumers (AWS accounts, IAM users, and IAM roles) can connect.	June 21, 2018
Updated resource (p. 2379)	Added the following property to AWS::ServiceDiscovery::Service: HealthCheckCustomConfig. AWS::ServiceDiscovery::Service (p. 1979) Use the `HealthCheckCustomConfig` property to specify information about an optional custom health check.	June 14, 2018

New resources (p. 2379)	The following new resources were released: AWS::AmazonMQ::Broker and AWS::AmazonMQ::Configuration. AWS::AmazonMQ::Broker (p. 520) Use the `AWS::AmazonMQ::Broker` resource to create a broker, add configuration changes or modify users for the specified broker, return information about the specified broker, or delete the specified broker. AWS::AmazonMQ::Configuration (p. 530) Use the `AWS::AmazonMQ::Configuration` resource to create a configuration, update the specified configuration, or return information about the specified configuration.	June 14, 2018
New resource (p. 2379)	The following resource was released: : AWS::SSM::ResourceDataSync. AWS::SSM::ResourceDataSync (p. 2185) Use the `AWS::SSM::ResourceDataSync` resource to create or delete a Resource Data Sync for Systems Manager Inventory. You can use Resource Data Sync to send Inventory data collected from all of your Systems Manager managed instances to a single Amazon S3 bucket.	June 11, 2018
New resource (p. 2379)	The following resource was released: AWS::EKS::Cluster. AWS::EKS::Cluster (p. 1382) Use the `AWS::EKS::Cluster` resource to create Amazon EKS clusters.	June 5, 2018

Updated resource (p. 2379)	For the AWS::GuardDuty::Master resource, the InvitationId property is now optional. AWS::GuardDuty::Master (p. 1647) The `InvitationId` property is now optional.	May 31, 2018
New resources (p. 2379)	The following new resources were released: AWS::SageMaker::Endpoint, AWS::SageMaker::EndpointConfig, AWS::SageMaker::Model, AWS::SageMaker::NotebookInstance, and AWS::SageMaker::NotebookInstanceLifecycleConfig. AWS::SageMaker::Endpoint (p. 2040) Use the `AWS::SageMaker::Endpoint` resource to create a SageMaker endpoint to host trained models. AWS::SageMaker::EndpointConfig (p. 2044) Use the `AWS::SageMaker::EndpointConfig` resource to create a configuration for an endpoint. AWS::SageMaker::Model (p. 2050) Use the `AWS::SageMaker::Model` resource to create a model to host at an Amazon SageMaker endpoint. AWS::SageMaker::NotebookInstance (p. 2057) Use the `AWS::SageMaker::NotebookInstance` resource to create an Amazon SageMaker notebook instance. AWS::SageMaker::NotebookInstanceLifecycleConfig (p. 2062) Use the `AWS::SageMaker::NotebookInstanceLifecycleConfig` resource to specify shell scripts that run when you create or start a notebook instance.	May 31, 2018

Stack sets now support customized execution roles (p. 2379)	Use customized execution roles in target accounts to control the stack resources that users or groups can include in their stack sets. For more information, see Prerequisites: Granting Permissions for Stack Set Operations (p. 489).	May 30, 2018
Selective updates of stack instances (p. 2379)	Use the optional Accounts and Regions parameters to specify the accounts and regions in which to update stack instances during a stack set update operation. For more information, see UpdateStackSet in the *AWS CloudFormation API Reference*.	May 30, 2018

New resources (p. 2379)	The following new resources were released: AWS::Neptune::DBCluster, AWS::Neptune::DBClusterParameterGroup, AWS::Neptune::DBInstance, AWS::Neptune::DBParameterGroup, and AWS::Neptune::DBSubnetGroup. AWS::Neptune::DBCluster (p. 1818) Use the `AWS::Neptune::DBCluster` resource to create an Amazon Neptune DB cluster. AWS::Neptune::DBClusterParameterGroup (p. 1822) Use the `AWS::Neptune::DBClusterParameterGroup` resource to create a DB cluster parameter group. AWS::Neptune::DBInstance (p. 1824) Use the `AWS::Neptune::DBInstance` resource to create an Amazon Neptune database instance. AWS::Neptune::DBParameterGroup (p. 1829) Use the `AWS::Neptune::DBParameterGroup` resource to create a custom parameter group for Amazon Neptune. AWS::Neptune::DBSubnetGroup (p. 1831) Use the `AWS::Neptune::DBSubnetGroup` resource to create an Amazon Neptune database subnet group that contains subnets.	May 30, 2018

Updated resources (p. 2379)	The following resources were updated: AWS::ApiGateway::RestApi, AWS::AutoScaling::AutoScalingGroup, AWS::AutoScaling::LaunchConfiguration, AWS::DirectoryService::MicrosoftAD, AWS::DynamoDB::Table, AWS::EC2::Instance, AWS::ECS::Service, AWS::ECS::TaskDefinition, AWS::Elasticsearch::Domain, AWS::IAM::Role, AWS::KinesisFirehose::DeliveryStream, AWS::Lambda::EventSourceMapping, AWS::Logs::MetricFilter, and AWS::SSM::Association. AWS::ApiGateway::RestApi (p. 598) Use the `Policy` property to specify a policy document that contains the permissions for the specified RestAPI. AWS::AutoScaling::AutoScalingGroup (p. 699) Use the `ServiceLinkedRoleARN` property to specify the Amazon Resource Name (ARN) of the service-linked role that the Auto Scaling group uses to call other AWS services on your behalf. AWS::AutoScaling::LaunchConfiguration (p. 715) Use the `LaunchConfigurationName` property to specify the name of the launch configuration. AWS::DirectoryService::MicrosoftAD (p. 1083) Use the `Edition` property to specify the AWS Microsoft AD edition to use. AWS::DynamoDB::Table (p. 1115) Use the `PointInTimeRecoverySpecification` property to specify the settings used to enable point in time recovery.	May 24, 2018

AWS::EC2::Instance (p. 1155)

Use the `LaunchTemplate` property to specify the launch template to use for an Amazon EC2 instance.

AWS::ECS::Service (p. 1328)

Use the `ServiceRegistry` property type to specify the details of the service registry.

AWS::ECS::TaskDefinition (p. 1345)

Use the `HealthCheck` property type to specify a container health check.

AWS::Elasticsearch::Domain (p. 1412)

Use the `EncryptionAtRestOptions` property type to specify whether the domain should encrypt data at rest, and if so, the AWS Key Management Service (KMS) key to use.

AWS::IAM::Role (p. 1670)

Use the `RoleId` attribute to have `Fn::GetAtt` return the stable and unique string identifying the role.

Use the `MaxSessionDuration` property to specify the maximum session duration (in seconds) for the specified role.

AWS::KinesisFirehose::DeliveryStream (p. 1730)

Use the `SplunkDestinationConfiguration` property to specify the configuration of a destination in Splunk for a Kinesis Data Firehose delivery stream.

AWS::Lambda::EventSourceMapping (p. 1793)

The `StartingPosition` property is no longer required.

AWS::Logs::MetricFilter (p. 905)	In the CloudWatch Logs MetricFilter MetricTransformation Property (p. 907) property type, use the `DefaultValue` property to specify the value to emit when a filter pattern does not match a log event.
AWS::SSM::Association (p. 2148)	Use the `OutputLocation` property to specify an Amazon S3 bucket where you want to store the results of an association request.

New resources (p. 2379)	The following new resources were released: AWS::ServiceCatalog::AcceptedPortfolioShare, AWS::ServiceCatalog::CloudFormationProduct, AWS::ServiceCatalog::LaunchNotificationConstraint, AWS::ServiceCatalog::LaunchRoleConstraint, AWS::ServiceCatalog::LaunchTemplateConstraint, AWS::ServiceCatalog::Portfolio, AWS::ServiceCatalog::PortfolioPrincipalAssociation, AWS::ServiceCatalog::PortfolioProductAssociation, AWS::ServiceCatalog::PortfolioShare, AWS::ServiceCatalog::TagOption, and AWS::ServiceCatalog::TagOptionAssociation. AWS::ServiceCatalog::AcceptedPortfolioShare (p. 2066) Use the `AWS::ServiceCatalog::AcceptedPortfolioShare` resource to accept an offer to share the specified portfolio for AWS Service Catalog. AWS::ServiceCatalog::CloudFormationProduct (p. 2067) Use the `AWS::ServiceCatalog::CloudFormationProduct` resource to create a product for AWS Service Catalog. AWS::ServiceCatalog::LaunchNotificationConstraint (p. 2075) Use the `AWS::ServiceCatalog::LaunchNotificationConstraint` resource to create a notification constraint for AWS Service Catalog. AWS::ServiceCatalog::LaunchRoleConstraint (p. 2077) Use the `AWS::ServiceCatalog::LaunchRoleConstraint` resource to create a launch constraint for AWS Service Catalog. AWS::ServiceCatalog::LaunchTemplateConstraint (p. 2078) Use the `AWS::ServiceCatalog::LaunchTemplateConstraint` resource to create a template constraint for AWS Service Catalog. AWS::ServiceCatalog::Portfolio (p. 2080) Use the `AWS::ServiceCatalog::Portfolio` resource to create a	May 24, 2018

	portfolio for AWS Service Catalog. AWS::ServiceCatalog::PortfolioPrincipalAssociation (p. 2082) Use the `AWS::ServiceCatalog::PortfolioPrincipalAssociation` resource to associate a principal with a portfolio for AWS Service Catalog. AWS::ServiceCatalog::PortfolioProductAssociation (p. 2083) Use the `AWS::ServiceCatalog::PortfolioProductAssociation` resource to associate a product with a portfolio for AWS Service Catalog. AWS::ServiceCatalog::PortfolioShare (p. 2084) Use the `AWS::ServiceCatalog::PortfolioShare` resource to share a portfolio for AWS Service Catalog. AWS::ServiceCatalog::TagOption (p. 2086) Use the `AWS::ServiceCatalog::TagOption` resource to create a TagOption. AWS::ServiceCatalog::TagOptionAssociation (p. 2087) Use the `AWS::ServiceCatalog::TagOptionAssociation` resource to associate a TagOption with a resource for AWS Service Catalog.	
AWS CloudFormation now creates S3 buckets with encryption enabled (p. 2379)	For Amazon S3 buckets that AWS CloudFormation creates to store uploaded stack templates, server-side encryption is now enabled by default, thereby encrypting all objects stored in those buckets. For more information, see Selecting a Stack Template (p. 95).	May 24, 2018
New resource (p. 2379)	The following resource was released: AWS::Budgets::Budget. AWS::Budgets::Budget (p. 775) Use the `AWS::Budgets::Budget` resource to create a budget.	May 22, 2018

FIPS endpoints added (p. 2379)	AWS CloudFormation now offers new endpoints which use FIPS 140-2 validated cryptographic modules in the following public US regions: US-East-1, US-East-2, US-West-1, and US-West-2. See Regions and Endpoints in the *Amazon Web Services General Reference* for the new FIPS-compliant endpoint URLs.	May 17, 2018
New resource (p. 2379)	The following resource was released: AWS::AutoScalingPlans::ScalingPlan. AWS::AutoScalingPlans::ScalingPlan (p. 744) Use the `AWS::AutoScalingPlans::ScalingPlan` resource to create a scaling plan for the scalable resources for your application.	May 9, 2018
New resource (p. 2379)	The following resource was released: AWS::GuardDuty::Filter. AWS::GuardDuty::Filter (p. 1642) Use the `AWS::GuardDuty::Filter` resource to create a filter for your GuardDuty findings.	May 8, 2018

Updated resources (p. 2379)	The following resources were updated: AWS::AppSync::GraphQLApi and AWS::GuardDuty::Member. AWS::AppSync::GraphQLApi (p. 684) Use the `OpenIDConnectConfig` property to specify the authorization configuration for using an OpenId Connect compliant service with your GraphQL endpoint. AWS::GuardDuty::Member (p. 1649) Use the `DisableEmailNotification` property to specify whether an email notification is to be sent to the accounts that you want to invite to GuardDuty as members. When set to 'True', email notification is not sent to the invitees.	May 1, 2018
New resource (p. 2379)	The following resource was released: AWS::ServiceCatalog::CloudFormationProvisionedProduct. AWS::ServiceCatalog::CloudFormationProvisionedProduct (p. 2071) Use the `AWS::ServiceCatalog::CloudFormationProvisionedProduct` resource to provision the specified product for AWS Service Catalog.	May 1, 2018

Earlier Updates

The following table describes important changes in each release of the AWS CloudFormation User Guide before May 2018.

Change	Release Date	Description	API Version
Stack set naming convention	April 10, 2018	AWS CloudFormation stacks created using stack sets now follow a new naming convention, in which the stack name contains the stack set name.	2010-05-15
New resources	April 10, 2018	AWS::AppSync::ApiKey (p. 674) Use the `AWS::AppSync::ApiKey` resource to create a unique key that you can distribute to clients who are executing GraphQL operations with AWS AppSync.	2010-05-15

Change	Release Date	Description	API Version
		AWS::AppSync::DataSource (p. 676) Use the `AWS::AppSync::DataSource` resource to create data sources for resolvers in AWS AppSync. AWS::AppSync::GraphQLApi (p. 684) Use the `AWS::AppSync::GraphQLApi` resource to create a new AWS AppSync GraphQL API. AWS::AppSync::GraphQLSchema (p. 687) Use the `AWS::AppSync::GraphQLSchema` resource to create the data model for your AWS AppSync GraphQL API. AWS::AppSync::Resolver (p. 692) Use the `AWS::AppSync::Resolver` resource to define the logical GraphQL resolver that you will attach to fields in a schema.	
Updated resource	April 10, 2018	AWS::Config::ConfigurationAggregator (p. 1045) Use the `OrganizationAggregationSource` property type to specify the regions of AWS Config data to aggregate into an AWS Config configuration aggregator and the IAM role to use to retrieve AWS Organizations details.	2010-05-15
New resources	April 4, 2018	AWS::Config::AggregationAuthorization (p. 1028) Use the `AWS::Config::AggregationAuthorization` resource to grant permission to an aggregator account to collect your AWS Config data. AWS::Config::ConfigurationAggregator (p. 1045) Use the `AWS::Config::ConfigurationAggregator` resource to create a configuration aggregator for AWS Config.	2010-05-15
Stack sets now support customized administrator roles	March 29, 2018	Use customized administrator roles to control which users or groups can manage specific stack sets within the same administrator account. For more information, see Prerequisites: Granting Permissions for Stack Set Operations (p. 489).	2010-05-15
New resource	March 29, 2018	AWS::EC2::LaunchTemplate (p. 1178) Use the `AWS::EC2::LaunchTemplate` resource to create a launch template for an Amazon EC2 instance.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	March 29, 2018	AWS::AutoScaling::AutoScalingGroup (p. 699) Use the `LaunchTemplate` property to specify the launch template to use to launch instances. AWS::EC2::SpotFleet (p. 1246) In the Amazon EC2 SpotFleet SpotFleetRequestConfigData (p. 1265) property type, use the `LaunchTemplateConfigs` property to describe a launch template and overrides.	2010-05-15
New `Fn::Cidr` intrinsic function	March 6, 2018	Returns the specified Cidr address block. For more information, see `Fn::Cidr` (p. 2293).	2010-05-15

Change	Release Date	Description	API Version
New resources	March 6, 2018	AWS::ApiGateway::VpcLink (p. 620) Use the `AWS::ApiGateway::VpcLink` resource to specify an API Gateway VPC link for a `AWS::ApiGateway::RestApi` to access resources in an Amazon Virtual Private Cloud (VPC). AWS::GuardDuty::Master (p. 1647) Use the `AWS::GuardDuty::Master` resource to create a GuardDuty master account. AWS::GuardDuty::Member (p. 1649) Use the `AWS::GuardDuty::Member` resource to create a GuardDuty member account. AWS::SES::ConfigurationSet (p. 2088) Use the `AWS::SES::ConfigurationSet` resource to to create groups of rules that you can apply to the emails you send. AWS::SES::ConfigurationSetEventDestination (p. 2090) Use the `AWS::SES::ConfigurationSetEventDestination` resource to specify a configuration set event destination. AWS::SES::ReceiptFilter (p. 2098) Use the `AWS::SES::ReceiptFilter` resource to specify whether to accept or reject mail originating from an IP address or range of IP addresses. AWS::SES::ReceiptRule (p. 2102) Use the `AWS::SES::ReceiptRule` resource to specify which actions Amazon SES should take when it receives mail on behalf of one or more email addresses or domains that you own. AWS::SES::ReceiptRuleSet (p. 2118) Use the `AWS::SES::ReceiptRuleSet` resource to specify an empty rule set for Amazon SES. AWS::SES::Template (p. 2120) Use the `AWS::SES::Template` resource to to specify the content of the email, composed of a subject line, an HTML part, and a text-only part.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	March 6, 2018	AWS::AutoScaling::AutoScalingGroup (p. 699) Use the `AutoScalingGroupName` property to specify the name of the Auto Scaling group. AWS::ApiGateway::RestApi (p. 598) Use the `ApiKeySourceType` property to specify the source of the API key for metering requests according to a usage plan. Use the `MinimumCompressionSize` property to specify a nullable integer that is used to enable compression or disable compression on an API. AWS::ApplicationAutoScaling::ScalingPolicy (p. 639) In the Application Auto Scaling ScalingPolicy TargetTrackingScalingPolicyConfiguration (p. 651) property type, use the `DisableScaleIn` property to specify whether scale in by the target tracking policy is disabled. AWS::EC2::SpotFleet (p. 1246) In the LaunchSpecifications (p. 1248) property type, use the `TagSpecifications` property to specify the tags to apply during SpotFleet creation. AWS::Elasticsearch::Domain (p. 1412) Use the `Arn` attribute to have `Fn::GetAtt` return the Amazon Resource Name (ARN) of the domain. The `DomainArn` attribute of `Fn::GetAtt` has been deprecated. AWS::RDS::DBCluster (p. 1887) Use the `DBClusterIdentifier` property to specify the DB cluster identifier. AWS::RDS::DBCluster (p. 1887) Use the `DBClusterIdentifier` property to specify the DB cluster identifier. AWS::Redshift::Cluster (p. 1935) Use the `ClusterIdentifier` property to specify the unique identifier of the cluster. AWS::Route53::HealthCheck (p. 1953) In the HealthCheckConfig (p. 1956) property type, use the `Regions` property to specify the regions from which you want Route 53 health checkers to check the specified endpoint.	2010-05-15

Change	Release Date	Description	API Version
		AWS::SSM::Document (p. 2152) Use the `Tags` property to specify the AWS CloudFormation resource tags to apply to the document.	
Updated resource	February 19, 2018	AWS::CodeBuild::Project (p. 911) Use the `Triggers` property to configure a webhook for the project to begin to automatically rebuild the source code every time a code change is pushed to the repository. This is available only for GitHub projects in AWS CloudFormation. It is not available for GitHub Enterprise projects.	2010-05-15
Updated resource	February 8, 2018	AWS::DynamoDB::Table (p. 1115) Use the `SSESpecification` property to specify the settings to enable server-side encryption.	2010-05-15
Updated resource	February 5, 2018	AWS::CodeBuild::Project (p. 911) In the `AWS CodeBuild Project Source` (p. 927) property type: • Use the `GitCloneDepth` property to specify the depth of history to download. • Use the `InsecureSsl` property to specify whether to ignore SSL warnings while connecting to your GitHub Enterprise project repository.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	January 23, 2018	AWS::AutoScaling::LifecycleHook (p. 726) Use the `LifecycleHookName` property to specify the name of the lifecycle hook. AWS::DynamoDB::Table (p. 1115) The `AttributeDefinitions` property now requires replacement when updated. AWS::EC2::Instance (p. 1155) Use the `CreditSpecification` property to specify the credit option for CPU usage of a T2 instance. Use the `ElasticGpuSpecifications` property to specify Elastic GPUs, GPU resources that you can attach to your instance to accelerate the graphics performance of your applications. AWS::EC2::VPC (p. 1285) The `InstanceTenancy` property now requires no interruption when updated from `"dedicated"` to `"default"`. AWS::ECS::Service (p. 1328) Use the `HealthCheckGracePeriodSeconds` property to specify the period of time, in seconds, that the Amazon ECS service scheduler ignores unhealthy Elastic Load Balancing target health checks after a task has first started. AWS::IoT::TopicRule (p. 1699) In the `DynamoDBAction` (p. 1707) property type, the `RangeKeyField` and `RangeKeyValue` properties are no longer required. AWS::KinesisAnalytics::ApplicationOutput (p. 1772) In the `ApplicationOutput` (p. 1772) property type, use the `LambdaOutput` property to identify a Lambda function as the destination when configuring application output. AWS::Kinesis::Stream (p. 1727) Use the `StreamEncryption` property to enable or update server-side encryption using an AWS KMS key for a specified stream. AWS::Lambda::Function (p. 1800) Use the `ReservedConcurrentExecutions` property to specify the maximum of concurrent executions you want reserved for the function.	2010-05-15

Change	Release Date	Description	API Version
		AWS::RDS::DBSubnetGroup (p. 1924) Use the `DBSubnetGroupName` property to specify the name for the DB Subnet Group. AWS::S3::Bucket (p. 1985) Use the `BucketEncryption` property to specify default encryption for a bucket using server-side encryption with Amazon S3-managed keys SSE-S3 or AWS KMS-managed Keys (SSE-KMS) bucket. In the `ReplicationRule` (p. 2024) property type, use the `SourceSelectionCriteria` property to specify additional filters in identifying source objects that you want to replicate. In the `ReplicationDestination` (p. 2022) property type: • Use the `AccessControlTranslation` property to specify replica ownership of the AWS account that owns the destination bucket. • Use the `Account` property to specify destination bucket owner account ID. • Use the `EncryptionConfiguration` property to specify encryption-related information for a bucket that is a destination for replicated objects. AWS::SSM::Association (p. 2148) Use the `AssociationName` property to specify the name of the association between an SSM document and EC2 instances that contain a configuration agent to process the document.	
Rollback triggers added to the AWS CloudFormation console.	January 15, 2018	Rollback triggers enable you to have AWS CloudFormation monitor the state of your application during stack creation and updating, and to roll back that operation if the application breaches the threshold of any of the alarms you've specified. For more information, see Monitor and Roll Back Stack Operations.	2010-05-15
Updated resource	January 12, 2018	AWS::SSM::Parameter (p. 2174) Use the `AllowedPattern` property to specify a regular expression used to validate the parameter value.	2010-05-15

Change	Release Date	Description	API Version
New resources	December 5, 2017	AWS::Inspector::AssessmentTarget (p. 1683) Use the `AWS::Inspector::AsssmentTarget` resource to create an Amazon Inspector assessment target. AWS::Inspector::AssessmentTemplate (p. 1684) Use the `AWS::Inspector::AssessmentTemplate` resource to create an Amazon Inspector assessment template. AWS::Inspector::ResourceGroup (p. 1687) Use the `AWS::Inspector::ResourceGroup` resource to create an Amazon Inspector resource group, which defines tags that identify AWS resources that make up an Amazon Inspector assessment target. AWS::ServiceDiscovery::Instance (p. 1974) Use the `AWS::ServiceDiscovery::Instance` resource to specify information about an instance that Amazon Route 53 creates. AWS::ServiceDiscovery::PrivateDnsNamespace (p. 1976) Use the `AWS::ServiceDiscovery::PrivateDnsNamespace` resource to specify information about a private namespace for Amazon Route 53. AWS::ServiceDiscovery::PublicDnsNamespace (p. 1978) Use the `AWS::ServiceDiscovery::PublicDnsNamespace` resource to specify information about a public namespace for Amazon Route 53. AWS::ServiceDiscovery::Service (p. 1979) Use the `AWS::ServiceDiscovery::Service` resource to define a template for up to five records and an optional health check that you want Amazon Route 53 to create when you register an instance.	2010-05-15
Updated resource	December 5, 2017	AWS::KinesisAnalytics::Application (p. 1759) In the `Input` (p. 1762) property type, use the `InputProcessingConfiguration` property to transform records as they are received from the stream.	2010-05-15

Change	Release Date	Description	API Version
Updated resource	December 1, 2017	AWS::CodeBuild::Project (p. 911) Use the `BadgeEnabled` property to generate a publicly accessible URL for a project's build badge. Use the `Cache` property to configure cache settings for build dependencies. Use the `VpcConfig` property to enable AWS CodeBuild to access resources in an Amazon VPC. In the `EnvironmentVariable` (p. 923) property type, use the `Type` property to specify the type of environment variable.	2010-05-15
New resource	November 30, 2017	AWS::Cloud9::EnvironmentEC2 (p. 791) Use the `AWS::Cloud9::EnvironmentEC2` resource to create an Amazon EC2 development environment in AWS Cloud9.	2010-05-15
Updated resources	November 29, 2017	AWS::ECS::TaskDefinition (p. 1345) Use the `Cpu` property to specify the number of cpu units needed for the task. Use the `ExecutionRoleArn` property to specify the ARN of the execution role. Use the `Memory` property to specify the amount (in MiB) of memory needed for the task. Use the `RequiresCompatibilities` property to specify the launch type the task requires. AWS::ECS::Service (p. 1328) Use the `LaunchType` property to specify the launch type on which to run your service. Use the `NetworkConfiguration` property to specify the network configuration for the service. Use the `PlatformVersion` property to specify the platform version on which to run your service.	2010-05-15

Change	Release Date	Description	API Version
New resources	November 28, 2017	AWS::GuardDuty::Detector (p. 1641) Use the `AWS::GuardDuty::Detector` resource to create a single Amazon GuardDuty detector. AWS::GuardDuty::IPSet (p. 1652) Use the `AWS::GuardDuty::IPSet` resource to create an Amazon GuardDuty IP set. AWS::GuardDuty::ThreatIntelSet (p. 1654) Use the `AWS::GuardDuty::ThreatIntelSet` resource to create a ThreatIntelSet.	2010-05-15
Updated resources	November 28, 2017	AWS::CodeDeploy::Application (p. 935) Use the `ComputePlatform` property to specify an AWS Lambda compute platform for AWS CodeDeploy to deploy an application to. AWS::CodeDeploy::DeploymentGroup (p. 940) In the `DeploymentStyle` (p. 959) property type, use the `DeploymentType` property to specify a blue/green deployment on a Lambda compute platform. AWS::EC2::SpotFleet (p. 1246) In the `SpotFleetRequestConfigData` (p. 1265) property type, the `SpotPrice` property is now optional. AWS::Lambda::Alias (p. 1795) Use the `RoutingConfig` property to specify two different versions of an AWS Lambda function, allowing you to dictate what percentage of traffic will invoke each version.	2010-05-15
New `CodeDeployLambdaAliasUpdate` update policy	November 28, 2017	Use the `CodeDeployLambdaAliasUpdate` update policy to perform an AWS CodeDeploy deployment when the version changes on an `AWS::Lambda::Alias` resource. For more information, see UpdatePolicy (p. 2281).	2010-05-15
New `SSM` parameter types	November 21, 2017	Use `SSM` parameter types to use existing parameters from Systems Manager Parameter Store. **Note**: AWS CloudFormation doesn't currently support the `SecureString` type. For more information, see SSM Parameter Types (p. 174).	2010-05-15
New `ResolvedValue` field for `Parameter` data type	November 21, 2017	The `ResolvedValue` field returns the value that's used in the stack definition for an `SSM` parameter. For more information, see the Parameter data type in the *AWS CloudFormation API Reference*.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	November 20, 2017	AWS::ApiGateway::ApiKey (p. 536) Use the `CustomerId` property to specify an AWS Marketplace customer identifier. Use the `GenerateDistinctId` property to specify whether the key identifier is distinct from the created API key value. AWS::ApiGateway::Authorizer (p. 540) Use the `AuthType` property to specify a customer-defined field that's used in Swagger imports and exports without functional impact. AWS::ApiGateway::DomainName (p. 566) Use the `EndpointConfiguration` property to specify the endpoint types of an API Gateway domain name. Use the `RegionalCertificateArn` property to reference a certificate for use by the regional endpoint for a domain name. AWS::ApiGateway::Method (p. 577) In the `Integration` (p. 584) and `IntegrationResponse` (p. 588) property types, use the `ContentHandling` property to specify how to handle request payload content type conversions. AWS::ApiGateway::RestApi (p. 598) Use the `EndpointConfiguration` property to specify the endpoint types of an API Gateway REST API. AWS::ApplicationAutoScaling::ScalableTarget (p. 624) Use the `ScheduledActions` property to specify scheduled actions for an Application Auto Scaling scalable target. AWS::ECR::Repository (p. 1322) Use the `LifecyclePolicy` property to specify a lifecycle policy for an Amazon ECR repository. AWS::ECS::TaskDefinition (p. 1345) In the `ContainerDefinition` (p. 1352) property type, use the `LinuxParameters` property to specify Linux-specific options for an Amazon ECS container. AWS::ElastiCache::ReplicationGroup (p. 1395) Use the `AtRestEncryptionEnabled` property to enable encryption at rest. Use the `AuthToken` property to specify a password that's used to access a password-protected server.	2010-05-15

Change	Release Date	Description	API Version
		Use the `TransitEncryptionEnabled` property to enable in-transit encryption. AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491) Use the `TargetGroupName` attribute with the `Fn::GetAtt` function to get the name of an Elastic Load Balancing target group. AWS::Elasticsearch::Domain (p. 1412) Use the `VPCOptions` property to specify a VPC configuration for the Amazon ES domain. AWS::EMR::Cluster (p. 1501) Use the `EbsRootVolumeSize` property to specify the size of the EBS root volume for an Amazon EMR cluster. AWS::RDS::DBInstance (p. 1898) Use the `SourceRegion` and `KmsKeyId` properties to create an encrypted read replica from a cross-region source DB instance. AWS::Route53::HostedZone (p. 1960) Use the `QueryLoggingConfig` property to specify a configuration for DNS query logging.	
New `NoEcho` field for custom resource `Response` objects	November 20, 2017	You can now use the optional `NoEcho` field to mask the output of a custom resource. For more information, see Custom Resource Response Objects (p. 455). The corresponding `noEcho` parameter is supported by the `send` method. For more information, see cfn-response Module.	2010-05-15
Stack instance overrides added for stack sets.	November 17, 2017	AWS CloudFormation StackSets allows you to override parameter values in stack instances by account and region. You can override parameter values when you create the stack instances, or when updating existing stack instances. For more information, see Override Parameters on Stack Instances (p. 508).	2010-05-15
Updated resource	November 15, 2017	AWS::StepFunctions::StateMachine (p. 2144) You can use `AWS::StepFunctions::StateMachine` to specify a `StateMachineName` when creating a state machine, and both `DefinitionString` and `RoleArn` can be updated without replacing the state machine.	2010-05-15
StackSets now supports a maximum of 500 stack instances per stack set.	November 6, 2017	You can now create up to a maximum of 500 stack instances per stack set. For more information on AWS CloudFormation limits, see AWS CloudFormation Limits (p. 21).	2010-05-15

Change	Release Date	Description	API Version
New resources	November 2, 2017	AWS::CloudFront::CloudFrontOriginAccessIdentity (p. 855) Use the `AWS::CloudFront::CloudFrontOriginAccessIdentity` resource to specify the Amazon CloudFront origin access identity to associate with the origin of a CloudFront distribution. AWS::CloudFront::StreamingDistribution (p. 858) Use the `AWS::CloudFront::StreamingDistribution` resource to specify an Adobe Real-Time Messaging Protocol (RTMP) streaming distribution for CloudFront.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	November 2, 2017	AWS::ApiGateway::Deployment (p. 547) The `StageName` property has been deprecated on the `StageDescription` (p. 554) property type. AWS::ApiGateway::Method (p. 577) Use the `OperationName` property to assign a friendly name to an API Gateway method. Use the `RequestValidatorId` property to associate a request validator with a method. AWS::AutoScaling::AutoScalingGroup (p. 699) Use the `LifecycleHookSpecificationList` property to specify actions to perform when Auto Scaling launches or terminates instances. AWS::CloudFront::Distribution (p. 831) Use the `Tags` property to specify an arbitrary set of tags (key–value pairs) to associate with a CloudFront distribution. In the `CacheBehavior` (p. 834) and `DefaultCacheBehavior` (p. 840) property types, use the `LambdaFunctionAssociations` property to specify Lambda function associations for a CloudFront distribution. In the `CustomOriginConfig` (p. 839) property type, use the `OriginKeepaliveTimeout` property to specify a custom keep-alive timeout, and use the `OriginReadTimeout` property to specify a custom origin read timeout. In the `DistributionConfig` (p. 843) property type, use the `IPV6Enabled` property to specify whether CloudFront responds to IPv6 DNS requests with an IPv6 address for your distribution. AWS::CodeDeploy::DeploymentGroup (p. 940) In the `LoadBalancerInfo` (p. 965) property type, use the `TargetGroupInfoList` property to specify information about a target group in Elastic Load Balancing to use in a deployment. AWS::EC2::SecurityGroup (p. 1225), AWS::EC2::SecurityGroupEgress (p. 1234), and AWS::EC2::SecurityGroupIngress (p. 1238) Use the `Description` property to specify the description of a security group rule. AWS::EC2::Subnet (p. 1270) The `Ipv6CidrBlock` property now supports `No interruption` updates.	2010-05-15

Change	Release Date	Description	API Version
		AWS::EC2::VPNGateway (p. 1318) Use the `AmazonSideAsn` property to specify a private Autonomous System Number (ASN) for the Amazon side of a BGP session. AWS::EC2::VPNConnection (p. 1313) Use the `VpnTunnelOptionsSpecifications` property to configure tunnel options for a VPN connection. AWS::ElasticBeanstalk::ConfigurationTemplate (p. 1433) and AWS::ElasticBeanstalk::Environment (p. 1438) In the `ConfigurationOptionSetting` (p. 1436) and `OptionSetting` (p. 1451) property types, use the `ResourceName` property to specify a resource name for a time-based scaling configuration option. AWS::EMR::Cluster (p. 1501) Use the `CustomAmiId` property to specify a custom Amazon Linux AMI for a cluster. AWS::KinesisFirehose::DeliveryStream (p. 1730) Use the `Arn` attribute with the `Fn::GetAtt` function to get the Amazon Resource Name (ARN) of the delivery stream. AWS::KMS::Key (p. 1788) Use the `Tags` property to specify an arbitrary set of tags (key–value pairs) to associate with a custom master key (CMS). AWS::OpsWorks::Layer (p. 1852) and AWS::OpsWorks::Stack (p. 1867) Use the `Tags` property to specify an arbitrary set of tags (key–value pairs) to associate with an AWS OpsWorks layer or stack. AWS::RDS::OptionGroup (p. 1929) In the `OptionConfiguration` (p. 1932) property type, use the `OptionVersion` property to specify a version for the option. AWS::S3::Bucket (p. 1985) Use the `AnalyticsConfigurations` property to configure an analysis filter for an Amazon S3 bucket.	

Change	Release Date	Description	API Version
New resources	October 24, 2017	AWS::Glue::Classifier (p. 1584) Use the `AWS::Glue::Classifier` resource to create an AWS Glue classifier. AWS::Glue::Connection (p. 1588) Use the `AWS::Glue::Connection` resource to specify an AWS Glue connection to a data source. AWS::Glue::Crawler (p. 1592) Use the `AWS::Glue::Crawler` resource to specify an AWS Glue crawler. AWS::Glue::Database (p. 1601) Use the `AWS::Glue::Database` resource to create an AWS Glue database. AWS::Glue::DevEndpoint (p. 1604) Use the `AWS::Glue::DevEndpoint` resource to specify a development endpoint for remotely debugging ETL scripts. AWS::Glue::Job (p. 1606) Use the `AWS::Glue::Job` resource to specify an AWS Glue job in the data catalog. AWS::Glue::Partition (p. 1612) Use the `AWS::Glue::Partition` resource to create an AWS Glue partition, which represents a slice of table data. AWS::Glue::Table (p. 1621) Use the `AWS::Glue::Table` resource to create an AWS Glue table. AWS::Glue::Trigger (p. 1632) Use the `AWS::Glue::Trigger` resource to specify triggers that run AWS Glue jobs.	2010-05-15

Change	Release Date	Description	API Version
New resources	October 11, 2017	AWS::SSM::MaintenanceWindow (p. 2156) Use the `AWS::SSM::MaintenanceWindow` resource to create an AWS Systems Manager Maintenance Window. AWS::SSM::MaintenanceWindowTarget (p. 2159) Use the `AWS::SSM::MaintenanceWindowTarget` resource to register a target with a Maintenance Window. AWS::SSM::MaintenanceWindowTask (p. 2161) Use the `AWS::SSM::MaintenanceWindowTask` resource to define a Maintenance Window task. AWS::SSM::PatchBaseline (p. 2177) Use the `AWS::SSM::PatchBaseline` resource to define a Systems Manager patch baseline.	2010-05-15
New resource	October 10, 2017	AWS::ElasticLoadBalancingV2::ListenerCertificate (p. 1477) Use the `AWS::ElasticLoadBalancingV2::ListenerCertificate` resource to specify certificates for an Elastic Load Balancing listener.	2010-05-15
New resource	September 27, 2017	AWS::Athena::NamedQuery (p. 697) Use the `AWS::Athena::NamedQuery` resource to create an Amazon Athena query.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	September 27, 2017	AWS::EC2::NatGateway (p. 1199) Use the `Tags` property to specify resource tags for a NAT gateway. AWS::ElasticBeanstalk::Application (p. 1425) Use the `ResourceLifecycleConfig` property to define lifecycle settings for resources that belong to the application, and the service role that Elastic Beanstalk assumes in order to apply lifecycle settings. AWS::ElasticBeanstalk::ConfigurationTemplate (p. 1433) and AWS::ElasticBeanstalk::Environment (p. 1438) Use the `PlatformArn` property to specify a custom platform for Elastic Beanstalk. AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491) In the TargetDescription (p. 1499) property type, use the `AvailabilityZone` property to specify the Availability Zone where the IP address is to be registered. AWS::Events::Rule (p. 882) In the Target (p. 891) property type, use the following properties for input transformation of events and setting Amazon ECS task and Kinesis stream targets. • `EcsParameters` • `InputTransformer` • `KinesisParameters` • `RunCommandParameters` AWS::KinesisFirehose::DeliveryStream (p. 1730) Use the `DeliveryStreamType` property to specify the stream type and the `KinesisStreamSourceConfiguration` property to specify the stream and role ARNs for a Kinesis stream used as the source for a delivery stream. AWS::RDS::DBInstance (p. 1898) For the `Engine` property, if you have specified `oracle-se` or `oracle-se1`, you can update to `oracle-se2` without the database instance being replaced. AWS::S3::Bucket (p. 1985) Use the `AccelerateConfiguration` property to configure the transfer acceleration state for an Amazon S3 bucket.	2010-05-15

Change	Release Date	Description	API Version
Termination protection added for stacks.	September 26, 2017	Enabling termination protection on a stack prevents it from being accidently deleted. A user cannot delete a stack with termination protection enabled. For more information, see Protecting a Stack From Being Deleted (p. 108).	2010-05-15
Changed default `umask` value from version 1.4-22 onwards	September 14, 2017	The default `umask` parameter value for the cfn-hup.conf configuration file is now `022`. For more information, see cfn-hup (p. 2367).	
Updated resources	September 7, 2017	AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484) Use the `SubnetMappings` property to specify the IDs of the subnets to attach to the load balancer. Use the `Type` property to specify the type of load balancer to create. AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491) Use the `TargetType` property to specify the registration type of the targets in this target group.	2010-05-15
Rollback triggers added to the AWS CloudFormation API	August 31, 2017	Rollback triggers enable you to have AWS CloudFormation monitor the state of your application during stack creation and updating, and to roll back that operation if the application breaches the threshold of any of the alarms you've specified. For more information, see RollbackConfiguration in the *AWS CloudFormation API Reference*.	2010-05-15
New `umask` parameter for cfn-hup.conf file	August 31, 2017	Use the `umask` parameter in the cfn-hup.conf configuration file to control file permissions used by the cfn-hup daemon (version 1.4-21). For more information, see cfn-hup (p. 2367).	
Updated resources for VPC Sizing support	August 29, 2017	AWS::EC2::VPCCidrBlock (p. 1288) Use the `CidrBlock` property to associate an IPv4 CIDR block with a VPC. AWS::EC2::VPC (p. 1285) Use the `CidrBlockAssociations` attribute with the `Fn::GetAtt` function to get a list of IPv4 CIDR block association IDs associated with the VPC.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	August 23, 2017	AWS::S3::Bucket (p. 1985) In the `Rule` (p. 2026) property type, use the `TagFilters` property to specify tags to use in identifying a subset of objects for an Amazon S3 bucket. Use the `MetricsConfiguration` property to specify a metrics configuration for the CloudWatch request metrics from an Amazon S3 bucket. AWS::IoT::TopicRule (p. 1699) In the `Action` (p. 1702) property type, use the `DynamoDBv2Action` property to describe an AWS IoT action that writes data to a DynamoDB table. In the `Action` (p. 1702) property type, the `DynamoDBAction` property now supports the `HashKeyType` and `RangeKeyType` properties. AWS::Lambda::Permission (p. 1813) Use the `EventSourceToken` property to specify a unique token that must be supplied by the principal invoking the function.	2010-05-15
New pseudo parameters	August 23, 2017	Use the `AWS::Partition` pseudo parameter to return the partition that a resource is in. Use the `AWS::URLSuffix` pseudo parameter to return the suffix for a domain. For more information, see Pseudo Parameters Reference (p. 2352).	2010-05-15
New resources for DAX support	August 22, 2017	AWS::DAX::Cluster (p. 1070) Use the `AWS::DAX::Cluster` resource to create a DAX cluster for use with Amazon DynamoDB. AWS::DAX::ParameterGroup (p. 1077) Use the `AWS::DAX::ParameterGroup` resource to create a parameter group for use with Amazon DynamoDB. AWS::DAX::SubnetGroup (p. 1079) Use the `AWS::DAX::SubnetGroup` resource to create a subnet group for use with DAX (DynamoDB Accelerator).	2010-05-15

Change	Release Date	Description	API Version
New resources	August 18, 2017	AWS::ApiGateway::DocumentationPart (p. 558) and AWS::ApiGateway::DocumentationVersion (p. 562) Use the `AWS::ApiGateway::DocumentationPart` and `AWS::ApiGateway::DocumentationVersion` resources to create documentation for your API Gateway API. AWS::ApiGateway::GatewayResponse (p. 573) Use the `AWS::ApiGateway::GatewayResponse` resource to create a custom response for your API Gateway API. AWS::ApiGateway::RequestValidator (p. 593) Use the `AWS::ApiGateway::RequestValidator` resource to set up validation rules for incoming requests to your API Gateway API. AWS::EC2::NetworkInterfacePermission (p. 1216) Use the `AWS::EC2::NetworkInterfacePermission` resource to grant an AWS account permission to a network interface.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	August 18, 2017	AWS::ApiGateway::Stage (p. 606) Use the `DocumentationVersion` property to specify a versioned snapshot of the API documentation. AWS::AutoScaling::ScalingPolicy (p. 729) Use the `TargetTrackingConfiguration` property to specify an Auto Scaling target tracking scaling policy configuration. AWS::CloudTrail::Trail (p. 865) Use the `EventSelectors` property for Amazon S3 Data Events support. AWS::CodeDeploy::DeploymentGroup (p. 940) Use the `LoadBalancerInfo` and `DeploymentStyle` properties to specify an Elastic Load Balancing load balancer for an in-place deployment. Use the `AutoRollbackConfiguration` property to configure automatic rollback for the deployment. AWS::EC2::SpotFleet (p. 1246) In the `SpotFleetRequestConfigData` (p. 1265) property type, use the `ReplaceUnhealthyInstances` property to indicate whether the Spot fleet should replace unhealthy instances and the `Type` property to specify the type of request. AWS::EC2::Subnet (p. 1270) Use the `AssignIpv6AddressOnCreation` and `Ipv6CidrBlock` properties to create a subnet with an IPv6 CIDR block. AWS::KinesisFirehose::DeliveryStream (p. 1730) Use the `ExtendedS3DestinationConfiguration` property to configure a destination in Amazon S3. Use the `ProcessingConfiguration` subproperty within each destination configuration to invoke Lambda functions that transform incoming source data and deliver the transformed data to destinations. AWS::RDS::DBCluster (p. 1887) and AWS::RDS::DBInstance (p. 1898) The default DeletionPolicy is now `Snapshot` for `AWS::RDS::DBCluster` resources and for `AWS::RDS::DBInstance` resources that don't specify the `DBClusterIdentifier` property. For more information about how AWS CloudFormation deletes resources, see DeletionPolicy Attribute (p. 2273).	2010-05-15

Change	Release Date	Description	API Version
		AWS::S3::Bucket (p. 1985) In the `Rule` (p. 2026) property type, use the `AbortIncompleteMultipartUpload` property to specify a lifecycle rule that aborts incomplete multipart uploads to an Amazon S3 bucket. AWS::SQS::Queue (p. 2133) Use the `KmsMasterKeyId` and `KmsDataKeyReusePeriodSeconds` properties to configure server-side encryption for Amazon SQS. Added the `Arn` attribute to the `Fn::GetAtt` intrinsic function for the following resources: • AWS::CloudTrail::Trail (p. 865). Also added `SnsTopicArn`. • AWS::CloudWatch::Alarm (p. 874) • AWS::DynamoDB::Table (p. 1115) • AWS::ECS::Cluster (p. 1327) • AWS::IoT::Policy (p. 1691) • AWS::IoT::TopicRule (p. 1699) • AWS::Logs::Destination (p. 899)	
Support for stack tags in AWS CodePipeline artifacts	August 18, 2017	You can now specify tags for stacks in template configuration files for use as artifacts for AWS CodePipeline pipelines. Specified tags are applied to stacks created using the template configuration file. For more information, see AWS CloudFormation Artifacts (p. 87).	2010-05-15
Create encrypted file systems	August 14, 2017	AWS::EFS::FileSystem (p. 1375) Use the `Encrypted` property to encrypt an Amazon EFS file system during creation. Use the `KmsKeyId` property to optionally specify a custom customer master key to use to protect the encrypted file system.	2010-05-15
New resources for AWS Batch support	August 8, 2017	AWS::Batch::ComputeEnvironment (p. 753) Use the `AWS::Batch::ComputeEnvironment` resource to define your AWS Batch compute environment. AWS::Batch::JobDefinition (p. 760) Use the `AWS::Batch::JobDefinition` resource to specify the parameters for an AWS Batch job definition. AWS::Batch::JobQueue (p. 772) Use the `AWS::Batch::JobQueue` resource to define your AWS Batch job queue.	2010-05-15

Change	Release Date	Description	API Version
New resources for Amazon Kinesis Data Analytics support	July 28, 2017	AWS::KinesisAnalytics::Application (p. 1759) Use the `AWS::KinesisAnalytics::Application` resource to create an Amazon Kinesis Data Analytics application. AWS::KinesisAnalytics::ApplicationOutput (p. 1772) Use the `AWS::KinesisAnalytics::ApplicationOutput` resource to add an external destination to your Amazon Kinesis Data Analytics application. AWS::KinesisAnalytics::ApplicationReferenceDataSource (p. 1777) Use the `AWS::KinesisAnalytics::ApplicationReferenceDataSource` resource to add a reference data source to an existing Amazon Kinesis Data Analytics application.	2010-05-15
Use StackSets to centrally manage stacks across accounts and regions	July 25, 2017	StackSets enables you to create, update, or delete stacks across multiple accounts and regions in a single operation. Using an administrator account, you define and manage an AWS CloudFormation template, and use the template as the basis for provisioning stacks into selected target accounts across specified regions. For more information about StackSets, see Working with AWS CloudFormation StackSets (p. 484).	2010-05-15
View stack events by client request token	July 14, 2017	In the console, stack operations display the client request token on the **Events** tab. All events triggered by a given stack operation are assigned the same client request token, which you can use to track operations. For more information, see Viewing Stack Data and Resources (p. 101) and StackEvent in the *AWS CloudFormation API Reference*.	2010-05-15
Use stack quick-create links	July 14, 2017	Use quick-create links to get stacks up and running quickly. You can specify the template URL, stack name, and template parameters to prepopulate a single **Create Stack Wizard** page. For more information, see Creating Quick-Create Links for Stacks (p. 105).	

Change	Release Date	Description	API Version
New resources for AWS Database Migration Service support	July 12, 2017	AWS::DMS::Certificate (p. 1091) Use the `AWS::DMS::Certificate` resource to create an SSL certificate that encrypts connections between AWS DMS endpoints and the replication instance. AWS::DMS::Endpoint (p. 1093) Use the `AWS::DMS::Endpoint` resource to create an AWS DMS endpoint. AWS::DMS::EventSubscription (p. 1102) Use the `AWS::DMS::EventSubscription` resource to get notifications for AWS DMS events through the Amazon Simple Notification Service. AWS::DMS::ReplicationInstance (p. 1105) Use the `AWS::DMS::ReplicationInstance` resource to create an AWS DMS replication instance. AWS::DMS::ReplicationSubnetGroup (p. 1109) Use the `AWS::DMS::ReplicationSubnetGroup` resource to create an AWS DMS replication subnet group. AWS::DMS::ReplicationTask (p. 1111) Use the `AWS::DMS::ReplicationTask` resource to create an AWS DMS replication task.	2010-05-15
New resources	July 5, 2017	AWS::CloudWatch::Dashboard (p. 880) Use the `AWS::CloudWatch::Dashboard` resource to specify a custom CloudWatch dashboard for your CloudWatch console. AWS::ApiGateway::DomainName (p. 566) Use the `AWS::ApiGateway::DomainName` resource to specify a custom, friendly URL for your API that's deployed to Amazon API Gateway. AWS::EC2::EgressOnlyInternetGateway (p. 1142) Use the `AWS::EC2::EgressOnlyInternetGateway` resource to create an egress-only internet gateway for your VPC. AWS::EMR::InstanceFleetConfig (p. 1541) Use the `InstanceFleetConfig` resource to configure a Spot Instance fleet for an Amazon EMR cluster.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	July 5, 2017	AWS::ApiGateway::RestApi (p. 598) Use the `BinaryMediaTypes` property to specify supported binary media types. AWS::ApplicationAutoScaling::ScalingPolicy (p. 639) Use the `TargetTrackingScalingPolicyConfiguration` property to specify a a target tracking scaling policy configuration. AWS::CloudTrail::Trail (p. 865) Use the `TrailName` property to specify a custom name for an AWS CloudTrail resource. Use the `Tags` property to specify resource tags. AWS::CodeDeploy::DeploymentGroup (p. 940) Use the `AlarmConfiguration` property to configure alarms for the deployment group. Use the `TriggerConfigurations` property to configure notification triggers for the deployment group. AWS::EMR::Cluster (p. 1501) Use the `CoreInstanceFleet` property and the `MasterInstanceFleet` property in the Amazon EMR Cluster JobFlowInstancesConfig (p. 1529) property type to configure the Spot Instance fleet for an Amazon EMR cluster. AWS::DynamoDB::Table (p. 1115) Use the `TimeToLiveSpecification` property to specify the Time to Live (TTL) settings for an Amazon DynamoDB table. Use the `Tags` property to specify resource tags for a DynamoDB table. AWS::EC2::Instance (p. 1155) The `IamInstanceProfile` property now supports `No interruption` updates. AWS::EC2::Route (p. 1219) Use the `EgressOnlyInternetGatewayId` property to specify an egress-only Internet gateway for an EC2 route. AWS::Kinesis::Stream (p. 1727) Use the `RetentionPeriodHours` property to specify the number of hours that data records stored in shards remain accessible.	2010-05-15

Change	Release Date	Description	API Version
		AWS::RDS::DBCluster (p. 1887) Use the `ReplicationSourceIdentifier` property to create a DB cluster as a Read Replica of another DB cluster or an Amazon RDS MySQL DB instance. AWS::Redshift::Cluster (p. 1935) Use the `LoggingProperties` property to create audit log files and store them in Amazon S3.	
New resources	June 6, 2017	AWS::EMR::SecurityConfiguration (p. 1565) Use the `AWS::EMR::SecurityConfiguration` resource to create a security configuration, which is stored in the service and can be specified when a cluster is created.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	June 6, 2017	AWS::AutoScaling::LifecycleHook (p. 726) The `NotificationTargetARN` and `RoleARN` properties are now optional. AWS::CloudWatch::Alarm (p. 874) You can now use the `EvaluateLowSampleCountPercentile`, `ExtendedStatistic`, and `TreatMissingData` properties when creating `AWS::CloudWatch::Alarm` resources. AWS::EC2::SpotFleet (p. 1246) AWS CloudFormation supports mutable changes to Spot fleet properties. The following properties of the `SpotFleetRequestConfigData` property support `Replacement` updates: • `AllocationStrategy` • `IamFleetRole` • `LaunchSpecifications` • `SpotPrice` • `TerminateInstancesWithExpiration` • `ValidFrom` • `ValidUntil` The following properties of the `SpotFleetRequestConfigData` property support `No interruption` updates: • `ExcessCapacityTerminationPolicy` • `TargetCapacity` AWS::EMR::InstanceGroupConfig (p. 1550) AWS CloudFormation now supports Auto Scaling for Amazon EMR task instance groups. AWS::Events::Rule (p. 882) The `RoleArn` property is deprecated on the `Rule` resource. Use the `RoleArn` property on the `Target` property type to specify the IAM role to use for a target. AWS::Kinesis::Stream (p. 1727) The `ShardCount` property now supports `No interruption` updates. AWS::Lambda::Function (p. 1800) Use the `TracingConfig` property to configure tracing settings for Lambda functions.	2010-05-15

Change	Release Date	Description	API Version
		AWS::Redshift::Cluster (p. 1935), AWS::Redshift::ClusterParameterGroup (p. 1944), AWS::Redshift::ClusterSecurityGroup (p. 1947), and AWS::Redshift::ClusterSubnetGroup (p. 1951) Use the `Tags` property to specify resource tags. AWS::RDS::DBCluster (p. 1887) Added the `ReadEndpoint.Address` attribute to the `Fn::GetAtt` intrinsic function. AWS::S3::Bucket (p. 1985) Added the `Arn` attribute to the `Fn::GetAtt` intrinsic function.	

Change	Release Date	Description	API Version
New resources	May 11, 2017	The following new resources support using AWS WAF with Elastic Load Balancing (ELB) Application load balancers. AWS::WAFRegional::ByteMatchSet (p. 2220) Use the `AWS::WAFRegional::ByteMatchSet` resource to identify a part of a web request that you want to inspect. AWS::WAFRegional::IPSet (p. 2225) Use the `AWS::WAFRegional::IPSet` resource to specify which web requests to permit or block based on the IP addresses from which the requests originate. AWS::WAFRegional::Rule (p. 2229) Use the `AWS::WAFRegional::Rule` resource to specify a combination of `IPSet`, `ByteMatchSet`, and `SqlInjectionMatchSet` objects that identify the web requests to allow, block, or count. AWS::WAFRegional::SizeConstraintSet (p. 2232) Use the `AWS::WAFRegional::SizeConstraintSet` resource to specify a size constraint used to check the size of a web request and which parts of the request to check. AWS::WAFRegional::SqlInjectionMatchSet (p. 2237) Use the `AWS::WAFRegional::SqlInjectionMatchSet` resource to allow, block, or count requests that contain malicious SQL code in a specific part of web requests. AWS::WAFRegional::WebACL (p. 2241) Use the `AWS::WAFRegional::WebACL` resource to identify the web requests that you want to allow, block, or count. AWS::WAFRegional::WebACLAssociation (p. 2247) Use the `AWS::WAFRegional::WebACLAssociation` resource to associate a web access control group (ACL) with a resource. AWS::WAFRegional::XssMatchSet (p. 2248) Use the `AWS::WAFRegional::XssMatchSet` resource to specify the parts of web requests that you want AWS WAF to inspect for cross-site scripting attacks and the name of the header to inspect.	2010-05-15

Change	Release Date	Description	API Version
New resources	April 28, 2017	AWS::Cognito::IdentityPool (p. 996) Use the `AWS::Cognito::IdentityPool` resource to create an Amazon Cognito identity pool. AWS::Cognito::IdentityPoolRoleAttachment (p. 1004) Use the `AWS::Cognito::IdentityPoolRoleAttachment` resource to manage the role configuration for an Amazon Cognito identity pool. AWS::Cognito::UserPool (p. 1005) Use the `AWS::Cognito::UserPool` resource to create an Amazon Cognito user pool. AWS::Cognito::UserPoolClient (p. 1020) Use the `AWS::Cognito::UserPoolClient` resource to create a user pool client. AWS::Cognito::UserPoolGroup (p. 1022) Use the `AWS::Cognito::UserPoolGroup` resource to create a user group in an Amazon Cognito user pool. AWS::Cognito::UserPoolUser (p. 1024) Use the `AWS::Cognito::UserPoolUser` resource to create an Amazon Cognito user pool user. AWS::Cognito::UserPoolUserToGroupAttachment (p. 1027) Use the `AWS::Cognito::UserPoolUserToGroupAttachment` resource to attach a user to an Amazon Cognito user pool group.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	April 28, 2017	AWS Config ConfigRule SourceDetails (p. 1044) Use the `MaximumExecutionFrequency` subproperty of the `AWS::Config::ConfigRule` resource to run evaluations for a custom rule using a periodic trigger. AWS::EC2::Volume (p. 1279) We now support Elastic Volumes for Amazon Elastic Block Store (Amazon EBS) in CloudFormation. We now support `No interruption` updates on three properties: `VolumeType`, `Size`, and `Iops`. AWS::EC2::SecurityGroup (p. 1225) Use the `GroupName` property to specify a name for your Amazon EC2 security group. AWS::ECS::Service (p. 1328) There are three new properties for `AWS::ECS::Service`: `PlacementConstraints`, `PlacementStrategies`, and `ServiceName`. AWS::ECS::TaskDefinition (p. 1345) Use the `PlacementConstraints` property to define placement constraints for tasks in the service. AWS::ElastiCache::ReplicationGroup (p. 1395) Added the `ConfigurationEndPoint.Address` attribute and the `ConfigurationEndPoint.Port` attribute to the `Fn::GetAtt` intrinsic function. AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484) Use the `IpAddressType` property to specify the type of IP addresses that are used by the load balancer's subnets. AWS::EMR::Cluster (p. 1501) AWS CloudFormation now supports Auto Scaling for Amazon EMR clusters. AWS::IAM::ManagedPolicy (p. 1662) Use the `ManagedPolicyName` property to specify a custom name for your IAM managed policy. AWS::Lambda::Function (p. 1800) Use the `Tags` property to add tags to your Lambda function. AWS::OpsWorks::Instance (p. 1841) Added the following attributes to the `Fn::GetAtt` intrinsic function: `AvailabilityZone`, `PrivateDnsName`, `PrivateIp`, and `PublicDnsName`.	2010-05-15

Change	Release Date	Description	API Version
		AWS::OpsWorks::UserProfile (p. 1882) Use the `SshUsername` property to specify a user's SSH name. Added the `SshUsername` attribute to the `Fn::GetAtt` intrinsic function. AWS::Redshift::Cluster (p. 1935) Use the `IamRoles` property to provide a list of one or more AWS Identity and Access Management roles that the Amazon Redshift cluster can use to access other AWS services.	
Edit templates in YAML and JSON using AWS CloudFormation Designer	April 6, 2017	When you create AWS CloudFormation templates using Designer, you can now edit your template in both YAML and JSON in the integrated editor. You can also convert JSON templates to YAML and vice-versa, depending on your preferred template authoring language. For more information, see What Is AWS CloudFormation Designer? (p. 203).	2010-05-15
New resource	April 6, 2017	AWS::SSM::Parameter (p. 2174) Use the `AWS::SSM::Parameter` resource to create an SSM parameter in Parameter Store.	2010-05-15
`AWS::Include` transform	March 28, 2017	Use the `AWS::Include` transform to reference reusable snippets stored in an Amazon S3 bucket. For more information, see AWS::Include Transform (p. 195).	2010-05-15
Peer your Amazon VPC with another account	March 28, 2017	You can now use AWS CloudFormation to peer your Amazon VPC with a VPC in another AWS account. For more information, see Walkthrough: Peer with an Amazon VPC in Another AWS Account (p. 243).	2010-05-15
New resource	March 28, 2017	AWS::ApiGateway::UsagePlanKey (p. 619) Use the `AWS::ApiGateway::UsagePlanKey` resource to associate a usage plan key and determine which users the usage plan is applied to.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	March 28, 2017	AWS::EC2::VPCPeeringConnection (p. 1303) Use the `PeerOwnerId` property and the `PeerRoleArn` property to peer with a VPC in another AWS account. For more information, see Walkthrough: Peer with an Amazon VPC in Another AWS Account (p. 243). AWS::IAM::InstanceProfile (p. 1660) Use the `InstanceProfileName` property to configure an instance profile. AWS::Lambda::Function (p. 1800) Use the `DeadLetterConfig` property to configure how AWS Lambda handles events that it can't process. Node.js v0.10 is no longer supported for the `Runtime` property. AWS::Route53::HealthCheck (p. 1953) There are seven new resource subproperty types for the Route 53 HealthCheck HealthCheckConfig (p. 1956) `HealthCheckConfig` property: `AlarmIdentifier`, `ChildHealthChecks`, `EnableSNI`, `HealthThreshold`, `InsufficientDataHealthStatus`, `Inverted`, and `MeasureLatency`. AWS::SQS::Queue (p. 2133) Use the `ContentBasedDeduplication` and `FifoQueue` properties to create First-In-First-Out (FIFO) Amazon Simple Queue Service queues. AWS::S3::Bucket (p. 1985) You can now specify IPv6 domain names for your Amazon S3 buckets.	2010-05-15
New resources	February 10, 2017	AWS::StepFunctions::Activity (p. 2142) Use the `AWS::StepFunctions::Activity` resource to create an AWS Step Functions activity. AWS::StepFunctions::StateMachine (p. 2144) Use the `AWS::StepFunctions::StateMachine` resource to create a Step Functions state machine.	2010-05-15
New intrinsic function	January 17, 2017	Use the `Fn::Split` function to split a string into a list of string values. For more information, see `Fn::Split` (p. 2335).	2010-05-15
Console support for listing imports	January 17, 2017	Use the AWS CloudFormation console to see all of the stacks that are importing an exported output value. For more information, see Listing Stacks That Import an Exported Output Value (p. 156).	2010-05-15

Change	Release Date	Description	API Version
Updated resources	January 17, 2017	AWS::AutoScaling::AutoScalingGroup (p. 699) The `LoadBalancerNames` property can be updated without replacing the Auto Scaling group. AWS::ECS::TaskDefinition (p. 1345) Added the `NetworkMode` and `MemoryReservation` properties. AWS::RDS::DBCluster (p. 1887) AWS CloudFormation supports updates to the `Tags` property. AWS::RDS::DBInstance (p. 1898) Added the `Timezone` property. AWS IoT TopicRule FirehoseAction (p. 1711) Added the `Separator` property. AWS::OpsWorks::Instance (p. 1841) Added the `PublicIp` attribute for the `Fn::GetAtt` intrinsic function.	2010-05-15
New resources	December 01, 2016	AWS::CodeBuild::Project (p. 911) Use the `AWS::CodeBuild::Project` resource to create an AWS CodeBuild project that defines how AWS CodeBuild builds your source code. AWS::SSM::Association (p. 2148) Use the `AWS::SSM::Association` resource to associate an Amazon EC2 Systems Manager document with EC2 instances. AWS::EC2::SubnetCidrBlock (p. 1273) Use the `AWS::EC2::SubnetCidrBlock` resource to associate a single IPv6 CIDR block with an Amazon VPC subnet. AWS::EC2::VPCCidrBlock (p. 1288) Use the `AWS::EC2::VPCCidrBlock` resource to associate a single Amazon-provided IPv6 CIDR block with an Amazon VPC VPC.	2010-05-15

Change	Release Date	Description	API Version
Updated resources for IPv6 support	December 01, 2016	AWS::EC2::Instance (p. 1155) Added the `Ipv6AddressCount` and `Ipv6Addresses` properties. AWS::EC2::NetworkAclEntry (p. 1203) Added the `Ipv6CidrBlock` property. AWS::EC2::NetworkInterface (p. 1208) Added the `Ipv6AddressCount` and `Ipv6Addresses` properties. AWS::EC2::Route (p. 1219) Added the `DestinationIpv6CidrBlock` property. AWS::EC2::SecurityGroupEgress (p. 1234) Added the `CidrIpv6` property. AWS::EC2::SecurityGroupIngress (p. 1238) Added the `CidrIpv6` property. AWS::EC2::SpotFleet (p. 1246) Added the `Ipv6AddressCount` and `Ipv6Addresses` properties for the launch specification network interfaces. AWS::EC2::Subnet (p. 1270) Added the `Ipv6CidrBlocks` attribute for the `Fn::GetAtt` function. AWS::EC2::VPC (p. 1285) Added the `Ipv6CidrBlocks` attribute for the `Fn::GetAtt` function. AWS::SSM::Document (p. 2152) Added the `DocumentType` property.	2010-05-15
Resource specification	November 22, 2016	Use the AWS CloudFormation resource specification to builds tools that help you create AWS CloudFormation templates. The specification is a machine-readable, JSON-formatted text file. For more information, see AWS CloudFormation Resource Specification (p. 2259).	2010-05-15
New resources	November 22, 2016	AWS::OpsWorks::UserProfile (p. 1882) Use the `AWS::OpsWorks::UserProfile` resource to configure SSH access for users who require access to instances in an AWS OpsWorks stack. AWS::OpsWorks::Volume (p. 1885) Use the `AWS::OpsWorks::Volume` resource to register an Amazon Elastic Block Store volume with an AWS OpsWorks stack.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	November 22, 2016	AWS::OpsWorks::App (p. 1833) Added the `DataSources` property. AWS::OpsWorks::Instance (p. 1841) Added the `BlockDeviceMappings`, `AgentVersion`, `ElasticIps`, `Hostname`, `Tenancy`, and `Volumes` properties. AWS::OpsWorks::Layer (p. 1852) Added the `CustomJson` and `VolumeConfigurations` properties. AWS::OpsWorks::Stack (p. 1867) Added the `ElasticIps`, `EcsClusterArn`, `RdsDbInstances`, `CloneAppIds`, `ClonePermissions`, and `SourceStackId` properties. AWS::RDS::DBInstance (p. 1898) Added the `CopyTagsToSnapshot` property.	2010-05-15
List imports	November 22, 2016	List imports of an exported output value to track which AWS CloudFormation stacks are importing the value. For more information, see Listing Stacks That Import an Exported Output Value (p. 156).	2010-05-15
Transforms	November 17, 2016	Specify the AWS Serverless Application Model (AWS SAM) that AWS CloudFormation uses to process AWS SAM syntax for serverless applications. For more information, see Transform (p. 193).	2010-05-15
New resource	November 17, 2016	AWS::SNS::Subscription (p. 2124) Use the `AWS::SNS::Subscription` resource to subscribe an endpoint to an Amazon Simple Notification Service topic.	2010-05-15
Updated resource	November 17, 2016	AWS::Lambda::Function (p. 1800) Use the `Environment` property to specify key-value pairs (environment variables) that your AWS Lambda function can access. Use the `KmsKeyArn` property to specify an AWS Key Management Service key that AWS Lambda uses to encrypt and decrypt environment variables.	2010-05-15

Change	Release Date	Description	API Version
New CLI commands	November 17, 2016	Uploading Local Artifacts to an S3 Bucket (p. 118) Use the `aws cloudformation package` command to upload local artifacts that are referenced in an AWS CloudFormation template to an S3 bucket. Quickly Deploying Templates with Transforms (p. 119) Use the `aws cloudformation deploy` command to combine the create and execute change set actions into a single command. This command is useful for quickly creating or updating stacks that contain transforms.	2010-05-15
Updated resource	November 03, 2016	AWS::CloudFront::Distribution (p. 831) For the CloudFront Distribution DistributionConfig (p. 843) property, use the `HttpVersion` property to specify the latest HTTP version that viewers can use to communicate with Amazon CloudFront. For the CloudFront Distribution ForwardedValues (p. 847) property, use the `QueryStringCacheKeys` property to specify the query string parameters that CloudFront uses to determine which content to cache.	2010-05-15
List stack exports	November 03, 2016	Use the AWS CloudFormation console, API, or AWS CLI to see a list of all the exported output values for a region. For more information, see Exporting Stack Output Values (p. 155).	2010-05-15
Continuous delivery with stacks	November 03, 2016	Use AWS CodePipeline to build continuous delivery workflows with AWS CloudFormation stacks. For more information, see Continuous Delivery with AWS CodePipeline (p. 76).	2010-05-15
Skip resources during rollback	November 03, 2016	If you have a stack in the `UPDATE_ROLLBACK_FAILED` state, use the `ResourcesToSkip` parameter for the `ContinueUpdateRollback` action to skip resources that AWS CloudFormation can't rollback. For more information, see the Troubleshooting section in Update Rollback Failed (p. 2377).	2010-05-15
Change sets enhancement	November 03, 2016	You can create a new stack using a change set (p. 99).	2010-05-15

Change	Release Date	Description	API Version
Updated resource	October 12, 2016	AWS::ElastiCache::CacheCluster (p. 1386) Update the `CacheNodeType` property without replacing the cluster. AWS::ElastiCache::ReplicationGroup (p. 1395) You can create a Redis (cluster mode enabled) replication group that can contain multiple node groups (shards), each with a primary cluster and read replicas. AWS::ElastiCache::SubnetGroup (p. 1410) Use the `CacheSubnetGroupName` property to specify a name for an Amazon ElastiCache subnet group.	2010-05-15
New resources	October 06, 2016	AWS::ApiGateway::UsagePlan (p. 614) Use the `AWS::ApiGateway::UsagePlan` resource to specify a usage plan for deployed Amazon API Gateway APIs. AWS::CodeCommit::Repository (p. 931) Use the `AWS::CodeCommit::Repository` resource to create an AWS CodeCommit repository that is hosted by Amazon Web Services.	2010-05-15
Updated resources	October 06, 2016	AWS::ApiGateway::Authorizer (p. 540) Use the `ProviderARNs` property to use Amazon Cognito user pools as Amazon API Gateway API authorizers. AWS::ApiGateway::Deployment (p. 547) The `StageName` property is no longer required. AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491) For the `GetAtt` function, use the `LoadBalancerArns` attribute to retrieve the Amazon Resource Names (ARNs) of the load balancers that route traffic to the target group. AWS::RDS::DBInstance (p. 1898) Use the `Domain` and `DomainIAMRoleName` properties to use Windows Authentication when users connect to the RDS DB instance. AWS::EC2::SecurityGroupEgress (p. 1234) Use the `DestinationPrefixListId` property to specify the AWS service prefix of an Amazon VPC endpoint.	2010-05-15
Cross-stack reference enhancement	October 06, 2016	Use intrinsic functions to customize the `Name` value of an export (p. 200) or to refer to a value in the `ImportValue (p. 2328)` function.	2010-05-15

Change	Release Date	Description	API Version
AWS CloudFormation service role	September 26, 2016	Use an AWS Identity and Access Management (IAM) service role for AWS CloudFormation stack operations. AWS CloudFormation uses the role's credentials to make calls to stack resources on your behalf. For more information, see AWS CloudFormation Service Role (p. 17).	2010-05-15
New feature	September 19, 2016	You can use the `Export` output field and the `Fn::ImportValue` intrinsic function to have one stack refer to resource outputs in another stack. For more information, see Outputs (p. 200), `Fn::ImportValue` (p. 2328), and Walkthrough: Refer to Resource Outputs in Another AWS CloudFormation Stack (p. 250).	2010-05-15
YAML support	September 19, 2016	You can use the YAML format to author AWS CloudFormation templates. YAML also allows you to, for example, add comments to your templates or use the short form for intrinsic functions. For more information, see AWS CloudFormation Template Formats (p. 164).	2010-05-15
New intrinsic function	September 19, 2016	Use the `Fn::Sub` function to substitute variables in an input string with values that you specify. For more information, see `Fn::Sub` (p. 2337).	2010-05-15
New resources	September 19, 2016	AWS::KMS::Alias (p. 1786) Use the `AWS::KMS::Alias` resource to create an alias for an AWS Key Management Service customer master key.	
Updated resources	September 19, 2016	AWS::EC2::SpotFleet (p. 1246) For the `LaunchSpecifications` property, use the `SpotPrice` property to specify a bid price for a specific instance type. AWS::ECS::Cluster (p. 1327) Use the `ClusterName` property to specify a name for an Amazon Elastic Container Service cluster. AWS::ECS::TaskDefinition (p. 1345) Use the `TaskRoleArn` property to specify an AWS Identity and Access Management role that Amazon Elastic Container Service containers use to make AWS calls on your behalf. Use the `Family` property to register a task definition to a specific family. AWS::Elasticsearch::Domain (p. 1412) Use the `ElasticsearchVersion` property to specify which version of Elasticsearch to use.	2010-05-15

Change	Release Date	Description	API Version
New resources	August 11, 2016	Use the following Elastic Load Balancing Application load balancer resources to distribute incoming application traffic to multiple targets, such as EC2 instances, in multiple Availability Zones: • AWS::ElasticLoadBalancingV2::Listener (p. 1473) • AWS::ElasticLoadBalancingV2::ListenerRule (p. 1480) • AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484) • AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491)	2010-05-15
Updated resource	August 11, 2016	AWS::AutoScaling::AutoScalingGroup (p. 699) Use the `TargetGroupARNs` property to associate the Auto Scaling group with one or more Application load balancer target groups. AWS::ECS::Service (p. 1328) For the load `LoadBalancers` property, use the `TargetGroupArn` property to associate an Amazon Elastic Container Service service with an Application load balancer target group.	2010-05-15
New resources	August 09, 2016	AWS CloudFormation added the following resources: AWS::ApplicationAutoScaling::ScalableTarget (p. 624) and AWS::ApplicationAutoScaling::ScalingPolicy (p. 639) Use an Application Auto Scaling scaling policy to define when and how a target resource scales. AWS::CertificateManager::Certificate (p. 788) Provision an AWS Certificate Manager certificate that you can use with other AWS services to enable secure connections.	2010-05-15
Updated resources	August 09, 2016	AWS CloudFormation updated the following resources: AWS::CloudFront::Distribution (p. 831) For the distribution configuration `ViewerCertificate` property, you can specify an AWS Certificate Manager certificate. For the distribution configuration `Origin` property, you can specify custom headers and the SSL protocols for custom origins. AWS::EFS::FileSystem (p. 1375) You can specify the performance mode for an Amazon Elastic File System file system.	2010-05-15

Change	Release Date	Description	API Version
New resources	July 20, 2016	AWS IoT Use AWS IoT to declare an AWS IoT policy, an X.509 certificate, an association between a policy and a principal (an X.509 certificate or other credential), an AWS IoT thing, an association between a principal and a thing, or an AWS IoT rule. • AWS::IoT::Certificate (p. 1689) • AWS::IoT::Policy (p. 1691) • AWS::IoT::PolicyPrincipalAttachment (p. 1693) • AWS::IoT::Thing (p. 1694) • AWS::IoT::ThingPrincipalAttachment (p. 1698) • AWS::IoT::TopicRule (p. 1699)	2010-05-15
Updated resources	July 20, 2016	AWS CloudFormation updated the following resources: AWS::IAM::Group (p. 1658), AWS::IAM::Role (p. 1670), AWS::IAM::User (p. 1678) Use the name properties to specify a custom name for AWS Identity and Access Management (IAM) resources. AWS::ApiGateway::Method (p. 577) For the `Integration` property, you can use the `PassthroughBehavior` property to specify when Amazon API Gateway passes requests to the targeted back end. AWS::ApiGateway::Model (p. 590) and AWS::ApiGateway::RestApi (p. 598) You can specify JSON objects for the `Schema` and `Body` properties.	2010-05-15
Auto Scaling group UpdatePolicy	June 9, 2016	For the `UpdatePolicy` attribute, use the `AutoScalingReplacingUpdate` property to specify whether an Auto Scaling group and the instances it contains are replaced when you update the Auto Scaling group. During a replacement, AWS CloudFormation retains the old Auto Scaling group until it creates the new one successfully so that AWS CloudFormation can roll back to the old Auto Scaling group if the update fails. For more information, see UpdatePolicy (p. 2281).	2010-05-15

Change	Release Date	Description	API Version
New resource	June 9, 2016	AWS CloudFormation added the following resources: AWS::EC2::FlowLog (p. 1150) Creates an Amazon Elastic Compute Cloud flow log that captures IP traffic for a specified network interface, subnet, or VPC. AWS::KinesisFirehose::DeliveryStream (p. 1730) Creates a delivery stream that delivers real-time streaming data to a destination, such as Amazon Simple Storage Service, Amazon Redshift, or Amazon Elasticsearch Service.	2010-05-15
Updated resources	June 9, 2016	AWS CloudFormation updated the following resources: AWS::Kinesis::Stream (p. 1727) Use the `Name` property to specify a name for an Amazon Kinesis stream. AWS::Lambda::Function (p. 1800) For the `Code` property, you can use the `ZipFile` property and cfn response module for `nodejs4.3` runtime environments. AWS::SNS::Topic (p. 2128) AWS CloudFormation enabled updates for the Amazon Simple Notification Service topic resource.	2010-05-15
New resource	April 25, 2016	Use the AWS::EC2::Host (p. 1153) resource to allocate a fully dedicated physical server for launching EC2 instances.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	April 25, 2016	AWS::EC2::Instance (p. 1155) Use the `Affinity` and `HostId` properties to launch instances onto an Amazon Elastic Compute Cloud dedicated host. AWS::ECS::Service (p. 1328) Use the `DeploymentConfiguration` property to configure how many tasks can run during a deployment. AWS::ECS::TaskDefinition (p. 1345) AWS CloudFormation added support for additional Amazon Elastic Container Service container definition properties. AWS::GameLift::Fleet (p. 1578) Use the `MaxSize` and `MinSize` properties to specify the maximum and minimum number of EC2 instances allowed in your Amazon GameLift fleet. AWS::Lambda::Function (p. 1800) Use the `FunctionName` property to specify a name for your AWS Lambda function. You can also use Python 2.7 to specify an inline function.	2010-05-15

Change	Release Date	Description	API Version
New resources	April 18, 2016	Amazon API Gateway Use the Amazon API Gateway resources to publish, maintain, and monitor APIs at any scale. You can create APIs that clients can call to access your back-end services, such as applications running EC2 instances or code running on AWS Lambda. • AWS::ApiGateway::Account (p. 534) • AWS::ApiGateway::ApiKey (p. 536) • AWS::ApiGateway::Authorizer (p. 540) • AWS::ApiGateway::BasePathMapping (p. 544) • AWS::ApiGateway::ClientCertificate (p. 545) • AWS::ApiGateway::Deployment (p. 547) • AWS::ApiGateway::Method (p. 577) • AWS::ApiGateway::Model (p. 590) • AWS::ApiGateway::Resource (p. 596) • AWS::ApiGateway::RestApi (p. 598) • AWS::ApiGateway::Stage (p. 606) AWS::Events::Rule (p. 882) Create an Amazon CloudWatch Events rule that monitors changes to AWS resources in your account (events). If an incoming event matches the conditions that you described in the rule, Amazon CloudWatch Events sends messages to and activates your specified targets, such as AWS Lambda functions or Amazon Simple Notification Service topics. AWS::WAF::SizeConstraintSet (p. 2200) and AWS::WAF::XssMatchSet (p. 2215) Use the two AWS WAF rules to check the size of a web request or to prevent cross-site scripting attacks.	2010-05-15
New resources	March 31, 2016	Use the AWS::Lambda::Alias (p. 1795) resource to create aliases for your AWS Lambda functions and the AWS::Lambda::Version (p. 1816) resource to create versions of your functions.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	March 31, 2016	AWS CloudFormation updated the following resources: AWS::EMR::Cluster (p. 1501) and AWS::EMR::InstanceGroupConfig (p. 1550) Use the `EbsConfiguration` property to configure Amazon Elastic Block Store storage volumes for your Amazon EMR clusters or instance groups. AWS::Lambda::Function (p. 1800) Use the `VpcConfig` property to enable AWS Lambda functions to access resources in a VPC. AWS::S3::Bucket (p. 1985) For the Amazon Simple Storage Service life cycle rules, you can specify multiple transition rules that specify when objects transition to a specified storage class.	2010-05-15
Change sets	March 29, 2016	Before updating stacks, use change sets to see how your changes might affect your running resources. For more information, see Updating Stacks Using Change Sets (p. 124).	2010-05-15
New resources	March 15, 2016	Use the AWS::GameLift::Alias (p. 1572), AWS::GameLift::Build (p. 1575), and AWS::GameLift::Fleet (p. 1578) resources to deploy multiplayer game servers in AWS.	2010-05-15
New resources	February 26, 2016	AWS CloudFormation added the following resources: AWS::ECR::Repository (p. 1322) Create Amazon Elastic Container Registry repositories where users can push and pull Docker images. AWS::EC2::NatGateway (p. 1199) Use the network address translator (NAT) gateway to enable EC2 instances in a private subnet to connect to the Internet. AWS::Elasticsearch::Domain (p. 1412) Create Amazon Elasticsearch Service (Amazon ES) domains that contain the Amazon ES engine instances, which process Amazon ES requests. AWS::EMR::Cluster (p. 1501), AWS::EMR::InstanceGroupConfig (p. 1550), AWS::EMR::Step (p. 1568) Use the Amazon EMR resources to help you analyze and process vast amounts of data. You can create clusters and then run jobs on them.	2010-05-15

Change	Release Date	Description	API Version
Updated resources	February 26, 2016	AWS CloudFormation updated the following resources: AWS::CloudTrail::Trail (p. 865) Use the `IsMultiRegionTrail` property to specify whether to create an AWS CloudTrail trail in the region in which you create a stack or in all regions. AWS::Config::ConfigurationRecorder (p. 1050) For the recording group, use the `IncludeGlobalResourceTypes` property to record all global resource types. AWS::RDS::DBCluster (p. 1887) Use the `KmsKeyId` and `StorageEncrypted` properties to encrypt database instances in the cluster.	2010-05-15
Retain resources	February 26, 2016	For stacks in the `DELETE_FAILED` state, use the `RetainResources` parameter to retain resources that AWS CloudFormation can't delete. For more information, see Delete Stack Fails (p. 2374).	2010-05-15
Update stack tags	February 26, 2016	You can add, modify, or remove stack tags when you update a stack. For more information, see AWS CloudFormation Stacks Updates (p. 120).	2010-05-15
Continue rolling back failed update rollbacks	January 25, 2016	For a stack in the `UPDATE_ROLLBACK_FAILED` state, you can continue rolling back the update to get your stack in a working state. That way, you can return the stack to its original settings and try to update it again. For more information, see Continue Rolling Back an Update (p. 152).	2010-05-15
New sample templates available for the Asia Pacific (Seoul) region.	January 7, 2016	The following collection of AWS CloudFormation sample templates are for the ap-northeast-2 region: • Sample Solutions • Application Frameworks • Services For more information, see Sample Templates (p. 2372).	2010-05-15

Change	Release Date	Description	API Version
New resources	December 28, 2015	AWS CloudFormation added the following resources: AWS::DirectoryService::MicrosoftAD (p. 1083) Use the Microsoft Active Directory resource to create a Microsoft Active Directory directory in AWS. AWS::Logs::Destination (p. 899) and AWS::Logs::LogStream (p. 904) Use the Amazon CloudWatch Logs resources to create a destination for real-time processing of log data or to create log streams, respectively. AWS::WAF::ByteMatchSet (p. 2188), AWS::WAF::IPSet (p. 2193), AWS::WAF::Rule (p. 2197), AWS::WAF::SqlInjectionMatchSet (p. 2205), and AWS::WAF::WebACL (p. 2209) Use the AWS WAF resources to control and monitor web requests to your content.	2010-05-15
Resource updates	December 28, 2015	AWS CloudFormation updated the following resources: AWS::CloudFront::Distribution (p. 831) For the distribution configuration, use the `WebACLId` property to associate an AWS WAF web access control list (ACL) with an Amazon CloudFront distribution. For the cache behavior and default cache behavior, you can specify a default and maximum Time to Live (TTL) value. AWS::DynamoDB::Table (p. 1115) You can create, update, or delete a global secondary index without replacing your Amazon DynamoDB table. AWS::S3::Bucket (p. 1985) Use the `ReplicationConfiguration` property to specify which objects to replicate and where they are stored. Use the properties in the `NotificationConfiguration` property to specify filters so that Amazon Simple Storage Service sends notifications for objects that you specify.	2010-05-15
Parameter grouping and sorting	December 3, 2015	Use the AWS::CloudFormation::Interface (p. 817) metadata key to group and sort parameters in the AWS CloudFormation console when users create or update a stack with your template.	2010-05-15
Update policy attribute	December 3, 2015	For an Auto Scaling update policy attribute (p. 2281), use the `MinSuccessfulInstancesPercent` property to specify the percentage of instances that must signal success for a successful update.	2010-05-15

Change	Release Date	Description	API Version
New resources	December 3, 2015	AWS CloudFormation added the following resources: AWS::CodePipeline::Pipeline (p. 979) and AWS::CodePipeline::CustomActionType (p. 973) Use the AWS CodePipeline resources to create a pipeline that describes how software changes go through a release process. AWS::Config::ConfigurationRecorder (p. 1050), AWS::Config::DeliveryChannel (p. 1053), and AWS::Config::ConfigRule (p. 1037) Use the AWS Config resources to monitor configuration changes to specific AWS resources. AWS::KMS::Key (p. 1788) Use the AWS Key Management Service (AWS KMS) resource to create customer master keys in AWS KMS that users can use to encrypt small amounts of data. AWS::SSM::Document (p. 2152) Use the Amazon EC2 Systems Manager to create a document that specifies on-instance configurations.	2010-05-15

Change	Release Date	Description	API Version
Resources update	December 3, 2015	AWS CloudFormation updated the following resources: AWS::AutoScaling::LaunchConfiguration (p. 715) Specify whether EBS volumes are encrypted. AWS::AutoScaling::ScalingPolicy (p. 729) You can use two different policy types (simple and step scaling) to specify how an Auto Scaling group scales when an Amazon CloudWatch (CloudWatch) alarm is breached. AWS::CloudTrail::Trail (p. 865) Use the CloudWatch properties to send logs to a CloudWatch log group. You can add tags to a trail and specify an AWS KMS key that you want to use to encrypt logs. AWS::CodeDeploy::Application (p. 935), AWS::CodeDeploy::DeploymentConfig (p. 937), and AWS::CodeDeploy::DeploymentGroup (p. 940) Use the `ApplicationName`, `DeploymentConfigName`, and `DeploymentGroupName` properties to specify custom names for AWS CodeDeploy resources. AWS::DynamoDB::Table (p. 1115) Use the `StreamSpecification` property to specify settings for capturing changes to items stored in an Amazon DynamoDB (DynamoDB) table. AWS::EC2::Instance (p. 1155) Use the `SsmAssociations` property to associate an Amazon EC2 Systems Manager document with an instance. AWS::EC2::SpotFleet (p. 1246) Use the `AllocationStrategy` property to specify how to allocate target capacity across Spot pools. Use the `ExcessCapacityTerminationPolicy` property to specify how instances are terminated if the target capacity is below the size of the Spot fleet. AWS::Redshift::Cluster (p. 1935) Use the `KmsKeyId` property to specify an AWS KMS key to encrypt data in an Amazon Redshift cluster. AWS::WorkSpaces::Workspace (p. 2253) Use the encryption properties to encrypt data stored on volumes.	2010-05-15

Change	Release Date	Description	API Version
Resource update	November 4, 2015	For the AWS::EC2::Volume (p. 1279) resource, use the `AutoEnableIO` property to automatically resume I/O operations if a volume's data becomes inconsistent.	2010-05-15
New resources	October 1, 2015	AWS CloudFormation added the following resources: AWS::CodeDeploy::Application (p. 935), AWS::CodeDeploy::DeploymentGroup (p. 940), and AWS::CodeDeploy::DeploymentConfig (p. 937) Use the AWS CodeDeploy resources to create and apply deployments to EC2 or on-premises instances. AWS::DirectoryService::SimpleAD (p. 1087) Use the Simple Active Directory resource to create an AWS Directory Service Simple AD, which is a Microsoft Active Directory-compatible directory. AWS::EC2::PlacementGroup (p. 1218) Use a placement group to create a cluster of instances in a low-latency network. AWS::EC2::SpotFleet (p. 1246) Use a Spot fleet to launch a collection of Spot instances that run interruptible tasks. AWS::Lambda::EventSourceMapping (p. 1793) Use the event source mapping resource to specify a stream as an event source for an AWS Lambda (Lambda) function. AWS::Lambda::Permission (p. 1813) Use a Lambda permission to add a statement to a Lambda function's policy. AWS::Logs::SubscriptionFilter (p. 908) Use the subscription filter to define which log events are delivered to your Kinesis stream. AWS::RDS::DBCluster (p. 1887) and AWS::RDS::DBClusterParameterGroup (p. 1896) Use the cluster and cluster parameter group resources to create an Amazon Aurora DB cluster. AWS::WorkSpaces::Workspace (p. 2253) Use Amazon WorkSpaces to create cloud-based desktop experiences.	2010-05-15

Change	Release Date	Description	API Version
Resource updates	October 1, 2015	AWS CloudFormation updated the following resources: AWS::ElastiCache::ReplicationGroup (p. 1395) Use the `Fn::GetAtt` intrinsic function to get a list of read-only replica addresses and ports. AWS::OpsWorks::Stack (p. 1867) Use the `AgentVersion` property to specify a particular AWS OpsWorks agent. AWS::OpsWorks::App (p. 1833) Use the `Environment` property to specify environment variables for an AWS OpsWorks app. AWS::S3::Bucket (p. 1985) For the NotificationConfiguration (p. 2017) property, you can configure notification settings for Lambda functions and Amazon Simple Queue Service (Amazon SQS) queues.	2010-05-15
IAM condition keys	October 1, 2015	For AWS Identity and Access Management (IAM) policies, use AWS CloudFormation-specific condition keys to specify when an IAM policy takes effect. For more information, see Controlling Access with AWS Identity and Access Management (p. 9).	2010-05-15
AWS CloudFormation Designer	October 1, 2015	Use AWS CloudFormation Designer (p. 203) to create and modify templates using a drag-and-drop interface.	2010-05-15
New resource	August 24, 2015	Use the AWS::EC2::VPCEndpoint (p. 1293) resource to establish a private connection between your VPC and another AWS service.	2010-05-15

Change	Release Date	Description	API Version
Resource updates	August 24, 2015	AWS CloudFormation updated the following resources: AWS::ElasticBeanstalk::Environment (p. 1438) Use the `Tags` property to specify tags (key-value pairs) for an AWS Elastic Beanstalk (Elastic Beanstalk) environment. AWS::Lambda::Function (p. 1800) For the `Code` (p. 1806) property, use the `ZipFile` property to write the source code of your Lambda function directly in a template. Currently, you can use the `ZipFile` property only for `nodejs` runtime environments. You can still point to a file in an S3 bucket for all runtime environments, such as `java8` and `nodejs`. AWS::OpsWorks::Instance (p. 1841) Use the `EbsOptimized` property to indicate whether an instance is optimized for Amazon Elastic Block Store (Amazon EBS) I/O. AWS::RDS::DBInstance (p. 1898) For the `SourceDBInstanceIdentifier` property, you can specify a database instance in another region to create a cross-region read replica.	2010-05-15
Amazon S3 template URL	August 24, 2015	For versioning-enabled buckets, you can specify a version ID in an Amazon S3 template URL when you create or update a stack, such as `https://s3.amazonaws.com/templates/myTemplate.template?versionId=123ab1cdeKdOW5IH4GAcYbEngcpTJTDW`.	2010-05-15
New resource	August 3, 2015	Use the AWS::EFS::FileSystem (p. 1375) resource to create an Amazon Elastic File System (Amazon EFS) file system and the AWS::EFS::MountTarget (p. 1379) resource to create a mount point for a file system.	2010-05-15
Permission requirement change	June 11, 2015	When you create or update an AWS::RDS::DBInstance (p. 1898) resource, you must now also have permission to call the `ec2:DescribeAccountAttributes` action.	2010-05-15

Change	Release Date	Description	API Version
New resources	June 11, 2015	AWS CloudFormation added the following resources: AWS::DataPipeline::Pipeline (p. 1056) Use data pipelines to automate the movement and transformation of data. Amazon Elastic Container Service resources Use the AWS::ECS::Service (p. 1328), AWS::ECS::Cluster (p. 1327), and AWS::ECS::TaskDefinition (p. 1345) resources to create Docker containers on a cluster of EC2 instances. AWS::ElastiCache::ReplicationGroup (p. 1395) Use replication groups to create a collection of nodes with one primary read-write cluster and a maximum of five secondary read-only clusters. AWS::IAM::ManagedPolicy (p. 1662) Use managed policies to create policies in your AWS account that you can use to apply permissions to IAM users, groups, and roles. AWS::Lambda::Function (p. 1800) Use Lambda functions to run code in response to events. AWS::RDS::OptionGroup (p. 1929) Use option groups to help you create and manage Amazon Relational Database Service (Amazon RDS) databases.	2010-05-15

Change	Release Date	Description	API Version
Resource updates	June 11, 2015	AWS CloudFormation updated the following resources: AWS::EC2::Subnet (p. 1270) Use the `MapPublicIpOnLaunch` property to automatically assign public IP addresses to instances in a subnet. AWS::ElastiCache::CacheCluster (p. 1386) Use the `SnapshotName` property to restore snapshot data into a new Redis cache cluster. AWS::IAM::User (p. 1678) For the `LoginProfile` property, use the `PasswordResetRequired` property so that users are required to set a new password when they log in to the AWS Management Console. AWS::OpsWorks::Layer (p. 1852) Use the `LifecycleEventConfiguration` property to configure lifecycle events for an AWS OpsWorks layer. AWS::S3::Bucket (p. 1985) For the `LifecycleConfiguration` property, use the `NoncurrentVersionExpirationInDays` and `NoncurrentVersionTransition` properties to specify lifecycle rules for non-current object versions.	2010-05-15
New parameter types	May 19, 2015	Whenever you use the AWS CloudFormation console to create or update a stack, you can search for AWS-specific parameter type values by ID, name, or Name tag value. AWS CloudFormation also added support for the following AWS-specific parameter types. For more information, see Parameters (p. 169). • `AWS::EC2::AvailabilityZone::Name` • `List<AWS::EC2::AvailabilityZone::Name>` • `AWS::EC2::Instance::Id` • `List<AWS::EC2::Instance::Id>` • `AWS::EC2::Image::Id` • `List<AWS::EC2::Image::Id>` • `AWS::EC2::SecurityGroup::GroupName` • `List<AWS::EC2::SecurityGroup::GroupName>` • `AWS::EC2::Volume::Id` • `List<AWS::EC2::Volume::Id>` • `AWS::Route53::HostedZone::Id` • `List<AWS::Route53::HostedZone::Id>`	2010-05-15

Change	Release Date	Description	API Version
New resources	April 16, 2015	AWS CloudFormation added the following resources: AWS::AutoScaling::LifecycleHook (p. 726) Use Auto Scaling lifecycle hooks to control the state of an instance after it is launched or terminated. AWS::RDS::EventSubscription (p. 1926) Use event subscriptions to get notifications about Amazon RDS events.	2010-05-15

Change	Release Date	Description	API Version
Resource updates	April 16, 2015	AWS CloudFormation updated the following resources: AWS::AutoScaling::AutoScalingGroup (p. 699) Use the `NotificationConfigurations` property to specify multiple notifications. AWS::AutoScaling::LaunchConfiguration (p. 715) Use the `PlacementTenancy` property to specify the tenancy of instances. Use the `ClassicLinkVPCId` and `ClassicLinkVPCSecurityGroups` properties to link EC2-Classic instances to a ClassicLink-enabled VPC. AWS::AutoScaling::ScalingPolicy (p. 729) Use the `MinAdjustmentStep` property to specify the minimum number of instances that are added or removed during a scaling event. AWS::CloudFront::Distribution (p. 831) For viewer certificates, use the `MinimumProtocolVersion` property to specify a minimum protocol version. For cache behaviors, use the `CachedMethods` property to specify which methods Amazon CloudFront (CloudFront) caches responses for. For origins, use the `OriginPath` to specify a path that CloudFront uses to request content. AWS::ElastiCache::CacheCluster (p. 1386) For Memcached cache clusters, use the `AZMode` and `PreferredAvailabilityZones` properties to specify nodes in multiple Availability Zones (AZs). AWS::EC2::Volume (p. 1279) Use the `KmsKeyId` property to specify a master key for encrypted volumes. AWS::OpsWorks::Instance (p. 1841) Use the `TimeBasedAutoScaling` property to automatically scale instances based on a schedule that you specify. AWS::OpsWorks::Layer (p. 1852) Use the `LoadBasedAutoScaling` property to specify load-based scaling policies. For volume configurations, use the `VolumeType` and `Iops` properties to specify a volume type and the number of I/O operations per second, respectively. AWS::RDS::DBInstance (p. 1898) Use the `CharacterSetName` property to specify a character set for supported database engines.	2010-05-15

Change	Release Date	Description	API Version
		Use the `StorageEncrypted` property to indicate whether database instances will be encrypted and the `KmsKeyId` to specify a master key for encrypted database instances. AWS::Route53::HealthCheck (p. 1953) Use the `HealthCheckTags` property to associate tags with health checks. AWS::Route53::HostedZone (p. 1960) Use the `VPCs` property to create private hosted zones. Use the `HostedZoneTags` property to associate tags with hosted zones.	
New template section	April 16, 2015	Add the Metadata (p. 168) section to your templates to include arbitrary JSON objects that describe your templates, such as the design or implementation details.	2010-05-15
Resource update	April 8, 2015	For the AWS::CloudFormation::CustomResource (p. 800) resource, you can specify Lambda function Amazon Resource Names (ARNs) in the `ServiceToken` property.	2010-05-15
Amazon RDS update	December 24, 2014	AWS CloudFormation added two new properties for RDS DB instances. You can associate an option group with a DB instance and specify the DB instance storage type. For more information, see AWS::RDS::DBInstance (p. 1898).	2010-05-15
Elastic Load Balancing update	December 24, 2014	You can use the `ConnectionSettings` property to specify how long connections can remain idle. For more information, see AWS::ElasticLoadBalancing::LoadBalancer (p. 1452).	2010-05-15
Route 53 update	November 6, 2014	You can now provision and manage Route 53 hosted zones (p. 1960), health checks (p. 1953), failover record sets (p. 1965), and geolocation record sets (p. 1971).	2010-05-15
Auto Scaling rolling update enhancement	November 6, 2014	During an update, you can use the `WaitOnResourceSignals` flag to instruct AWS CloudFormation to wait for instances to signal success. That way, AWS CloudFormation won't update the next batch of instances until the current batch is ready. For more information, see UpdatePolicy (p. 2281).	2010-05-15
New VPC Fn:GetAtt attributes	November 6, 2014	Given a VPC ID, you can retrieve the default security group and network ACL for that VPC. For more information, see `Fn::GetAtt` (p. 2313).	2010-05-15
New AWS-specific parameter types	November 6, 2014	You can specify AWS-specific parameter types in your AWS CloudFormation templates. In the AWS CloudFormation console, these parameter types provide a drop-down list of valid values. With the API or CLI, AWS CloudFormation can quickly validate values for these parameter types before creating or updating a stack. For more information, see Parameters (p. 169).	2010-05-15

Change	Release Date	Description	API Version
CreationPolicy attribute	November 6, 2014	With the CreationPolicy attribute, you can instruct AWS CloudFormation to wait until applications are ready on EC2 instances before proceeding with stack creation. You can use a creation policy instead of a wait condition and wait condition handle. For more information, see CreationPolicy (p. 2270).	2010-05-15
Amazon CloudFront forwarded values	September 29, 2014	For cache behaviors, you can forward headers to the origin. See CloudFront Distribution ForwardedValues (p. 847).	2010-05-15
AWS OpsWorks update	September 29, 2014	For Chef 11.10, you can use the `ChefConfiguration` property to enable Berkshelf. You can also use the AWS OpsWorks built-in security groups with your AWS OpsWorks stacks. For more information, see AWS::OpsWorks::Stack (p. 1867).	2010-05-15
Elastic Load Balancing tagging support	September 29, 2014	AWS CloudFormation tags Elastic Load Balancing load balancers with stack-level tags. You can also add your own tags to a load balancer. See AWS::ElasticLoadBalancing::LoadBalancer (p. 1452).	2010-05-15
Amazon Simple Notification Service topic policy update	September 29, 2014	You can now update Amazon SNS topic policies. For more information, see AWS::SNS::TopicPolicy (p. 2131).	2010-05-15
RDS DB instance update	September 5, 2014	You can specify whether a DB instance is Internet-facing by using the `PubliclyAccessible` property in the AWS::RDS::DBInstance (p. 1898) resource.	2010-05-15
UpdatePolicy attribute update	September 05, 2014	You can specify an update policy for an Auto Scaling group that has an associated scheduled action. For more information, see UpdatePolicy (p. 2281).	2010-05-15
Amazon CloudWatch support	July 10, 2014	You can use AWS CloudFormation to provision and manage Amazon CloudWatch Logs (CloudWatch Logs) log groups and metric filters. For more information, see AWS::Logs::LogGroup (p. 902) or AWS::Logs::MetricFilter (p. 905).	2010-05-15

Change	Release Date	Description	API Version
Amazon CloudFront distribution configuration update	June 17, 2014	You can specify additional CloudFront distribution configuration properties: • Custom error responses define custom error messages for 4xx and 5xx HTTP status codes. • Price class defines the maximum price that you want to pay for the CloudFront service. • Restrictions define who can view your content. • Viewer certificate specifies the certificate to use when viewers use HTTPS. • For cache behaviors, you can specify allowed HTTP methods and indicate whether to forward cookies. For more information, see AWS::CloudFront::Distribution (p. 831).	2010-05-15
EC2 instance update	June 17, 2014	You can specify whether an instance stops or terminates when you invoke the instance's operating system shutdown command. For more information, see AWS::EC2::Instance (p. 1155).	2010-05-15
EBS volume update	June 17, 2014	You can use encrypted EBS volumes with supported instance types. For more information, see AWS::EC2::Volume (p. 1279).	2010-05-15
New Amazon VPC peering connection	June 17, 2014	You can use AWS CloudFormation to create an Amazon Virtual Private Cloud (Amazon VPC) peering connection, which establishes a network connection between two VPCs. For more information, see AWS::EC2::VPCPeeringConnection (p. 1303).	2010-05-15
Amazon EC2 Auto Scaling group update	June 17, 2014	You can specify an existing cluster placement group in which to launch instances for an Amazon EC2 Auto Scaling group. For more information, see AWS::AutoScaling::AutoScalingGroup (p. 699).	2010-05-15
AWS CloudTrail support	June 17, 2014	AWS CloudFormation supports AWS CloudTrail, which can capture API calls made from your AWS account and publish the logs at a location you designate. For more information, see AWS::CloudTrail::Trail (p. 865).	2010-05-15
Update stack enhancements	May 12, 2014	AWS CloudFormation supports additional features for updating stacks: • You can update AWS CloudFormation stack parameters without resubmitting the stack's template. • You can add or remove Amazon SNS notification topics for an AWS CloudFormation stack. For more information, see AWS CloudFormation Stacks Updates (p. 120).	2010-05-15

Change	Release Date	Description	API Version
Amazon Kinesis support	May 6, 2014	You can use AWS CloudFormation to create Amazon Kinesis streams that capture and transport data records from data sources. For more information, see AWS::Kinesis::Stream (p. 1727).	2010-05-15
New S3 bucket properties	May 5, 2014	AWS CloudFormation supports additional S3 bucket properties: • Cross-origin resource sharing (CORS) defines cross-origin resource sharing of objects in a bucket. • Lifecycle defines how Amazon S3 manages objects during their lifetime. • Access logging policy captures information about requests made to your bucket. • Notifications define which events to report and which Amazon SNS topic to send messages to. • Versioning enables multiple variants of all objects in a bucket. • Redirect and routing rules govern redirect behavior for requests made to a bucket's website endpoint. For more information, see AWS::S3::Bucket (p. 1985).	2010-05-15
Amazon EC2 Auto Scaling support	May 5, 2014	AWS CloudFormation supports metrics collection for an Auto Scaling group. For more information, see AWS::AutoScaling::AutoScalingGroup (p. 699).	2010-05-15
`Fn::If` update	May 5, 2014	You can use the `Fn::If` intrinsic function in the output section of a template. For more information, see Condition Functions (p. 2295).	2010-05-15
API logging with AWS CloudTrail	April 2, 2014	You can use AWS CloudTrail (CloudTrail) to log AWS CloudFormation requests. With CloudTrail you can get a history of AWS CloudFormation API calls for your account. For more information, see Logging AWS CloudFormation API Calls with AWS CloudTrail (p. 17).	2010-05-15
Elastic Load Balancing update	March 20, 2014	You can specify an access logging policy to capture information about requests made to your load balancer. You can also specify a connection draining policy that describes how to handle in-flight requests when instances are deregistered or become unhealthy. For more information, see AWS::ElasticLoadBalancing::LoadBalancer (p. 1452).	2010-05-15
AWS OpsWorks support	March 3, 2014	You can use AWS CloudFormation to provision and manage AWS OpsWorks stacks. For more information, see AWS::OpsWorks::Stack (p. 1867) or AWS OpsWorks Template Snippets (p. 411).	2010-05-15
Amazon S3 template size limit increase	February 18, 2014	You can specify template sizes up to 460,800 bytes in Amazon S3.	2010-05-15

Change	Release Date	Description	API Version
Amazon Redshift support	February 10, 2014	You can use AWS CloudFormation to provision and manage Amazon Redshift clusters. For more information, see Amazon Redshift Template Snippets (p. 416) or AWS::Redshift::Cluster (p. 1935).	2010-05-15
S3 buckets and bucket policies update	February 10, 2014	You can update some properties of the S3 bucket and bucket policy resources. For more information, see AWS::S3::Bucket (p. 1985) or AWS::S3::BucketPolicy (p. 2037).	2010-05-15
Elastic Beanstalk environments and application versions update	February 10, 2014	You can update Elastic Beanstalk environment configurations and application versions. For more information, see AWS::ElasticBeanstalk::Environment (p. 1438), AWS::ElasticBeanstalk::ConfigurationTemplate (p. 1433), or AWS::ElasticBeanstalk::ApplicationVersion (p. 1430).	2010-05-15
Amazon SQS update	January 29, 2014	You can specify a dead letter queue for an Amazon SQS queue. For more information, see AWS::SQS::Queue (p. 2133).	2010-05-15
Auto Scaling scheduled actions	January 27, 2014	You can scale the number of EC2 instances in an Auto Scaling group based on a schedule. By using a schedule, you can scale applications in response to predictable load changes. For more information, see AWS::AutoScaling::ScheduledAction (p. 741).	2010-05-15
DynamoDB secondary indexes	January 27, 2014	You can create local and global secondary indexes for DynamoDB databases. By using secondary indexes, you can efficiently access data with attributes other than the primary key. For more information, see AWS::DynamoDB::Table (p. 1115).	2010-05-15
Auto Scaling update	January 2, 2014	You can specify an instance ID for an Auto Scaling group or launch configuration. You can also specify additional Auto Scaling block device properties. For more information, see AWS::AutoScaling::AutoScalingGroup (p. 699) or AWS::AutoScaling::LaunchConfiguration (p. 715).	2010-05-15
Amazon SQS update	January 2, 2014	You can update SQS queues and specify additional properties. For more information, see AWS::SQS::Queue (p. 2133).	2010-05-15
Limit increases	January 2, 2014	You can specify up to 60 parameters and 60 outputs in your AWS CloudFormation templates.	2010-05-15
New console	December 19, 2013	The new AWS CloudFormation console adds features like auto-refreshing stack events and alphabetical ordering of stack parameters.	2010-05-15
Cross-zone load balancing	December 19, 2013	With cross-zone load balancing, you can route traffic to back-end instances across all Avalibility Zones (AZs). For more information, see AWS::ElasticLoadBalancing::LoadBalancer (p. 1452).	2010-05-15

Change	Release Date	Description	API Version
AWS Elastic Beanstalk environment tiers	December 19, 2013	You can specify whether AWS Elastic Beanstalk provisions resources to support a web server or to handle background processing tasks. For more information, see AWS::ElasticBeanstalk::Environment (p. 1438).	2010-05-15
Resource names	December 19, 2013	You can assign names (physical IDs) to the following resources: • ElastiCache clusters • Elastic Load Balancing load balancers • RDS DB instances For more information, see Name Type (p. 2256).	2010-05-15
VPN support	November 22, 2013	You can enable a virtual private gateway (VGW) to propagate routes to the routing tables of a VPC. For more information, see AWS::EC2::VPNGatewayRoutePropagation (p. 1320).	2010-05-15
Conditionally create resources and assign properties	November 8, 2013	Using input parameters, you can control the creation and settings of designated stack resources by defining conditions in your AWS CloudFormation templates. For example, you can use conditions to create stack resources for a production environment. Using the same template, you can create similar stack resources with lower capacity for a test environment. For more information, see Condition Functions (p. 2295).	2010-05-15
Prevent accidental updates to stack resources	November 8, 2013	You can prevent stack updates that might result in unintentional changes to stack resources. For example, if you have a stack with a database layer that should rarely be updated, you can set a stack policy that prevents most users from updating that database layer. For more information, see Prevent Updates to Stack Resources (p. 143).	2010-05-15
Name resources	November 8, 2013	Instead of using AWS CloudFormation-generated physical IDs, you can assign names to certain resources. The following AWS CloudFormation resources support naming • CloudWatch alarms • DynamoDB tables • Elastic Beanstalk applications and environments • S3 buckets • SNS topics • Amazon SQS queues For more information, see Name Type (p. 2256).	2010-05-15

Change	Release Date	Description	API Version
Assign custom resource types	November 8, 2013	In your templates, you can specify your own resource type for AWS CloudFormation custom resources (`AWS::CloudFormation::CustomResource`). By using your own custom resource type name, you can quickly identify the type of custom resources that you have in your stack. For example, you can specify `"Type": "Custom::MyCustomResource"`. For more information, see AWS::CloudFormation::CustomResource (p. 800).	2010-05-15
Add pseudo parameter	November 8, 2013	You can now refer to the AWS AccountID inside AWS CloudFormation templates by referring to the `AWS::AccountID` pseudo parameter. For more information, see Pseudo Parameters Reference (p. 2352).	2010-05-15
Specify stacks in IAM policies	November 8, 2013	You can allow or deny IAM users, groups, or roles to operate on specific AWS CloudFormation stacks. For example, you can deny the delete stack action on a specific stack ID. For more information, see Controlling Access with AWS Identity and Access Management (p. 9).	2010-05-15
Federation support	October 14, 2013	AWS CloudFormation supports temporary security credentials from IAM roles, which enable scenarios such as federation and single sign-on to the AWS Management Console. You can also make calls to AWS CloudFormation from EC2 instances without embedding long-term security credentials by using IAM roles. For more information about AWS CloudFormation and IAM, see Controlling Access with AWS Identity and Access Management (p. 9).	2010-05-15
Amazon RDS read replica support	September 24, 2013	You can now create Amazon RDS read replicas from a source DB instance. For more information, see the `SourceDBInstanceIdentifier` property in the AWS::RDS::DBInstance (p. 1898) resource.	2010-05-15
Associate public IP address with instances in an Auto Scaling group	September 19, 2013	You can now associate public IP addresses with instances in an Auto Scaling group. For more information, see AWS::AutoScaling::LaunchConfiguration (p. 715).	2010-05-15
Additional VPC support	September 17, 2013	AWS CloudFormation adds several enhancements to support VPC and VPN functionality • You can associate a public IP address and multiple private IP addresses to Amazon EC2 network interfaces. For more information, see AWS::EC2::NetworkInterface (p. 1208). You can also associate a primary private IP address to an elastic IP address (EIP). • You can enable DNS support and specify DNS host names. For more information, see AWS::EC2::VPC (p. 1285). • You can specify a static route between a virtual private gateway to your VPN gateway. For more information, see AWS::EC2::VPNConnectionRoute (p. 1316).	2010-05-15

Change	Release Date	Description	API Version
Redis and VPC security groups support for Amazon ElastiCache	September 3, 2013	You can now specify Redis as the cache engine for an Amazon ElastiCache (ElastiCache) cluster. You can also now assign VPC security groups to ElastiCache clusters. For more information, see AWS::ElastiCache::CacheCluster (p. 1386).	2010-05-15
Parallel stack creation, update and deletion, and nested stack updates	August 12, 2013	AWS CloudFormation now creates, updates, and deletes resources in parallel, improving the operations' performance. If you update a top-level template, AWS CloudFormation automatically updates nested stacks that have changed. For more information, see AWS CloudFormation Stacks Updates (p. 120).	2010-05-15
VPC security groups can now be set in RDS DB instances	February 28, 2013	You can now assign VPC security groups to an RDS DB instance with AWS CloudFormation. For more information, see the VPCSecurityGroups (p. 1911) property in AWS::RDS::DBInstance (p. 1898).	2010-05-15
Rolling deployments for Amazon EC2 Auto Scaling groups	February 20, 2013	AWS CloudFormation now supports update policies on Amazon EC2 Auto Scaling groups, which describe how instances in the Amazon EC2 Auto Scaling group are replaced or modified when the Amazon EC2 Auto Scaling group adds or removes instances. You can modify these settings at stack creation or during a stack update. For more information and an example, see UpdatePolicy (p. 2281).	2010-05-15
Cancel and rollback action for stack updates	February 20, 2013	AWS CloudFormation supports the ability to cancel a stack update. The stack must be in the UPDATE_IN_PROGRESS state when the update request is made. More information is available in the following topics: • Canceling a Stack Update (p. 142) • `aws cloudformation cancel-update-stack` • CancelUpdateStack in the *AWS CloudFormation API Reference*	2010-05-15
EBS-optimized instances for Amazon EC2 Auto Scaling groups	February 20, 2013	You can now provision EBS-optimized instances in Amazon EC2 Auto Scaling groups for dedicated throughput to Amazon Elastic Block Store (Amazon EBS) in autoscaled instances. The implementation is similar to that of the previously released support for optimized Amazon EBS EC2 instances. For more information, see the new `EbsOptimized` property in AWS::AutoScaling::LaunchConfiguration (p. 715).	2010-05-15

Change	Release Date	Description	API Version
New documentation	December 21, 2012	AWS::EC2::Instance (p. 1155) now provides a `BlockDeviceMappings` property to allow you to set block device mappings for your EC2 instance. With this change, two new types have been added: • Amazon EC2 BlockDeviceMapping (p. 1166) • Amazon Elastic Block Store Block Device (p. 1168)	2010-05-15
New documentation	December 21, 2012	New sections have been added to describe the procedures for creating and viewing stacks using the recently redesigned AWS Management Console. You can find them here: • Creating a Stack (p. 94) • Viewing Stack Data and Resources (p. 101)	2010-05-15
New documentation	November 15, 2012	Information about custom resources is provided in the following topics: • Custom Resources (p. 439) • AWS::CloudFormation::CustomResource (p. 800) • Custom Resource Reference (p. 453)	2010-05-15
Updated documentation	November 15, 2012	AWS CloudFormation now supports specifying provisioned I/O operations per second (IOPS) for RDS DB instances. You can set this value from 1000–10,000 in 1000 IOPS increments by using the new Iops (p. 1906) property in AWS::RDS::DBInstance (p. 1898). For more information about specifying IOPS for RDS DB instances, see Provisioned IOPS in the *Amazon Relational Database Service User Guide*.	2010-05-15

Change	Release Date	Description	API Version
New and updated documentation	August 27, 2012	Topics have been reorganized to more clearly provide specific information about using the AWS Management Console and using the AWS CloudFormation command-line interface (CLI). Information about tagging AWS CloudFormation stacks has been added, including new guides and updated reference topics: • New topic in Using the Console: Setting Stack Options (p. 97). • New information about tags in the *AWS CloudFormation API reference*: CreateStack, Stack, and Tag. New information about working with Windows stacks (p. 159): • Microsoft Windows Amazon Machine Images (AMIs) and AWS CloudFormation Templates (p. 159) • Bootstrapping AWS CloudFormation Windows Stacks (p. 159) New topic: Using Regular Expressions in AWS CloudFormation Templates (p. 477).	2010-05-15

Change	Release Date	Description	API Version
New feature	April 25, 2012	AWS CloudFormation now provides full support for Virtual Private Cloud (VPC) security with Amazon EC2 You can now create and populate an entire VPC with every type of VPC resource (subnets, gateways, network ACLs, route tables, and so forth) using a single AWS CloudFormation template. Templates that demonstrate new VPC features can be downloaded: • Single instance in a single subnet • Multiple subnets with Elastic Load Balancing (ELB) and an Auto Scaling group Documentation for the following resource types has been updated: • AWS::EC2::SecurityGroup (p. 1225) • AWS::EC2::SecurityGroupIngress (p. 1238) • AWS::EC2::SecurityGroupEgress (p. 1234) • AWS::EC2::Instance (p. 1155) • AWS::AutoScaling::AutoScalingGroup (p. 699) • AWS::EC2::EIP (p. 1144) • AWS::EC2::EIPAssociation (p. 1146) • AWS::ElasticLoadBalancing::LoadBalancer (p. 1452) New resource types have been added to the documentation: • AWS::EC2::VPC (p. 1285) • AWS::EC2::InternetGateway (p. 1177) • AWS::EC2::DHCPOptions (p. 1139) • AWS::EC2::DHCPOptions (p. 1223) • AWS::EC2::RouteTable (p. 1219) • AWS::EC2::NetworkAcl (p. 1202) • AWS::EC2::NetworkAclEntry (p. 1203) • AWS::EC2::Subnet (p. 1270) • AWS::EC2::VPNGateway (p. 1318) • AWS::EC2::CustomerGateway (p. 1137)	2010-05-15
New feature	April 13, 2012	AWS CloudFormation now allows you to add or remove elements from a stack when updating it. AWS CloudFormation Stacks Updates (p. 120) has been updated, and a new section has been added to the walkthrough: Change the Stack's Resources (p. 61), which describes how to add and remove resources when updating the stack.	2010-05-15

Change	Release Date	Description	API Version
New feature	February 2, 2012	AWS CloudFormation now provides support for resources in an existing Amazon Virtual Private Cloud (Amazon VPC). With this release, you can: • Launch an EC2 Dedicated instance into an existing Amazon VPC. For more information, see AWS::EC2::Instance (p. 1155). • Set the `SourceDestCheck` attribute of an EC2 instance that resides in an existing Amazon VPC. For more information, see AWS::EC2::Instance (p. 1155). • Create Elastic IP addresses in an existing Amazon VPC. For more information, see AWS::EC2::EIP (p. 1144). • Use AWS CloudFormation to create Amazon VPC security groups and ingress/egress rules in an existing VPC. For more information, see AWS::EC2::SecurityGroup (p. 1225). • Associate an Auto Scaling group with an existing Amazon VPC by setting the `VPCZoneIdentifier` property of your `AWS::AutoScaling::AutoScalingGroup` resource. For more information, see AWS::AutoScaling::AutoScalingGroup (p. 699). • Attach an Elastic Load Balancing load balancer to a Amazon VPC subnet and create security groups for the load balancer. For more information, see AWS::ElasticLoadBalancing::LoadBalancer (p. 1452). • Create an RDS DB instance in an existing Amazon VPC. For more information, see AWS::RDS::DBInstance (p. 1898).	2010-05-15
New feature	February 2, 2012	You can now update properties for the following resources in an existing stack: • AWS::EC2::SecurityGroupIngress (p. 1238) • AWS::EC2::SecurityGroupEgress (p. 1234) • AWS::EC2::EIPAssociation (p. 1146) • AWS::RDS::DBSubnetGroup (p. 1924) • AWS::RDS::DBSecurityGroup (p. 1918) • AWS::RDS::DBSecurityGroupIngress (p. 1922) • AWS::Route53::RecordSetGroup (p. 1972) For a complete list of updatable resources and details about what to consider when updating a stack, see AWS CloudFormation Stacks Updates (p. 120).	2010-05-15
Restructured guide	February 2, 2012	Reorganized existing sections into new sections: Working with AWS CloudFormation Templates (p. 164) and **Managing Stacks**. Moved Template Reference (p. 518) to the top level of the Table of Contents. Moved Estimating the Cost of Your AWS CloudFormation Stack (p. 101) to the Getting Started section.	2010-05-15

Change	Release Date	Description	API Version
New content	February 2, 2012	Added three new sections: • Walkthrough: Updating a Stack (p. 47) is a tutorial that walks through the process of updating a LAMP stack. • Deploying Applications on Amazon EC2 with AWS CloudFormation (p. 262) describes how to use AWS CloudFormation helper scripts to deploy applications using metadata stored in your template. • CloudFormation Helper Scripts Reference (p. 2354) provides reference material for the AWS CloudFormation helper scripts (cfn-init, cfn-get-metadata, cfn-signal, and cfn-hup).	2010-05-15
New feature	May 26, 2011	AWS CloudFormation now provides the aws cloudformation list-stacks command, which enables you to list stacks filtered by stack status. Deleted stacks can be listed for up to 90 days after they have been deleted. For more information, see Describing and Listing Your Stacks (p. 111).	2010-05-15
New features	May 26, 2011	The aws cloudformation describe-stack-resources and aws cloudformation get-template commands now enable you to get information from stacks that have been deleted for 90 days after they have been deleted. For more information, see Listing Resources (p. 116) and Retrieving a Template (p. 116).	2010-05-15
New link	March 1, 2011	AWS CloudFormation endpoint information is now located in the AWS General Reference. For more information, go to Regions and Endpoints in Amazon Web Services General Reference.	2010-05-15
Initial release	February 25, 2011	This is the initial public release of AWS CloudFormation.	2010-05-15

Supported AWS Services

AWS CloudFormation supports the following AWS services and features through the listed resources.

Topics

- Analytics (p. 2479)
- Application Services (p. 2480)
- Compute (p. 2481)
- Customer Engagement (p. 2482)
- Database (p. 2483)
- Developer Tools (p. 2484)
- Enterprise Applications (p. 2485)
- Game Development (p. 2485)
- Internet of Things (p. 2485)
- Machine Learning (p. 2486)

- Management Tools (p. 2486)
- Mobile Services (p. 2488)
- Networking (p. 2488)
- Security and Identity (p. 2490)
- Storage and Content Delivery (p. 2491)
- Additional Software and Services (p. 2492)

Analytics

Amazon Athena (Added in September 2017)

AWS::Athena::NamedQuery (p. 697)

Amazon EMR (Amazon EMR) (Updated in November 2017)

AWS::EMR::Cluster (p. 1501)

AWS::EMR::InstanceFleetConfig (p. 1541)

AWS::EMR::InstanceGroupConfig (p. 1550)

AWS::EMR::SecurityConfiguration (p. 1565)

AWS::EMR::Step (p. 1568)

AWS Data Pipeline (Added in June 2015)

AWS::DataPipeline::Pipeline (p. 1056)

Amazon Elasticsearch Service (Amazon ES) (Updated in September 2016)

AWS::Elasticsearch::Domain (p. 1412)

AWS Glue (Added in October 2017)

AWS::Glue::Classifier (p. 1584)

AWS::Glue::Connection (p. 1588)

AWS::Glue::Crawler (p. 1592)

AWS::Glue::Database (p. 1601)

AWS::Glue::DevEndpoint (p. 1604)

AWS::Glue::Job (p. 1606)

AWS::Glue::Trigger (p. 1632)

AWS::Glue::Partition (p. 1612)

AWS::Glue::Table (p. 1621)

Amazon Kinesis (Updated in November 2017)

AWS::Kinesis::Stream (p. 1727)

AWS::KinesisFirehose::DeliveryStream (p. 1730)

AWS::KinesisAnalytics::Application (p. 1759)

AWS::KinesisAnalytics::ApplicationOutput (p. 1772)

AWS::KinesisAnalytics::ApplicationReferenceDataSource (p. 1777)

Application Services

Amazon MQ (Added in June 2018)

AWS::AmazonMQ::Broker (p. 520)

AWS::AmazonMQ::Configuration (p. 530)

Amazon API Gateway (API Gateway) (Updated in February 2018)

AWS::ApiGateway::Account (p. 534)

AWS::ApiGateway::ApiKey (p. 536)

AWS::ApiGateway::Authorizer (p. 540)

AWS::ApiGateway::BasePathMapping (p. 544)

AWS::ApiGateway::ClientCertificate (p. 545)

AWS::ApiGateway::Deployment (p. 547)

AWS::ApiGateway::DocumentationPart (p. 558)

AWS::ApiGateway::DocumentationVersion (p. 562)

AWS::ApiGateway::DomainName (p. 566)

AWS::ApiGateway::GatewayResponse (p. 573)

AWS::ApiGateway::Method (p. 577)

AWS::ApiGateway::Model (p. 590)

AWS::ApiGateway::RequestValidator (p. 593)

AWS::ApiGateway::Resource (p. 596)

AWS::ApiGateway::RestApi (p. 598)

AWS::ApiGateway::Stage (p. 606)

AWS::ApiGateway::UsagePlan (p. 614)

AWS::ApiGateway::UsagePlanKey (p. 619)

AWS::ApiGateway::VpcLink (p. 620)

Amazon Simple Queue Service (Amazon SQS) (Updated in August 2017)

AWS::SQS::Queue (p. 2133)

AWS::SQS::QueuePolicy (p. 2141)

AWS Step Functions (Step Functions) (Updated in February 2017)

AWS::StepFunctions::Activity (p. 2142)

AWS::StepFunctions::StateMachine (p. 2144)

Compute

Application Auto Scaling (Added in July 2017)

AWS::ApplicationAutoScaling::ScalableTarget (p. 624)

AWS::ApplicationAutoScaling::ScalingPolicy (p. 639)

Amazon EC2 Auto Scaling (Updated in November 2017)

AWS::AutoScaling::AutoScalingGroup (p. 699)

AWS::AutoScaling::LaunchConfiguration (p. 715)

AWS::AutoScaling::LifecycleHook (p. 726)

AWS::AutoScaling::ScalingPolicy (p. 729)

AWS::AutoScaling::ScheduledAction (p. 741)

Amazon Elastic Compute Cloud (Amazon EC2) (Updated September 2018)

AWS::EC2::Host (p. 1153)

AWS::EC2::Instance (p. 1155)

AWS::EC2::LaunchTemplate (p. 1178)

AWS::EC2::PlacementGroup (p. 1218)

AWS::EC2::SpotFleet (p. 1246)

AWS::EC2::VPCPeeringConnection (p. 1303)

AWS::EC2::VPCEndpointServicePermissions (p. 1299)

Amazon Elastic Container Registry (Amazon ECR) (Added in February 2016)

AWS::ECR::Repository (p. 1322)

Amazon Elastic Container Service (Amazon ECS) (Updated in April 2017)

AWS::ECS::Cluster (p. 1327)

AWS::ECS::Service (p. 1328)

AWS::ECS::TaskDefinition (p. 1345)

Amazon Elastic Container Service for Kubernetes (Added in June 2018)

AWS::EKS::Cluster (p. 1382)

Amazon EC2 Systems Manager (SSM) (Updated in June 2018)

AWS::SSM::Association (p. 2148)

AWS::SSM::Document (p. 2152)

AWS::SSM::MaintenanceWindow (p. 2156)

AWS::SSM::MaintenanceWindowTarget (p. 2159)

AWS::SSM::MaintenanceWindowTask (p. 2161)

AWS::SSM::Parameter (p. 2174)

AWS::SSM::PatchBaseline (p. 2177)

AWS::SSM::ResourceDataSync (p. 2185)

AWS Batch (Added in August 2017)

AWS::Batch::ComputeEnvironment (p. 753)

AWS::Batch::JobDefinition (p. 760)

AWS::Batch::JobQueue (p. 772)

AWS Elastic Beanstalk (Elastic Beanstalk) (Updated in November 2017)

AWS::ElasticBeanstalk::Application (p. 1425)

AWS::ElasticBeanstalk::ApplicationVersion (p. 1430)

AWS::ElasticBeanstalk::ConfigurationTemplate (p. 1433)

AWS::ElasticBeanstalk::Environment (p. 1438)

Elastic Load Balancing (Updated in November 2017)

AWS::ElasticLoadBalancing::LoadBalancer (p. 1452)

AWS::ElasticLoadBalancingV2::Listener (p. 1473)

AWS::ElasticLoadBalancingV2::ListenerCertificate (p. 1477)

AWS::ElasticLoadBalancingV2::ListenerRule (p. 1480)

AWS::ElasticLoadBalancingV2::LoadBalancer (p. 1484)

AWS::ElasticLoadBalancingV2::TargetGroup (p. 1491)

AWS Lambda (Lambda) (Updated in November 2017)

AWS::Lambda::Alias (p. 1795)

AWS::Lambda::EventSourceMapping (p. 1793)

AWS::Lambda::Function (p. 1800)

AWS::Lambda::Permission (p. 1813)

AWS::Lambda::Version (p. 1816)

Customer Engagement

Amazon Simple Email Service (Amazon SES) (Added in March 2018)

AWS::SES::ConfigurationSet (p. 2088)

AWS::SES::ConfigurationSetEventDestination (p. 2090)

AWS::SES::ReceiptFilter (p. 2098)

AWS::SES::ReceiptRule (p. 2102)

AWS::SES::ReceiptRuleSet (p. 2118)

AWS::SES::Template (p. 2120)

Database

Amazon DynamoDB (DynamoDB) (Updated in August 2017)

AWS::DynamoDB::Table (p. 1115)

Amazon DynamoDB Accelerator (DAX) (Added in August 2017)

AWS::DAX::Cluster (p. 1070)

AWS::DAX::ParameterGroup (p. 1077)

AWS::DAX::SubnetGroup (p. 1079)

Amazon ElastiCache (ElastiCache) (Updated in August 2017)

AWS::ElastiCache::CacheCluster (p. 1386)

AWS::ElastiCache::ParameterGroup (p. 1393)

AWS::ElastiCache::ReplicationGroup (p. 1395)

AWS::ElastiCache::SecurityGroup (p. 1408)

AWS::ElastiCache::SecurityGroupIngress (p. 1409)

AWS::ElastiCache::SubnetGroup (p. 1410)

Amazon Neptune (Neptune) (Added in May 2018)

AWS::Neptune::DBCluster (p. 1818)

AWS::Neptune::DBClusterParameterGroup (p. 1822)

AWS::Neptune::DBInstance (p. 1824)

AWS::Neptune::DBParameterGroup (p. 1829)

AWS::Neptune::DBSubnetGroup (p. 1831)

Amazon Relational Database Service (Amazon RDS) (Updated in October 2017)

AWS::RDS::DBCluster (p. 1887)

AWS::RDS::DBClusterParameterGroup (p. 1896)

AWS::RDS::DBInstance (p. 1898)

AWS::RDS::DBParameterGroup (p. 1915)

AWS::RDS::DBSecurityGroup (p. 1918)

AWS::RDS::DBSecurityGroupIngress (p. 1922)

AWS::RDS::DBSubnetGroup (p. 1924)

AWS::RDS::EventSubscription (p. 1926)

AWS::RDS::OptionGroup (p. 1929)

Amazon Redshift (Updated in July 2017)

AWS::Redshift::Cluster (p. 1935)

AWS::Redshift::ClusterParameterGroup (p. 1944)

AWS::Redshift::ClusterSecurityGroup (p. 1947)

AWS::Redshift::ClusterSecurityGroupIngress (p. 1949)

AWS::Redshift::ClusterSubnetGroup (p. 1951)

Amazon SimpleDB (Added in February 2011)

AWS::SDB::Domain (p. 2123)

AWS Database Migration Service (Added in July 2017)

AWS::DMS::Certificate (p. 1091)

AWS::DMS::Endpoint (p. 1093)

AWS::DMS::EventSubscription (p. 1102)

AWS::DMS::ReplicationInstance (p. 1105)

AWS::DMS::ReplicationSubnetGroup (p. 1109)

AWS::DMS::ReplicationTask (p. 1111)

Developer Tools

AWS Cloud9 (Added in November 2017)

AWS::Cloud9::EnvironmentEC2 (p. 791)

AWS CodeBuild (Added in December 2016)

AWS::CodeBuild::Project (p. 911)

AWS CodeCommit (Added in October 2016)

AWS::CodeCommit::Repository (p. 931)

AWS CodeDeploy (Updated in November 2017)

AWS::CodeDeploy::Application (p. 935)

AWS::CodeDeploy::DeploymentConfig (p. 937)

AWS::CodeDeploy::DeploymentGroup (p. 940)

AWS CodePipeline (Updated in May 2018)

AWS::CodePipeline::CustomActionType (p. 973)

AWS::CodePipeline::Pipeline (p. 979)

AWS::CodePipeline::Webhook (p. 991)

Enterprise Applications

Amazon **AppStream 2.0** (Added in October 2018)

AWS::AppStream::DirectoryConfig (p. 653)

AWS::AppStream::Fleet (p. 655)

AWS::AppStream::ImageBuilder (p. 660)

AWS::AppStream::Stack (p. 664)

AWS::AppStream::StackFleetAssociation (p. 669)

AWS::AppStream::StackUserAssociation (p. 671)

AWS::AppStream::User (p. 672)

Amazon WorkSpaces (Updated in December 2015)

AWS::WorkSpaces::Workspace (p. 2253)

Game Development

Amazon GameLift (GameLift) (Updated in April 2016)

AWS::GameLift::Alias (p. 1572)

AWS::GameLift::Build (p. 1575)

AWS::GameLift::Fleet (p. 1578)

Internet of Things

AWS IoT (Updated in Septmeber 2018)

AWS::IoT::Certificate (p. 1689)

AWS::IoT::Policy (p. 1691)

AWS::IoT::PolicyPrincipalAttachment (p. 1693)

AWS::IoT::Thing (p. 1694)

AWS::IoT::ThingPrincipalAttachment (p. 1698)

AWS::IoT::TopicRule (p. 1699)

AWS::IoT1Click::Device (p. 1718)

AWS::IoT1Click::Placement (p. 1720)

AWS::IoT1Click::Project (p. 1723)

Machine Learning

Amazon SageMaker (Added in May 2018)

AWS::SageMaker::Endpoint (p. 2040)

AWS::SageMaker::EndpointConfig (p. 2044)

AWS::SageMaker::Model (p. 2050)

AWS::SageMaker::NotebookInstance (p. 2057)

AWS::SageMaker::NotebookInstanceLifecycleConfig (p. 2062)

Management Tools

AWS Auto Scaling (Added in May 2018)

AWS::AutoScalingPlans::ScalingPlan (p. 744)

AWS CloudFormation (AWS CloudFormation) (Updated in June 2018)

AWS::CloudFormation::Authentication (p. 795)

AWS::CloudFormation::CustomResource (p. 800)

AWS::CloudFormation::Init (p. 803)

AWS::CloudFormation::Macro (p. 821)

AWS::CloudFormation::Stack (p. 823)

AWS::CloudFormation::WaitCondition (p. 827)

AWS::CloudFormation::WaitConditionHandle (p. 830)

AWS CloudTrail (CloudTrail) (Updated in August 2017)

AWS::CloudTrail::Trail (p. 865)

Amazon CloudWatch (CloudWatch) (Updated in October 2018)

AWS::CloudWatch::Alarm (p. 874)

AWS::CloudWatch::Dashboard (p. 880)

AWS::Events::EventBusPolicy (p. 896)

AWS::Events::Rule (p. 882)

AWS::Logs::Destination (p. 899)

AWS::Logs::LogGroup (p. 902)

AWS::Logs::LogStream (p. 904)

AWS::Logs::MetricFilter (p. 905)

AWS::Logs::SubscriptionFilter (p. 908)

AWS Config (Updated in April 2018)

AWS::Config::AggregationAuthorization (p. 1028)

AWS::Config::ConfigRule (p. 1037)

AWS::Config::ConfigurationAggregator (p. 1045)

AWS::Config::ConfigurationRecorder (p. 1050)

AWS::Config::DeliveryChannel (p. 1053)

AWS OpsWorks (Updated in November 2017)

AWS::OpsWorks::App (p. 1833)

AWS::OpsWorks::ElasticLoadBalancerAttachment (p. 1839)

AWS::OpsWorks::Instance (p. 1841)

AWS::OpsWorks::Layer (p. 1852)

AWS::OpsWorks::Stack (p. 1867)

AWS::OpsWorks::UserProfile (p. 1882)

AWS::OpsWorks::Volume (p. 1885)

AWS Service Catalog (Updated in May 2018)

AWS::ServiceCatalog::AcceptedPortfolioShare (p. 2066)

AWS::ServiceCatalog::CloudFormationProduct (p. 2067)

AWS::ServiceCatalog::CloudFormationProvisionedProduct (p. 2071)

AWS::ServiceCatalog::LaunchNotificationConstraint (p. 2075)

AWS::ServiceCatalog::LaunchRoleConstraint (p. 2077)

AWS::ServiceCatalog::LaunchTemplateConstraint (p. 2078)

AWS::ServiceCatalog::Portfolio (p. 2080)

AWS::ServiceCatalog::PortfolioPrincipalAssociation (p. 2082)

AWS::ServiceCatalog::PortfolioProductAssociation (p. 2083)

AWS::ServiceCatalog::PortfolioShare (p. 2084)

AWS::ServiceCatalog::TagOption (p. 2086)

AWS::ServiceCatalog::TagOptionAssociation (p. 2087)

AWS Systems Manager (Updated in May 2018)

AWS::SSM::Association (p. 2148)

AWS::SSM::Document (p. 2152)

AWS::SSM::MaintenanceWindow (p. 2156)

AWS::SSM::MaintenanceWindowTarget (p. 2159)

AWS::SSM::MaintenanceWindowTask (p. 2161)

AWS::SSM::Parameter (p. 2174)

AWS::SSM::PatchBaseline (p. 2177)

AWS::SSM::ResourceDataSync (p. 2185)

Mobile Services

AWS AppSync (Added in April 2018)

AWS::AppSync::ApiKey (p. 674)

AWS::AppSync::DataSource (p. 676)

AWS::AppSync::GraphQLApi (p. 684)

AWS::AppSync::GraphQLSchema (p. 687)

AWS::AppSync::Resolver (p. 692)

Amazon Cognito (Added in April 2017)

AWS::Cognito::IdentityPool (p. 996)

AWS::Cognito::IdentityPoolRoleAttachment (p. 1004)

AWS::Cognito::UserPool (p. 1005)

AWS::Cognito::UserPoolClient (p. 1020)

AWS::Cognito::UserPoolGroup (p. 1022)

AWS::Cognito::UserPoolUser (p. 1024)

AWS::Cognito::UserPoolUserToGroupAttachment (p. 1027)

Amazon Simple Notification Service (Amazon SNS) (Updated in November 2016)

AWS::SNS::Subscription (p. 2124)

AWS::SNS::Topic (p. 2128)

AWS::SNS::TopicPolicy (p. 2131)

Networking

Amazon Route 53 (Updated in March 2017)

AWS::Route53::HealthCheck (p. 1953)

AWS::Route53::HostedZone (p. 1960)

AWS::Route53::RecordSet (p. 1965)

AWS::Route53::RecordSetGroup (p. 1972)

Service Discovery (Added in December 2017)

AWS::ServiceDiscovery::Instance (p. 1974)

AWS::ServiceDiscovery::PrivateDnsNamespace (p. 1976)

AWS::ServiceDiscovery::PublicDnsNamespace (p. 1978)

AWS::ServiceDiscovery::Service (p. 1979)

Amazon Virtual Private Cloud (Amazon VPC) (Updated in November 2017)

AWS::EC2::CustomerGateway (p. 1137)

AWS::EC2::DHCPOptions (p. 1139)

AWS::EC2::EgressOnlyInternetGateway (p. 1142)

AWS::EC2::EIP (p. 1144)

AWS::EC2::EIPAssociation (p. 1146)

AWS::EC2::FlowLog (p. 1150)

AWS::EC2::InternetGateway (p. 1177)

AWS::EC2::NatGateway (p. 1199)

AWS::EC2::NetworkAcl (p. 1202)

AWS::EC2::NetworkAclEntry (p. 1203)

AWS::EC2::NetworkInterface (p. 1208)

AWS::EC2::NetworkInterfaceAttachment (p. 1214)

AWS::EC2::NetworkInterfacePermission (p. 1216)

AWS::EC2::Route (p. 1219)

AWS::EC2::RouteTable (p. 1223)

AWS::EC2::SecurityGroup (p. 1225)

AWS::EC2::SecurityGroupEgress (p. 1234)

AWS::EC2::SecurityGroupIngress (p. 1238)

AWS::EC2::Subnet (p. 1270)

AWS::EC2::SubnetCidrBlock (p. 1273)

AWS::EC2::SubnetNetworkAclAssociation (p. 1275)

AWS::EC2::SubnetRouteTableAssociation (p. 1277)

AWS::EC2::VPC (p. 1285)

AWS::EC2::VPCCidrBlock (p. 1288)

AWS::EC2::VPCDHCPOptionsAssociation (p. 1291)

AWS::EC2::VPCEndpoint (p. 1293)

AWS::EC2::VPCGatewayAttachment (p. 1301)

AWS::EC2::VPCPeeringConnection (p. 1303)

AWS::EC2::VPNConnection (p. 1313)

AWS::EC2::VPNConnectionRoute (p. 1316)

AWS::EC2::VPNGateway (p. 1318)

AWS::EC2::VPNGatewayRoutePropagation (p. 1320)

Security and Identity

AWS Certificate Manager (ACM) (Added in August 2016)

AWS::CertificateManager::Certificate (p. 788)

AWS Directory Service (Updated in December 2015)

AWS::DirectoryService::MicrosoftAD (p. 1083)

AWS::DirectoryService::SimpleAD (p. 1087)

Amazon Inspector (Added in December 2017)

AWS::Inspector::AssessmentTarget (p. 1683)

AWS::Inspector::AssessmentTemplate (p. 1684)

AWS::Inspector::ResourceGroup (p. 1687)

Amazon GuardDuty (Updated in May 2018)

AWS::GuardDuty::Detector (p. 1641)

AWS::GuardDuty::Filter (p. 1642)

AWS::GuardDuty::IPSet (p. 1652)

AWS::GuardDuty::Master (p. 1647)

AWS::GuardDuty::Member (p. 1649)

AWS::GuardDuty::ThreatIntelSet (p. 1654)

AWS Identity and Access Management (IAM) (Updated in April 2017)

AWS::IAM::AccessKey (p. 1657)

AWS::IAM::Group (p. 1658)

AWS::IAM::InstanceProfile (p. 1660)

AWS::IAM::ManagedPolicy (p. 1662)

AWS::IAM::Policy (p. 1666)

AWS::IAM::Role (p. 1670)

AWS::IAM::User (p. 1678)

AWS::IAM::UserToGroupAddition (p. 1681)

AWS Key Management Service (AWS KMS) (Updated in October 2017)

AWS::KMS::Alias (p. 1786)

AWS::KMS::Key (p. 1788)

AWS WAF (Updated in May 2017)

AWS::WAF::ByteMatchSet (p. 2188)

AWS::WAF::IPSet (p. 2193)

AWS::WAF::Rule (p. 2197)

AWS::WAF::SizeConstraintSet (p. 2200)

AWS::WAF::SqlInjectionMatchSet (p. 2205)

AWS::WAF::WebACL (p. 2209)

AWS::WAF::XssMatchSet (p. 2215)

AWS::WAFRegional::ByteMatchSet (p. 2220)

AWS::WAFRegional::IPSet (p. 2225)

AWS::WAFRegional::Rule (p. 2229)

AWS::WAFRegional::SizeConstraintSet (p. 2232)

AWS::WAFRegional::SqlInjectionMatchSet (p. 2237)

AWS::WAFRegional::WebACL (p. 2241)

AWS::WAFRegional::WebACLAssociation (p. 2247)

AWS::WAFRegional::XssMatchSet (p. 2248)

Storage and Content Delivery

Amazon CloudFront (CloudFront) (Updated in November 2017)

AWS::CloudFront::CloudFrontOriginAccessIdentity (p. 855)

AWS::CloudFront::Distribution (p. 831)

AWS::CloudFront::StreamingDistribution (p. 858)

Amazon Elastic Block Store (Amazon EBS) (Updated in April 2017)

AWS::EC2::Volume (p. 1279)

AWS::EC2::VolumeAttachment (p. 1283)

Amazon Elastic File System (Amazon EFS) (Updated in August 2017)

AWS::EFS::FileSystem (p. 1375)

AWS::EFS::MountTarget (p. 1379)

Amazon Simple Storage Service (Amazon S3) (Updated in November 2017)

AWS::S3::Bucket (p. 1985)

AWS::S3::BucketPolicy (p. 2037)

Additional Software and Services

AWS Billing and Cost Management (Billing and Cost Management) (Added in May 2018)

AWS::Budgets::Budget (p. 775)

Release History for AWS CloudFormation Helper Scripts

The following table describes the changes to the aws-cfn-bootstrap package, which contains the AWS CloudFormation helper scripts.

> **Note**
> The AWS CloudFormation helper scripts are preinstalled on Amazon Linux AMI images. The download packages listed in the table apply to other Linux/Unix distributions and Microsoft Windows (2008 or later). To learn how to use the helper scripts, see CloudFormation Helper Scripts Reference (p. 2354).

You can also download the latest version of the helper scripts at the following links. These links redirect to the most recent version of the helper scripts listed in the table below.

- RPM
- RPM (Source files)
- TAR.GZ
- ZIP
- MSI (32-bit Windows)
- MSI (64-bit Windows)

Version	Release Date	Change Description	Download Packages
1.4-30 (Latest; recommended)	3/21/2018	• Added additional retries on specific network errors. • Improved `cfn-hup` logging.	• RPM • RPM (Source files) • TAR.GZ • ZIP • MSI (32-bit Windows) • MSI (64-bit Windows)
1.4-29	2/12/2018	Extending support for newer AWS regions.	• RPM • RPM (Source files) • TAR.GZ • ZIP • MSI (32-bit Windows) • MSI (64-bit Windows)
1.4-27	1/24/2018	Extending support for newer AWS regions.	• RPM • RPM (Source files) • TAR.GZ • ZIP

Version	Release Date	Change Description	Download Packages
			• MSI (32-bit Windows) • MSI (64-bit Windows)
1.4-24, 1.4-26	10/12/2017	Fixed an incompatibility for customers using an older version of Python.	• RPM • RPM (Source files) • TAR.GZ • ZIP • MSI (32-bit Windows) • MSI (64-bit Windows)
1.4-23	10/3/2017	• Fixed datetime serialization issue. • Fixed issue logging non-ASCII characters.	• RPM • RPM (Source files) • TAR.GZ • ZIP • MSI (32-bit Windows) • MSI (64-bit Windows)
1.4-22	9/14/2017	Changed `umask` default value from `0` to `0022`.	• RPM • RPM (Source files) • TAR.GZ • ZIP • MSI (32-bit Windows) • MSI (64-bit Windows)
1.4-21	8/31/2017	Added the `umask` parameter for the cfn-hup daemon, with a default value of `0`.	• RPM • RPM (Source files) • TAR.GZ • ZIP • MSI (32-bit Windows) • MSI (64-bit Windows)
1.4-20	8/2/2017	• Set 0700 permissions to the `/var/lib/cfn-hup/data` directory. • Set 0700 permissions to the `/var/lib/cfn-init` directory. • Ensure that we remove all permissions for group and world whenever we update the `metadata_db.json` and `resume_db.json` files.	• RPM • RPM (Source files) • TAR.GZ • ZIP • MSI (32-bit Windows) • MSI (64-bit Windows)
1.4-19	7/20/2017	• Changed the data format stored into `metadata_db` and `resume_db` files from shelf to JSON. • Set 0600 permissions to the `/var/lib/cfn-init` directory.	• RPM • RPM (Source files) • TAR.GZ • ZIP • MSI (32-bit Windows) • MSI (64-bit Windows)

AWS Glossary

For the latest AWS terminology, see the AWS Glossary in the *AWS General Reference*.
